The tuberculous lesions in the 11 per cent. were as follows. Seven patients showed enlarged glands, four of these were cervical, one abdominal glands, and two intrathoracic glandular enlargements. One patient was a tuberculous spinal case. Six of the patients showed pulmonary lesions, two of these also showed glandular enlargements, while from four of them T.B. were found in the sputum. The syphilitic lesions were definite in most of the cases and are described individually.

2. *Does Syphilis Predispose to Tuberculous Infection?*

A study of the pathogenesis of tuberculosis suggests a similar route of spread to that taken by syphilis. It has been pointed out[15] that the initial sore is commonly unobserved in tuberculosis, but that later there is a gradual spread by the lymphatic stream, for the lymphatic gland which has arrested a polymorph carrying T.B. may caseate and discharge its contents into the lymphatic stream. In the experimental infection of a guinea-pig it is quite easy to trace the spread of tuberculosis following the lymphatic system. In an address on Tuberculosis of the Lymphatic System, Sir Robert Philip[15] describes the extension from the glandular system to the viscera. He points out that this may take place by the thoracic duct or by direct extension from an affected gland into a bronchus or even into a blood-vessel. This is precisely the same route of infection as that chosen by the spirochæte. The only difference in the spread of the two infections is that the spirochæte is much the quicker of the two. Among the cases described by Sir Clifford Allbutt[16] was one where glands were found in the mesentery, mesocolon, and mediastinum of a man who died with a chancre, while the spleen was enlarged, so that in syphilis the spirochæte must reach the viscera in the first weeks after infection.

In dealing with the incidence of inherited syphilis among the tuberculous we find a percentage of 11, while the percentage among a normal child population is under 10. This alone would suggest that inherited syphilis plays only a small part in the production of tuberculosis. It is agreed that most people become tuberculised in childhood, but only a small proportion of those who have made acquaintance with T.B. become tuberculous or suffer from tuberculosis. Presumably in most children the T.B. lie latent, and[17] are found in the lymph nodes or lymphatic glands of the mediastinum in children who have died from other causes. In syphilitic children these same glands have already been infected by the spirochæte, for the spirochæte is very general in its distribution. There has been a pre-tuberculous infecting agent traversing the same route as the T.B. would take.

The lymphatic glands, already somewhat enlarged, can readily arrest any polymorph carrying T.B., and a spread from an enlarged lymphatic gland is now very easy. The whole way of spread is, as it were, ready at an early age for an invasion by T.B., and most of the children found with double infections are under school age. The greatest number of double infections were found among those who suffered from enlarged tuberculous lymphatic glands and the spirochæte was there first. It should be remembered that the spirochæte would not be observed, because at the age at which a child would die from tuberculosis the spirochæte would be difficult to find. But the morbid process due to the spirochæte can be found and the lesions created by the T.B. can also be found.

It should be kept in mind that in general syphilis favours viscera not readily attacked by tuberculosis—e.g., syphilitic disease of the liver is common, but tuberculous disease of the liver is uncommon, and, vice versa, tuberculosis of the lung is common, but syphilis of the lung is relatively uncommon. All pathologists can report post-mortems where the effects of the two diseases are seen, but careful examination as to the existence of the morbid processes of syphilis and tuberculosis in the same organ does not appear to have received much attention. The lymphatic glands are the organs wherein both infections might readily be found to coexist or wherein there might be an implantation of T.B., perhaps on a gummatous gland. Hollander and Narr[5] mention gummatous lymph nodes in the post-mortem report of a patient who died from a general tuberculosis and who suffered also from syphilis. I have been unable to find any other reference to the two morbid processes being found in the same organ.

---

* THE LANCET, 1922, ii., 1376.

How far syphilis predisposes to subsequent infection by the T.B. is not readily determinable from an investigation such as this. These children do not die from tuberculosis. If all patients suffering from tuberculosis under 4 years of age were investigated by W.R., and those who die by careful post-mortem examination, something nearer the truth might be obtained. One should note that in tuberculosis the factor which determines the establishment of disease in the child is the dose or the oft-repeated infection by the T.B. A minute dose will only render the child sensitive to tuberculin, while a larger dose or repeated doses will produce disease. I would emphasise that the question is: Will the minute dose of T.B., insufficient to produce more than tuberculin sensitiveness in the normal child, produce tuberculosis in a syphilitic infant?

We cannot even attempt to guess at the truth without complete data from the early deaths from tuberculosis. An interesting observation as it affects the adult is found in the *British Medical Journal* Epitome, Feb. 9th, 1924. J. W. Samson, in Berlin, examined 1300 prostitutes for tuberculosis. Of W.R. positive prostitutes 12·5 per cent. showed signs of active tuberculosis, whereas only 10·7 per cent. of the W.R. negatives did so. Bronfenbrenner[18] likewise attempted to determine the incidence of tuberculosis among a syphilitic population. With a tubercle antigen he examined the sera of 193 syphilitics, and found 83 positive, or 43 per cent.; 55 of the 83 showed clinical signs of tuberculosis. Using the same tubercle antigen, he found 23·15 per cent. among 432 negative Wassermann reactors to give a positive test for tuberculosis. The conclusion he came to was that tuberculosis was readily implanted on a luetic soil. My own figures are small, and the figure of 11 per cent. positive Wassermann reactors does not allow one to state more than that, considering the method of spread of both diseases to be the same, there might be some slight influence favourable to the implantation of T.B. on a syphilitic terrain.

Description of Cases.

CASE 1.—J. P., aged 6 years. Had excision of glands in the neck in 1921 and 1922. She was admitted to the sanatorium on Oct. 4th, 1922. She had three large cold abscesses ready to break down, one submental, one at the angle of the jaw, and one pre-auricular. The chest showed considerable dullness down the right side, and many crepitations and rhonchi could be heard. She was a mouth-breather, the bridge of the nose was rather flat, the uvula was ulcerated and necrosing, while there was notching of the upper incisors, and Moon's teeth were also noted. The W.R. was definitely positive. The father had been in the army, and this child was born after he was home on leave, the older children being healthy. Sputum showed a few T.B. on concentration. The epitrochlear glands were enlarged. There were shotty glands in the posterior triangles. Treatment by "914" injections and ung. hydrarg. was instituted. The patient began to improve at once. The abscesses broke down but healed very rapidly, and the resulting scars are not at all marked or keloid. The W.R. did not become negative till after a second full course of treatment. The child gained weight steadily. Detuberculisation by tuberculin ointment is being steadily pursued, and the result is satisfactory.

CASE 2.—W. M., aged 8. At 4 years of age he had his right eye enucleated, cause unknown. His glands began to swell two years ago, and there is now a discharging sinus. Small shotty glands are to be felt in both posterior triangles. Both apices are retracted and the veins much dilated over the chest. A few crepitations could be heard at the bases. No T.B. were found, but skin reaction was positive. A guinea-pig inoculation from the discharging sinus failed to produce tuberculosis. His left eye showed an interstitial keratitis and slight posterior synechiæ of the iris. The bridge of the nose was much flattened, and the epitrochlear glands were enlarged. Teeth very good. The W.R. was strongly positive. He was admitted in September, 1922, and discharged in May, 1923. He had a full course of "914" and ung. hydrarg. The W.R. was reduced to a weak positive, the glands in the neck gradually disappeared, he gained one stone in weight, and the chest condition dried up completely. The interstitial keratitis cleared away, but the iris showed atrophic edges and was fixed posteriorly to the lens in places.

CASE 3.—M. R., aged 10. This patient was sent to "Glenlomond" with enlarged glands on both sides of the neck, some cough, and spit. There was a keloid scar on the right side of the neck at the site of a previous excision; her step-father has tuberculosis. Sensitiveness to tuberculin was marked. She presented few signs of congenital syphilis. The W.R. was strongly positive, the epitrochlear glands were enlarged, and she presents Sabouraud's sign on both upper first molars. (This sign has been discredited in some quarters, and it is difficult to attach a correct value to it. It consists of the presence of an extra spur of cusp on the inner side of the first upper molar.) She was given a full course of "914" intravenously and intramuscularly, and after a follow-up course the W.R. became negative. The glands disappeared and the patient gained steadily in weight. She has gradually been detuberculised by tuberculin ointment, which was not used till she had a negative W.R.

CASE 4.—S. M., aged 8, admitted April 20th, 1922, and discharged in May, 1923. She had cough and spit and enlarged glands in the neck. Her sputum showed a few T.B., there were crepitations over both lungs, and her finger-tips were clubbed. There was a small scar by a previous breaking down of a cervical gland. Her specific signs were flattening of the bridge of the nose and pegged teeth, while the W.R. was strongly positive. She had two courses of "914" and ung. hydrarg. The glands disappeared, the chest cleared up, the veins of the chest became less prominent, and the only impairment seemed to be a comparatively flat right upper lobe. A small amount of sputum remained, but this failed to show T.B. She gained one stone in weight. Her W.R. became negative. Detuberculisation by tuberculin was not practised in this patient. In the case of this child the doses of "914" had to be very small, the temperature rising very readily after the drug was given. She never got more than 0·1 g. at a time, and indeed began with 0·05 g.

CASE 5.—P. F., aged 6. An advanced case of tuberculosis, and has had breaking down of glands in the neck. She shows a depressed bridge of the nose, and her teeth are pegged and notched. Molars showed Moon's characteristics. W.R. is positive. She has crepitations down both sides and the sputum is T.B. plus. She was given a small course of "914." No improvement was found in her pulmonary condition. Treatment had to be omitted in this case.

CASE 6.—J. S., aged 6. This patient is sensitive to tuberculin, and shows only the evidence of thoracic glandular enlargement. Specific signs are not marked, the dentition is irregular, and the teeth pegged, but the W.R. was strongly positive. The child readily takes bronchitis, but T.B. were never found. She had a full course of "914" and ung. hydrarg. till she became negative. She gained in weight and was discharged well.

CASE 7.—A. C., aged 7. The condition was much the same as the previous case. There was evidence of enlarged thoracic glands, some sputum, and guinea-pig inoculation produced tuberculosis. The child was not left with us, and therefore had no treatment.

CASE 8.—A. S., aged 5. Enlarged cervical glands, many crepitations at the bases, a few T.B. in the sputum, slight ozæna, W.R. positive. Child had a full course of "914" and ung. hydrarg. She has now been under observation for nearly a year, and is slowly improving.

CASE 9.—C. S., aged 10. Curvature of spine. Congenital signs were the various dental anomalies and the W.R. was positive. He ran a slight temperature every night. This disappeared after treatment by "914" and ung. hydrarg. He was kept for two years and desensitised to tuberculin by tuberculin ointment.

CASE 10, aged 17 years, was always delicate. Her abdominal glands were removed when she was 12 years of age, and four years after she was admitted to the sanatorium. Her teeth had all been removed and nothing could be noted of a specific nature. Her W.R. was strongly positive. Chest showed evidence of enlarged bronchial glands. She was given "914" and immediately had rises of temperature which compelled us to stop treatment. Any attempt at treatment by "914" led to increase in temperature which would persist for many days. She was put on ung. hydrarg. and this seemed to suit her. She gained weight steadily and went home much improved.

CASE 11.—A child of 12 years, deaf, and with interstitial keratitis and perfect Hutchinson's teeth. Her father died of pulmonary tuberculosis. W.R. is, of course, positive.

There are enlarged glands in the neck and a few crepitations on the right side of the chest, but no T.B. have been found. Treatment has only lately been instituted. Sensitiveness to tuberculin in this case is very slight.

Besides the 100 children examined I have found another most interesting case of a girl of 20, sent as a hip-joint disease (?) after partial excision of the joint. The early history is not quite clear, but in 1918 she was sent to the Royal Infirmary, Dundee, under Mr. D. M. Greig. When he saw her the right hip-joint had been opened up and was discharging freely, while the general condition of the patient was very poor. Her W.R. was positive, and she healed in a marvellous way on anti-syphilitic treatment; so quick and good was the recovery that Mr. Greig was inclined to doubt the tuberculous nature of the infection. When she came to me her serum reaction was returned as partial. She improved on mercury and again walks quite well.

Included in the 100 children I have one child with caseous glands in the neck and from whom T.B. were obtained, who might be syphilitic, although the W.R. was negative and only partial after a provocative injection. This child, 5 years of age, showed some dullness of a cornea and had a posterior synechia of the iris. The child improved on mercury and tuberculin ointment and went home well.

3. *Effect of Anti-Syphilitic Treatment.*

How far can the conditions be modified by anti-syphilitic treatment? It depends on the amount of tuberculous disease.

Case 6, where there was a big tuberculous infection, was not improved, and Case 10 seemed to be worse when the arsenical preparations were exhibited. In Case 4 treatment had to be very cautious. The other cases improved. It is necessary to proceed with caution.

I frankly admit to being afraid to use potassium iodide. It never can cure syphilis, but it may open up tissue spaces and allow the arsenical compounds a chance. It may also allow of a further and easier spread of T.B.

The percentage of cases of inherited syphilis among tuberculous children may seem small when one remembers the statements made by older writers—e.g., that children with inherited syphilis often show signs of tuberculous disease of joints. It may be that some of these cases were syphilitic only; in fact, those cases which improved with Scott's dressing probably were syphilitic only. Cases of bilateral infection of joints are always suspicious of syphilis, and cases where tuberculosis can almost certainly be excluded do not reach me.

Conclusions.

1. The case against syphilis as predisposing to a subsequent tuberculous infection is not proven.
2. Anti-syphilitic remedies must be used with caution.

I have to record my thanks to Prof. W. J. Tulloch, University College, Dundee, to whom I am indebted for the serological reactions.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF COMPARATIVE MEDICINE.

A MEETING of this section was held on Nov. 26th, Prof. F. T. G. HOBDAY, the President, occupying the chair.

PUERPERAL SEPTICÆMIA IN CATTLE.

Mr. LESLIE PUGH read a communication on this subject. He said that during the last 20 years there had been little or no decrease in the incidence and morbidity of puerperal sepsis in the human being, and it had occurred to him that some facts noted in the parturition of animals might afford some light on the human problem. In the course of his practice he frequently encountered metritis which was already apparent at the birth of the calf, though at that time the mother showed no systemic symptoms. A few days later, however, there were signs of septic infection. An important fact was that in most cases of streptococcal fever the cows had not been handled by either the veterinarian or the herdsman; especially significant was this in view of the readiness, in the case of the human subject, to blame either doctor or midwife in cases of puerperal sepsis for having, by unclean methods, conveyed the infection to the mother. Mr. Pugh devoted special attention to the syndromè caused by infection with Bang's bacillus. The first sign of this was a delay in parturition. After birth at full time of an apparently normal calf there was retention of the placenta. Owing to many cattle devouring their placenta, the failure to find the placenta was not taken much note of. Within a few days there appeared a brownish-red vaginal discharge, and if at this stage no abnormality had been noticed, the further developments were serious, including evidences of a general toxæmia, and in spite of treatment at this stage death was liable to occur. If the veterinarian were called in within an hour or two of the birth, he would manually separate the placenta, giving particular attention to each cotyledon, and if this was followed by washing out with a weak antiseptic solution, recovery would probably be uneventful. From these cases organisms of the coli group had been recovered by blood cultivation; at a later stage this was overgrown by crowds of saprophytes. If there were delay in skilled treatment, the chance of success was much diminished, for streptococci would probably have dominated the field. *B. coli* infection occurred also in human cases of puerperal fever, and bacilluria in which this organism is present was frequent in pregnancy.

By what means did streptococci gain access to the region and multiply? He repeated that in cattle, normally, labour was unattended, yet coli organisms were present before labour took place, and presumably they were carried by the lymph or the bloodstream. He suggested that they found their way into the uterus through the suction action produced by the alternate contraction and relaxation of the uterus. This could be well demonstrated in the case of the cow, as when a considerable fragment of membrane protruded from the uterus it would make a 4-inch excursion to and fro. He threw out the suggestion that some such suction action in the human mother might account for the intrusion of organisms into the genital region.

Discussion.

Prof. LOUISE MCILROY agreed that there still remained an enormous gap in knowledge as to the mode of infection in these cases and the route which the virus took. *B. coli* was a most difficult organism to do research work on. The question of the invasion of putrefactive organisms was a very interesting one. She believed the majority of cases of puerperal sepsis started as a putrefactive condition due to faulty drainage from the uterus. These patients ran an ordinary temperature for several days, and then there was a lighting up, indicating the occurrence of a secondary infection. Every effort should be made to induce the uterus to contract properly. If in the uterus there were retained debris and blood-clot and possibly retained membrane, then the putrefactive organisms entered the uterus, and it was difficult to get rid of them. An important prophylactic measure in these cases, therefore, was to prevent the fatigue of the uterus by hurrying up the delivery, and, where such fatigue was likely to occur, getting the patient into a good condition of resistance by care at antenatal clinics. There should be free drainage of the uterus, but she did not suggest, however, that there should be local interference with the uterus in acute streptococcal infection. The insertion of iodine pessaries had in her hands been very successful.

Manipulations Not a Cause of Sepsis.

With regard to direct infection of the genital canal by manipulative measures, Prof. McIlroy said that the longer she worked on obstetrics the less she believed that organisms were introduced into the genital canal by manipulative interference. This view was supported by the fact that despite the advances in aseptic and antiseptic measures and general technique during that time, the maternal mortality-rate had not been materially reduced. A further confirmation was found in the observation that when operative interference in these cases was called for, they did not necessarily go septic—indeed, the great majority ran a perfectly normal puerperium. In addition, it had been reported that though most cattle were not attended at parturition, sepsis at that period was not uncommon. It was necessary, therefore, to look for other sources of sepsis. These she regarded as three in number: lowered immunity of the patient, lacerations of the genital canal, and latent infection in the patient herself, which might coexist with the first of these. The suction action of the uterus at this time, which Mr. Pugh had mentioned, might be operative in the human subject, but it was known that even if a portion of membrane was left behind, there was not much trouble provided the uterus contracted; it was when portions protruded from the cervix that trouble ensued.

She believed that in most of the cases the toxæmia was of intestinal origin, and toxæmia caused fatigue, and hence was at the root of the uterus contracting inadequately. She knew of no hospitals where there were not cases of febrile puerperium, and she was sure there were some lacerations of the vagina and cervix which were not treated properly, because it was not easy to diagnose them. It was well known that when the general immunity was lowered, small events which ordinarily would be unnoticed, such as a whitlow or a poisoned finger-nail, produced a general septic condition which might be very grave at this time. When positive results were obtained in the search for the *B. vaginæ*, she thought vaccines should be employed. Appendicitis and pyelitis were not uncommon complications of pregnancy, and the reason they did not loom larger in the puerperium was probably that the patients had gradually rendered themselves more or less immune to them. In the human, lactic acid pessaries were found useful; the normal bacilli of the vagina generated lactic acid, and the pessaries reinforced this, or supplied a deficiency. Finally, Prof. McIlroy said she was sure the sterilisation of vulva and vagina was a very misguided form of treatment, and was quite unnecessary in normal cases. And even washing out with a weak antiseptic might remove also the protective bacilli from the region.

Dr. M. J. ROWLANDS did not agree that there had been but little reduction in the deaths from puerperal sepsis in the last 20 years; formerly the deaths from the condition were seriously frequent. Intestinal intoxication he regarded as the chief factor in lowering the general resistance, and with the exception of *B. coli* he thought infection in the cases under discussion must be sought from outside the body. The policy of non-interference during the human puerperium was taught to him by Dr. Herbert Spencer, and he was sure it was the sound one.

Dr. REMINGTON HOBBS said he had seen several cases of puerperal sepsis which had been due to *B. coli*, but in the cervical smears he found staphylococci and streptococci also. Dr. Robert Donaldson examined for him 100 cases of urine from pregnant women, and in 23 it contained *B. coli*. The use of potassium citrate and sterilised glycerine locally obviated puerperal sepsis in all of them. Coli infection of the urinary tract was practically always accompanied at the puerperium by infection of the genital tract by the organism, hence the need for especial cleanliness.

Prof. ALFRED WILD spoke from a long experience in bovine practice. He found that cows which yielded milk were usually well looked after, but parturient cows were neglected and left largely to take care of themselves. Hence their hind quarters were in a very neglected state, and the entry of *B. coli* was a very easy matter. In treating these cases he advocated irrigation of the uterus by a very mild antiseptic, followed by introducing the hand and rotating the uterus, which manœuvre would usually start it contracting.

Dr. ADRIAN STOKES said he did not think the protective capacity of the cow was abolished by parturition. In many cases he had found streptococci in the lochia, and yet puerperal sepsis was not manifest. A woman who normally carried these organisms seemed to immunise herself, and was able to compete with the streptococci as they grew in her lochia. There was sound reason against the employment of strong antiseptic solutions. They did not reach all the organisms, especially those in crypts, and even if some were killed off, many remained, and they quickly multiplied to formidable proportions again. Moreover, A. Fleming had shown that antiseptics damaged the leucocytes, and hence seriously lowered the individual's bactericidal powers.

Prof. WOODRUFF (Australia) said the bacillus of contagious abortion was the commonest cause of the retention of the fœtal membrane. In Australia no calf-boxes for the cow nor foal-boxes for the mare were used; parturition took place in the dry open air and sunshine, and pathological conditions of the uterus in those animals were very rare in that country. He spoke highly of the results of using lactic acid in cystitis and in cases where puerperal infection was likely to occur.

Mr. W. E. LITTLE agreed that the contagious abortion bacillus was far the commonest cause of retention of fœtal membranes in cattle. He had had best results from flushing the uterus with normal saline.

The PRESIDENT spoke of the various shapes of uterus in different animals. In the mare, the placental membrane should be removed as soon as possible. In the cow, the membranes were left until they were ready to come away of themselves. If they were removed too quickly, laceration was very liable to occur, followed by septic metritis. In the case of the cat, the dog, and the sow, care had to be taken not to leave behind any placental membrane of any of the fœtuses. For years the practice had been to induce their removal by syringing, but only with very weak solutions, such as dilute permanganate of potash, or peroxide of hydrogen, or normal saline.

Mr. PUGH briefly replied.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

EXHIBITION OF CASES AND SPECIMENS.

THE Society opened its fourth session on Nov. 28th, under the presidency of Colonel L. W. HARRISON.

Syphilitic Œdema of Lip and Nose.

Dr. DENNIS VINRACE showed a man, aged 41, who 20 years ago had syphilis, for which he had been treated at various places. He came to the exhibitor with severe œdema of the upper lip, with much irritation of that and the lower lip and nose. The lips were also fissured, and the tongue enlarged, infiltrated, and leucoplakic. The Wassermann test was strongly positive. Dr. Vinrace had treated him solely on 0·2 g. doses of bismuthyl, and the patient said this had given him more benefit than any other method. In five months his weight had increased by 24 lb.

Dr. David Lees drew attention to the man's septic denture, and suggested its abandonment. He advised careful watching of the patient's condition, owing to the tendency of bismuth preparations to cause kidney trouble. A period of substitution of salvarsan for bismuthyl might be beneficial.—Dr. Margaret Rorke said she had seen very acute and persistent tongue and lip cracks clear up well under colloidal sulphur and under intramin.—Dr. B. B. Sharp considered the removal of the septic mouth focus as the main need in the treatment of the case.

Dr. Vinrace also showed a man, aged 42, with a tuberculide of the face which was clearing up under CO_2 snow. Though the complement-fixation test for tubercle was negative—as also was the Wassermann—and there was no family history of tuberculosis, he still considered it tuberculide.

Persistent Infective Hypertrophy of Labium.

Dr. Rorke showed a young woman who attended hospital a month ago with acute œdema of the labium majus, probably syphilitic. She was doing very well on ordinary treatment, as very little rash remained, but the hypertrophy of the labium would probably persist.

Dr. T. Anwyl Davies said he had known cases of similar hypertrophy due to syphilis persist after the acute stage had passed.

Gonococcal Periostitis of Tibia.

Mr. V. E. Lloyd exhibited a man presenting what was regarded as gonococcal periostitis of the tibia. The patient was infected with gonorrhœa in March, 1923, and a month later had acute prostatitis. Two months later all the symptoms had subsided, the prostate seemed of normal size, and its secretion was normal. Last March, however, there was a slight return of the discharge, though the prostate and its secretion were then normal. There was at this date a complaint of pain in the centre of the left calf. Treatment with vaccines had very little effect. A skiagram taken two months ago showed a small periosteal node on the outer aspect of the upper end of the tibia. Wassermann was negative. Considerable improvement had followed the recent use of a gonococcal and mixed vaccine.

Dr. Lees inclined to the view that this was a congenital syphilitic condition; there was what seemed to be a syphilitic periostitis all along the tibia.

The President remarked that the Wassermann test being negative did not exclude syphilis.

A Case for Diagnosis.

Dr. Lees showed a man, aged 53, who came with a condition of knee, ankle, and wrist joints, the nature of which seemed obscure. Twenty years ago the man had gonorrhœa, and in the following three years he had two recurrences. Two years later he had arthritis in the joints named, and 12 and four years ago respectively he had synovitis of knees. There was no history of syphilis, and Wassermann was negative. On admission to hospital there was no palpable enlargement of the prostate, but the left vesicle was slightly indurated and nodular. There was neither frequency nor urgency of micturition, and the complement-fixation test for gonorrhœa was negative. There was heavy albuminuria, and the urine contained some coliform bacilli. The joints resembled Charcot joints in appearance; there was some choroiditis with commencing optic atrophy in both eyes; hence it might be that condition.

A Curious Tongue Condition.

Dr. G. B. Dowling presented a man, aged 45, who noticed, nine years ago, a small growth in the left lateral aspect of the tongue, and a similar lesion occurred later on the other side. Then followed small masses on the dorsum of the tongue, and they had gradually increased in size. The masses were in the form of a wedge pointing anteriorly, and the consistence was that of indiarubber. His difficulty was in deciding whether the condition was a tertiary, deep sclerous glossitis of the tongue, or some non-syphilitic condition. He inclined to believe it was median rhomboidal glossitis, which was first described in 1914 by Brocq. Wassermann was negative, and there was no history of syphilitic infection.

Dr. Wilfrid Fox said this tongue did not present the translucent, opalescent aspect usual in tertiary superficial glossitis. The most important element in this case was the septic one; his septic teeth should be removed. It would be of much assistance if a small piece of tongue could be examined microscopically.—The President referred to a tongue case, regarded as syphilitic, and so treated, which was later proved to be columnar-celled carcinoma.

Pleurisy Clearing Up During Syphilis.

Major A. T. Frost described the case of a man who came for treatment of a syphilitic sore and rash while suffering acute pleurisy. Six hours after the first antisyphilitic injection there was a pronounced exacerbation of the pleurisy, and it was gone next morning. There had been no treatment of any kind before the one injection.

Colonel Harrison was unanimously re-elected as President at the meeting.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A clinical meeting of this Society was held in the Medical Out-Patient Department of the Royal Infirmary, Edinburgh, on Nov. 19th, Sir David Wallace being in the chair.

Exhibition of Cases and Specimens.

Mr. Quarry Wood showed two cases: (*a*) *Sarcoma of the proximal end of the humerus.* The patient gave a history of swelling of the shoulder of six weeks' duration, which gradually increased. X ray examination showed a sarcoma to be present. The arm was removed by the interscapulo-thoracic amputation, the posterior method of Littlewood being employed. It was pointed out that this method had the advantage that the shoulder fell away easily, leaving the large vessels standing out in such a way that they could be easily dealt with. Also by this method the position of the patient had not to be changed during the operation. The patient made a good recovery, and was discharged on the fifteenth day. (*b*) *Carcinoma of the rectum.* The case was of about a year's duration in a man aged 56. The growth was movable and favourable for excision. A preliminary operation was first performed, at which colostomy was carried out; at this time the mass was found to be free and without secondary growths. The anæsthetic in this case was of note—a "twilight sleep" combined with spinal anæsthesia. At the second operation, when a radical operation was performed, the patient was in a perfectly natural sleep. There was little post-operative shock, and the patient made a good recovery.

Sir Harold Stiles showed two cases of *hypertrophic tuberculosis of the ileo-cæcal region.* The first was of a girl who had had an anastomosis of the ileum and transverse colon performed four months previously for symptoms of chronic obstruction. She was readmitted to hospital with abdominal pain and vomiting, and was found to have a mass in the cæcal region. This was diagnosed as tuberculous, in spite of the absence of the usual symptoms, and proved to be such at the operation. The second case was similar, and had been operated on five years ago. There was some post-operative trouble, due to the wound breaking down and a sinus developing. This was dealt with, and the patient had resumed her work on a farm. The case was probably of bovine origin. A third case showed a rare condition, that of *tuberculosis of the thyroid gland.* The patient was a boy aged 17, who complained of hoarseness and difficulty in swallowing. The thyroid gland was obviously enlarged, indurated, nodular, and fixed, and caused pressure on the trachea. The tumour was thought to be a sarcoma, and a decompression was performed. The case, however, turned out to be a tuberculous condition affecting the trachea. The wound healed well and the patient recovered.

Prof. G. Lovell Gulland showed a case of *pellagra*, and commenced with a short description of the condition, saying that it was often caused by consumption of protein which had not the full biological value. The case dated from a trade strike, when the patient, a woman, had lived entirely on bread and margarine. She showed mental depression, a scaly rash, bronzing of exposed parts, and gastro-intestinal disturbance. She was at first put on a milk diet alone, then on as generous a diet as possible, with meat. The patient was very markedly improved, but the diet had to be watched in spring to avoid the seasonal recurrence that so often took place in this condition.

Mr. A. A. Scot Skirving showed two cases: (*a*) *Marked depressed fracture of the occipital bone and effusion of cerebro-spinal fluid under the scalp.* The condition, in a youth, was the result of a machinery accident, and had previously been shown to the Society. There had been marked effusion of cerebro-spinal fluid, which had prevented trephining and raising the bone. The patient had been under treatment for 11 months and had been tapped four times. The first time a tumblerful of cerebro-spinal fluid was removed; the last time a tablespoonful was removed. The fluid had always been perfectly clear and without a tinge of blood. There was no further necessity to tap. (*b*) *Removal of a hatpin from the second part of the duodenum.* The patient, a girl aged 3 years, was X rayed and the pin, about 2 inches in length, was seen in the stomach. On operation the pin was found to have passed on into the duodenum and to have perforated the wall, the point being embedded in the right kidney. Attempts to pass the pin back into the stomach were fruitless, and the pin was removed from the duodenum. If dealing with a similar case in future Mr. Scot Skirving said the simplest method would be to draw the pin out as far as possible, cut the pin with pliers near the head, letting this take care of itself, and pass on down the alimentary canal, and by removing the dangerous shaft of the pin an incision into the gut would be avoided.

Mr. J. N. J. Hartley showed two cases: (*a*) *Periosteal sarcoma of the head of the fibula.* The patient, a miner, aged 21, complained of a swelling in the region of the head of the left fibula. His attention had been drawn to it three months previously by a slight twinge of pain. The tumour was about the size of a tangerine orange, firm and painless. A radiogram showed osteoporosis of the head of the fibula and radiating striæ characteristic of periosteal sarcoma. A supracondylar amputation was performed. An interesting feature in this case was that the patient happened to be a school friend of a patient whom Mr. Chiene demonstrated at the same meeting, and who had a tumour almost identical in character and in the same situation. The two patients were of the same age and lived in the same district. (*b*) *Late cerebral clot after an accident.* The patient, a man aged 52, had had a cycle accident and was admitted to hospital unconscious, with concussion. Consciousness was regained on the third day, and the patient was apparently making a satisfactory recovery. On the tenth day he complained of headache, became drowsy and apathetic, and later had mild seizures, affecting the hand, face, and leg. The following morning a severe seizure spread over the whole body, he became unconscious, and his left side was completely paralysed. A right temporal exploration revealed a subdural clot extending over the cortex throughout the area exposed in the temporal fossa. Following the operation the patient improved and had recovered.

Mr. J. W. Struthers showed a case of *recurrent lipoma of the thigh.* The case was of a man aged 60. The tumour had been operated on five times and had again grown. It was suspected that the fatty tumour had undergone changes, and assumed a sarcomatous form, a very rare occurrence.

Dr. John Eason showed a case of *lead poisoning with cyanosis due to sulphæmoglobinæmia.* The patient had developed an undoubted lead poisoning after working with an acetylene burner, cutting the plates of a ship. The interesting point in the case was that in treatment cyanosis developed which proved, on spectroscopic examination, to be due to sulphæmoglobinæmia. Dr. Eason said that these cases had only been described in literature by two observers, and that the condition was much more common than was usually supposed. The diagnosis could be made by the simple procedure of diluting the blood to 1 in 20 and looking for the characteristic spectroscopic band.

Dr. W. T. Ritchie showed two cases: (*a*) *Erb's paralysis.* The patient was struck on the shoulder during the war by a falling sandbag. Recently he was admitted to hospital suffering from lead poisoning. The case showed marked lessening in circumference of the right forearm, especially in the brachio-radialis and trapezius. There was also anæsthesia in the flexor surface of the forearm. There was loss or reduction of response to faradism in the affected muscles, but no complete reaction of degeneration. (*b*) *Acromegaly.* The condition was well marked in a man of 28, who had for long been under observation. The condition was first noticed at the age of 11, and showed signs of excessive secretion of the pituitary. Recently the case had changed to one of hypopituitarism, but so far without distressing symptoms.

Mr. Pirie Watson showed two pathological specimens: (*a*) *Melanotic sarcoma of the great toe nail.* This occurred in a woman aged 49, and gave rise to secondary growths in the groin. The toe and glands were removed, and showed the characteristics of a melanotic growth. (*b*) *Omental cyst of unusual size.* Taken from a man of 68, this tumour was of very large dimensions and filled the whole abdomen. Microscopically it proved to be a malignant endothelioma, but this change had probably only supervened recently, the original growth being an omental cyst.

Dr. R. A. Fleming showed a case of *neuro-fibromatosis* occurring in a labourer aged 60. There was a wide and symmetrical distribution of tumours, involving the fifth cranial nerves and cutaneous nerves of the scalp, the cutaneous nerves of both arms and thighs, and the intercostal nerves. There were no nodules below the knees and none on the hands. The patient complained of tingling and pain along the nerves involved, but sensation to touch, heat, and cold was unaffected. Some nodules were sessile, others pedunculated.

Mr. Douglas Guthrie showed a case of *total laryngectomy.* The patient, a man aged 35, had been gassed in 1918, and complained of hoarseness ever since. Laryngoscopy this year showed the left arytenoid and ventricular band much swollen and almost occluding the larynx. Tubercle and syphilis having been excluded, tracheotomy was performed and a portion of the growth removed. The growth was found to be one of epithelioma, and at a second operation a complete excision of the larynx and the left lobe of the thyroid was performed. The patient was doing well, and had quite an audible "pharyngeal" voice.

Mr. George Chiene showed two cases: (*a*) *Elephantiasis of the left leg and scrotum.* The patient was a male aged 18. The leg had been operated on previously and had greatly improved, the scrotum was still very large, and the patient was desirous of further treatment. The origin of the condition was unknown, the patient never having been abroad. (*b*) *Sarcoma of the upper end of the fibula.* The condition first troubled the patient, a man of 21, by causing pain in the back of the leg; two months later a swelling was noticed. The patient was admitted four months from the commencement of symptoms. Sarcoma was diagnosed from X ray appearances, and the leg was amputated through the thigh. (See Mr. Hartley's case.)

Sir Norman Walker showed several cases illustrating *treatment of lupus by arc-lamps*—the "artificial sunshine" method. All cases showed marked improvement, and the minimum amount of scarring without contracture was demonstrated. A case of tuberculosis of the larynx similarly treated and showing marked improvement was described.

Mr. J. J. M. Shaw showed three cases: (*a*) *Adenocarcinoma of the pelvic colon.* The patient, a man of 71, had previously suffered from signs of subacute intestinal obstruction, followed by apparent spontaneous recovery, this two years ago, and recent onset of acute peritonitis. The growth had been removed by a two-stage operation. (*b*) *Laparotomy for acute intestinal obstruction* due to volvulus of the ascending colon in a man aged 30. (*c*) *Shrapnel wound* of the thigh sustained in a man aged 28. The wound was received in 1918, and was now causing pain. Radiographic examination showed nine and a half sewing needles in the affected part of the thigh. At the time he was wounded he was carrying a packet of needles in a case in his trouser pocket, and these had apparently been carried in with the bullet.

Dr. J. D. Comrie showed two cases: (*a*) *Disseminated sclerosis with mental changes.* Patient was a man of 33 years who had suffered from numbness of the feet for ten years, then unsteadiness and spasticity of gait, and later tremors of the hand and occasional dysuria. The plantar reflexes were extensor; the optic discs pallid. For the past two months he has been lacking in concentration, with progressive mental deterioration. (*b*) *Dementia præcox of rapid onset.* A girl, aged 19, had been rather listless for two or three weeks, when one day when at work she behaved strangely, laughing and crying without reason. Three days after this she was apprehensive, did not answer questions, smiled vacantly, had delusions of sight and hearing, and was at times katatonic.

Mr. Frank E. Jardine showed a case of *retroperitoneal hernia.* A boy, aged 13, was admitted to hospital as a case of "acute abdomen," and on examination there was found to be a tumour just under the right costal margin; this, after consideration of the symptoms and position, was diagnosed as a retroperitoneal hernia, which was confirmed at operation. Twenty-eight inches of gangrenous small intestine was found in the sac and had to be resected. Of interest in this case is that a sarcomatous tumour was found in the resected intestine, and this might have caused the hernia.

Dr. Charles McNeil showed two cases: (*a*) *Congenital pyloric stenosis.* The condition occurred in a breast-fed male infant first seen when 4 weeks old. Typical symptoms and signs were present. Stomach lavage was carried out twice daily, breast-feeding being continued. There was fairly steady improvement, with a gain of 4½ lb. in three months. Gastric peristalsis was still visible at the time of showing. (*b*) *Interlobar empyema,* with aspiration and recovery. The patient, a boy of 8 years, had dullness confined to the right axilla; he was tapped several times unsuccessfully, but eventually 3 oz. of pus was withdrawn from a needle in the mid-axilla in the third interspace. Subsequently there was steady improvement, controlled by radiograms and leucocyte counts.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

A meeting of this section was held in the Royal College of Physicians, Dublin, on Nov. 21st, Dr. F. C. Purser, the President, being in the chair.

The President read a paper on

Sequelæ of Encephalitis Lethargica,

and cases showing sequelæ of encephalitis lethargica were shown by the President, Dr. L. Abrahamson, Dr. A. R. Parsons, Dr. G. E. Nesbitt, and Dr. J. F. O'Carroll.

The President said that the most constant and, perhaps, the most distressing after-effects of encephalitis were mental. Some writers said that 95 per cent. of cases showed mental sequelæ, and many put the figure at 70 per cent. He would be inclined to adopt the lower figure. The type and severity of the initial symptoms made a great difference to the subsequent mental condition. Patients with marked lethargy and coma were far more prone to mental sequelæ than those who were sleepless or delirious, or even maniacal, in the acute stage. The age of the patient, too, made a great difference. The young, under 12, were likely to suffer most. Mental deficiency and insanity were frequently recorded as sequelæ. Most of the physical sequelæ were residua of conditions characterising the acute stage. Of these some form of ocular abnormality was the commonest. Unlike the age-incidence of mental sequelæ, children were far less liable to these residua than adults. Most cases occurred between the ages of 15 and 40. In general, physical residua, with the exception of the Parkinsonian syndrome, tended to abate as time went on. This was especially so with ocular paralyses. There was, however, much reason to fear that physical symptoms which followed an acute attack after an interval of some months, and which were not merely residua persisting from an acute attack, tended to progress rather rapidly. Involuntary movements were said to occur in 15 per cent. of cases. The form of the movements varied greatly. Some resembled Sydenham's chorea so closely that no difference could be detected between the two conditions. Hemiplegia, or less extensive paralyses showing involvement of the pyramidal tract, was not infrequently met with. Sensory residua were indefinite. Pains, lasting some weeks, and possibly attributable to lesion of a posterior nerve-root, might occur. Obesity was an unusual sequel of encephalitis, but it seemed to be the most common trophic change following an acute attack. Finally, the Parkinsonian syndrome was, next to ocular paralysis, the most common sequel of acute encephalitis. It was computed that about one quarter of acute non-fatal cases ended in this tragedy.

The post-encephalitis Parkinsonian syndrome differed from typical paralysis agitans in many particulars which, apart from the patient's history of previous illness and other residua of encephalitis which might be present, made a differential diagnosis easy. The differences were ætiological and clinical, whereas paralysis agitans proper commenced after 45, and was commoner in men than in women; the post-encephalitic condition resembling it occurred at any age, from 15 to 40 years usually, and women were at least as frequently affected as men. Further, compared with true paralysis agitans, the condition was steadily and rapidly progressive.

The President then described in detail the clinical differences between true paralysis agitans and the post-encephalitic condition, and showed a case of the latter.

Dr. Leonard Abrahamson presented two patients with sequelæ:

(*a*) A boy, aged 11, who had suffered in March, 1924, from an attack of encephalitis with abdominal myoclonus. This myoclonus was still present. It varied in intensity and the contractions were often more forcible than those noted during the acute attack. The boy showed in addition great irritability, change in disposition, insomnia, and habit of holding in his breath. (*b*) A girl, aged 19, who had experienced in April, 1924, an attack of encephalitis characterised by ocular paralysis, insomnia, and delirium. She now suffered from delusions about her food, which she thought was poisoned. She also complained of the habit of yawning frequently. At times during the yawn her mouth remained open and she was unable to finish the yawn until some time had elapsed. Another habit developed was that of frequently taking deep breaths. Insomnia was present and towards evening she showed restlessness of the left foot, which moved continuously during the night.

Dr. Abrahamson referred to the variation in the incidence of the sequelæ of encephalitis after the different outbreaks. The Parkinsonian syndrome seemed to be much commoner after the last epidemic than after previous epidemics. He pointed out that in some cases the syndrome was whittled down to one or two symptoms. He discussed the changes in character noted in children, and referred to a child who developed marked kleptomania. In his experience sequelæ occurred in about 50 per cent. of patients. In a few cases recrudescences occurred indicating that the virus could remain in the system for long periods.

Dr. J. SPEARES referred to the difficulty of diagnosing cases of encephalitis lethargica at first sight. The drug he had found most useful was luminal, starting with ½ gr. doses, and increasing to 2 gr. doses. He asked if exophthalmos had ever been seen as a result of the disease.

Dr. ALFRED R. PARSONS referred to the frequency of restlessness in cases of sequelæ of encephalitis lethargica, both nocturnal and in the day-time.

Dr. T. G. MOORHEAD referred to a case which he had recently seen, and which displayed in a striking manner the Fröhlich syndrome.

The patient, a girl, aged 23, employed at clerical work, who had suffered from a mild attack of encephalitis lethargica in January last. Since then she had been mentally dull and listless, and she now presented a typical Parkinsonian appearance. In addition, however, she showed an extraordinary adiposity, affecting the entire body, but more especially the mammary glands and the hips. There was complete amenorrhœa, and an almost complete disappearance of pubic hair.

The condition was most likely due to involvement of the pituitary gland. He also referred to the possible value of psychotherapy in the nocturnal restlessness of children. Of the various drugs used for myoclonic spasm he had found hyoscine by far the most useful, but it was necessary to give it in fairly big doses.

Dr. NESBITT drew attention to the fact that the Parkinsonian syndrome frequently occurred in the acute stage of encephalitis lethargica as well as in the later stage, and to the frequency of mental deterioration in these cases. In the case that he had shown that evening he had given doses of influenza vaccine for a considerable time without much result.

Dr. V. M. SYNGE asked what dose of hyoscine should be given. In one American journal recently he had seen a statement by some observers who had got excellent results from the use of hyoscine; some bad cases had got well enough to go back to work and others had shown a great improvement. The dose given was one-fiftieth of a grain four times daily, and in some cases one-hundredth of a grain four times daily.

The PRESIDENT, in replying, said that he thought the Parkinsonian syndrome occurred in 50 per cent. of cases, and in nearly every case the face was affected. He had not found luminal of any use, and hyoscine even in small doses had seemed to him to make the patients delirious, and although he had found that in cases of paralysis agitans it had stopped the tremor for a time, he had not given it in cases of encephalitis lethargica. He did not understand how exophthalmos could arise as a sequela of the disease. The onset of bulbar symptoms was not at all uncommon. Regarding adiposity, Duncan had mentioned the Fröhlich syndrome occurring in a boy aged about 14 who was recovering from encephalitis lethargica. He was of opinion that the Parkinsonian syndrome far more frequently came on in the acute stage of encephalitis lethargica than in the later stage.

Dr. F. S. BOURKE read a note on a case of picric acid dermatitis.

Reviews and Notices of Books.

THE NERVOUS PATIENT.

By MILLAIS CULPIN, M.D. Lond., F.R.C.S. Eng., Lecturer on Psychoneuroses to the London Hospital Medical College. London: H. K. Lewis. 1924. Pp. 305. 10*s.* 6*d.*

THE practitioner who attempts to keep pace with current developments in scientific research and modern treatment is faced with peculiar, if not insuperable, difficulties when he tries to assimilate the material dealing with that class of patient generally known as "neurotic." In the first place, the needs of the individual who has failed to adapt himself to his environment are so intimately bound up with religious, moral, and social considerations that the physician who would heal a disability of psychogenic origin must be both fitted and willing to take upon himself something of the rôle of priest and pedagogue. Moreover, the ingenuities of the neurotic's attempts to twine himself around any prop that offers are so subtle that the physician or friend who tries to help him, unless especially qualified to do so, may run less risk of disaster for both by a refusal to face the real issue and hiding behind some simple physical theory of causation.

Nevertheless, it is certain that the practitioner with common sense and a real knowledge of things as they are, is able to do an inestimable amount towards preventing and curing the minor disabilities which lie at the root of so great a percentage of our physical and social ill-health. It is now recognised that the symptom which appears in the consulting-room does not result in a direct manner from a simple cause. Treatment on a "physical" theory of causation may do no more than chop a leaf from the stem of a flowering weed, but an over-enthusiastic concentration on the psychological factors may well result in an excavation around the supposed site of the rootlets which uproots wheat as well as weeds. Only a patient and highly skilled tracing of the fibres from flower to stem and from stem to rootlets can ever remove the weed completely, and this is scarcely within the compass of the practitioner. He must usually be content with an attack at some level of the stem which will remove the flower temporarily or permanently according to the shrewdness and comprehension with which the blow is directed. An understanding of the anatomy of the plant will indubitably help his aim. For the practitioner who has little or no idea of the possible underground connexions of common symptoms, Dr. Millais Culpin's book should come as a flood of light in a dark place. He has made a courageous attempt to meet a difficult position. To convey to the non-specialist worker the gist of specialist work which is still in a tentative stage of development is always a delicate task; Dr. Culpin has succeeded in presenting, with a refreshing degree of common sense and humour, a bird's-eye view of the psychogenic possibilities behind the many physical conditions that fill our waiting-rooms, as well as some helpful chapters on the "neurotic" conditions proper, which he prefers to term the "minor psychoses."

He pursues the wise course of defining terms before embarking on their usage, and has enhanced the value of his book to the busy man by providing a copious index in chapter (1) entitled Classification and Nomenclature. Other chapter headings are as follows: (2) The Position of Psycho-Analysis; (3) Suppression and Repression: Suggestion; (4) Physical Relationships of the Minor Psychoses; (5) Hysteria; (6) Bodily Symptoms commonly called Hysterical; (7) Anxiety and Obsessional States; (8) General Principles of Diagnosis; (9) The Examination of the Patient; (10) Asthma and Allied Conditions; (11) Exophthalmic Goitre: Stammer, Epilepsy, and Hysterical Fits; (12) Gynæcological Conditions; (13) Conditions Arising After Trauma or in Relation to Occupation: Head Injuries; (14) Postural Deformities: Digestive Disturbances: The Heart Neurosis; (15) The Psychological Aspect of the Effort Syndrome. The panorama is completed by chapter (16) on "Eye Symptoms," by Mr. W. S. Inman, and chapter (17) on the "Major Psychoses" from the point of view of the practitioner, by Dr. Stanford Read, while the last two chapters deal directly and indirectly with treatment.

The section on treatment is rather vague, but the difficulties of the task which the author has set himself in his comprehensive scheme are so great that we may congratulate him on the general measure of success he has achieved. We advise all practitioners to read this handy little book.

ARTIFICIAL SUNLIGHT AND ITS THERAPEUTIC USES.

By FRANCIS HOWARD HUMPHRIS, M.D. Brux., F.R.C.P. Edin., D.M.R. & E. Camb., Consulting X Ray Physician to the American Hospital in London. London: Oxford Medical Publications. 1924. Pp. 164.

THE use of natural sunlight in the treatment of surgical tuberculosis and other diseases has obtained results so satisfactory as to stimulate a great deal of research in actinotherapy, since it would obviously be of advantage to have an adequate supply of a synthetic substitute for those rays which Nature supplies in so fitful and uncertain a manner, especially in climates such as that of the British Isles.

In the little volume under consideration Dr. Humphris covers the whole field of the history, production, and uses of artificial sunlight. His clear, concise description of the properties and production of ultra-violet light demands from the reader only a rudimentary knowledge of physics. A necessary warning is given against the little high-frequency electrode machines which not infrequently masquerade as "ultra-violet ray apparatus" in hairdressers' shops and elsewhere; ultra-violet rays will not pass through glass, wherefore any effect these bulbs may have will not be due to ultra-violet light. Dr. Humphris has done wisely in confining descriptions of apparatus to the case of a few tried models. A brief review of present knowledge concerning the mode of action of light is well up to date. Administrative technique is discussed in some detail. The dose is measured by the degree of erythema (1–4) produced; for the removal of a nævus, for instance, one must produce an erythema of the fourth degree (that is to say, a blister), whereas in tuberculosis, especially of the pulmonary variety, much smaller doses are needed. The number of diseases in which artificial sunlight appears to have been applied with benefit is very great, the list including such dissimilar complaints as hay fever, alopecia areata, and enlarged prostate. In a final chapter Dr. Humphris discusses the use of X rays as a complement to actinotherapy, and concludes that the two can safely be combined, and that in many cases the X rays definitely assist the therapeutic action of ultra-violet light.

It is to be hoped that facilities for obtaining artificial sunlight treatment will increase rapidly, especially in centres where rickets and tubercle are rife. Any medical man wanting a brief but comprehensive sketch of this subject could not do better than to make use of Dr. Humphris's excellent little book.

A TEXT-BOOK OF HISTOLOGY.

Third edition. By HARVEY ERNEST JORDAN, A.M., Ph.D., Professor of Histology and Embryology, University of Virginia. London and Philadelphia: D. Appleton and Co. 1924. Pp. 857. 25*s.*

THIS edition of Prof. Jordan's popular text-book differs little from previous ones. The book is peculiarly suitable for medical students because of the large number of illustrations it contains of preparations made from human tissue. It is disappointing, therefore, to find that the pig's liver still holds pride of place in the description of this organ, for it is difficult for the student to gain from it any true idea of the relation between the structure of the liver and its function. An even more serious blemish is the omission of any reference to Bj. Vimtrup's corroboration of Ch. Rouget's important work on the structure of capillaries. There are a few new illustrations, among them one from the heart of the "Beef." The ugly, yellow-tinted figures have no advantages over half-tones and might well be replaced.

INSULIN THERAPY.

Zur Einführung in die Insulintherapie des Diabetes Mellitus. Von H. STAUB, First Assistant der Medizinischen Klinik, Basel. Berlin: Julius Springer. 1924. Pp. 106.

ALTHOUGH the author desires that his work should be considered as only an introduction to the use of insulin, and not as a monograph, the book is in some ways the most complete which has been published. It is divided into three parts. Part I. consists solely of an excellent account, with references, of all the work which had been done in the attempt to discover insulin, and will be of use to anyone who wishes to refer to the full story. Part II. contains a good account of the discovery of insulin and of its properties, but does not add fresh information. Part III. describes the different methods of using insulin, with references to innumerable papers. The ideals of the author are to keep the blood-sugar normal, as well as the urine sugar-free, in order to allow the islands of Langerhans to have a chance of recovering their function. If no blood-sugar estimation can be made, he considers it safer to allow a little sugar to be present in the urine. The changes which take place in the various mineral constituents of the blood of a patient with diabetic coma after a large dose of insulin are very interesting. The inorganic phosphates are decreased, but the Na, K, Mg, and Ca all increased. The great influence of various infections is emphasised. The index and references are very thoroughly and carefully edited.

A TEXT-BOOK OF PHYSIOLOGY.

By H. E. ROAF, M.D., D.Sc., M.R.C.S., Professor of Physiology at the London Hospital Medical College, University of London. London: Edward Arnold and Co. 1924. Pp. 605. 25*s.*

THIS student's text-book should prove a great boon to the serious-minded students of medicine, and will doubtless become very popular among them. Physiology is treated in an original manner, and the student is gradually introduced to the more difficult parts of the subject. The book is up-to-date, well arranged, splendidly illustrated, and altogether a work for congratulation. A criticism might be made that there is, perhaps, a little too much chemistry and physical chemistry about it. But at a time when these subjects are finding such extensive applications to medical problems, it is, perhaps, just as well to include those parts of them which bear some relation to physiology. We are glad to see that the author has included some account of histology.

INDIVIDUAL PSYCHOLOGY.

By ALFRED ADLER (Vienna). Translated by P. RADIN, Ph.D., Associate Professor of Anthropology at California University. London: Kegan Paul. 1924. Pp. 352. 18*s.*

DR. Adler has claimed the title of "Individual Psychology" for his well-known theory of disturbed mental processes, though it is unlikely that the law of priority would support his claim. The theory is simple. Thwarted ambition or a sense of organic inferiority finds a spurious satisfaction through the neurotic symptom, and the "will to power," with its variant the "masculine protest" of the woman or weakly man, is made the basis of all the neuroses and some at least of the psychoses. Most psycho-pathologists agree that the neurotic symptom has not only a cause but an aim, and that the explanation of the aim is to be found in the dispositions, infantile or other, of the patient, but it is doubtful whether this aim can be usefully brought under an exclusive conception such as Adler provides. Nervous insomnia, for example, is an "arrangement" by which the patients demand that they be spared certain work and are able to force their own will upon other people (p. 165). Such simplicity is attractive till we find the same pathology applied to melancholiacs, who by their behaviour "become the centre of attention of their limited circle and are able to induce those individuals who feel obligated to help them to increased activity, to noteworthy sacrifices on their behalf, and always to make advances to them" (p. 249). When we read, too, that "A cure will take place . . . . as soon as he [the melancholiac] has enjoyed the satisfaction of having demonstrated his superiority" (p. 252), we seem to be in presence of a superficiality of observation surprising in what is described on the wrapper as "the Classic of Individual Psychology." These dicta concerning melancholia are not set out tentatively, but appear under the heading of "Individual Psychological Results obtained from a Study of Psychoses." They are in conformity with the general character of the book, which seems to have been written with an impetuosity indicated on p. 349, where the author says: "I am quite at sea as to what can be done in an age of intensified demoralisation like ours. The correct and proper thing is clearly to act immediately." This, however, is the only glimpse the author gives of any doubts he may have; the assertive manner which begins in the preface and is continued throughout will be regretted by those who believe that Adler's theory presents an aspect that exists in many neurotic disorders and must be studied in conjunction with other aspects.

COLONIC THERAPY IN THE TREATMENT OF DISEASE.

By O. BOTO SCHELLBERG. New York: American Institute of Medicine, Inc. 1923. Pp. 202.

THE nature of this book is such as to induce caution on the part of the reviewer. Its title-page gives no clue as to the qualifications of its author, its publishers are an "Institute," which at first sight appears to be connected with the more commercial aspects of our profession. At the same time, the volume is well written, well illustrated, and supplied with a brief but authoritative series of references. The book is a plea for the treatment of many diseases by a very thorough and complicated system of colonic irrigation, the results claimed being, if not extravagant, at least sufficiently startling to make the sceptical reader demand further proofs before accepting them. The author, after quoting at great length from Dr. Robert Hutchison's masterly address on the "Chronic Abdomen," claims that, in such cases, "had the cæcum been reached and treated as it should be, every symptom he describes with such exquisite precision would have disappeared." The book is interesting, but we remain unconvinced.

THERAPEUTICS.

Traité élémentaire de clinique thérapeutique. Eleventh edition. By Dr. GASTON LYON, Ancien Chef de Clinique Médicale à la Faculté de Médecine de Paris. Paris: Masson et Cie. 1924. Pp. 1406. Fr.85.

THIS is a text-book of medicine with a strong leaning to treatment. What the writer has to say about the diseases themselves is generally in small print; the treatment is in more prominent type. It is thus easy for the reader to determine whether he will study the disease as a whole or will merely cull the treatment. This edition is, as the advertisement of the book says, *entièrement refondue;* it is, as a matter of fact, well purged of old material, for it is some 400 pages shorter than the last edition, but it is quite up to date in recent work. The use of bismuth in syphilis, of insulin in diabetes, both receive good notice. That field of treatment to which anaphylaxis and the use of colloids enter, a field of which the final value is still so difficult to gauge, is well covered. The placing together in this section of treatment of shock and treatment by shock provides an instance of the subtle contrast which is so dear to the French mind. This book maintains the position it has formerly gained of being a first-class one for the practitioner who wants to keep level with the ever-advancing wave of treatment.

DISLOCATIONS AND JOINT FRACTURES.

Second edition. By FREDERICK COTTON, A.M., F.A.C.S., Visiting Surgeon to the Boston (Mass., U.S.A.) City Hospital. London and Philadelphia: W. B. Saunders Company. 1924. Pp. 745. 50*s*.

THE first edition of this sound and original work appeared in 1910. It was to be expected that this after-war edition would bear evidence of the influence on practice of the experience gained in military hospitals. It is somewhat surprising, therefore, to find how little that experience has affected civilian practice as it is represented by Dr. Cotton, who, however, takes care to tell us in his preface that his conclusions are based almost wholly on his own military hospital practice, and not from "a re-hashing of the bewildering printed and rumoured war-time reports." He is not enthusiastic in favour of the use of Thomas's splints for fractures, except as a temporary transportation measure, or combined with the Balkan frame. His experience seems to have been unfortunate, for he speaks of the occurrence of "horrid perineal sloughs" due to the use (or abuse) of this splint. Speaking of injuries of the upper extremity, of "arm traction downward, Thomas splint," he says: "I see no excuse for this arm traction thing." As regards the operative treatment of fractures, he thinks that the tendency of to-day is to minimise the use of inlay grafts, plates, and bands, and other "stunt" operative measures.

Evidently Dr. Cotton is a real master of his own methods, so that, perhaps, his results are not likely to be improved by his adoption of other methods, based on different principles. Anyway, the treatise is replete with information on the pathology and mechanism of fractures and dislocations, and with sound practical advice as to their treatment. It contains 91 pages and 192 illustrations more than the first edition.

JOURNALS.

JOURNAL OF PHYSIOLOGY. Edited by J. N. LANGLEY, Sc.D., LL.D., F.R.S. Vol. LIX., Nos. 2 and 3. Cambridge University Press. 1924. Pp. 99–258. 13*s*.—The Effect of Cerebral Anæmia upon Blood Pressure and Respiration, by Ff. Roberts. This communication deals in detail with the effects of anæmia upon the medullary functions. The experiments were all performed upon anæsthetised (urethane) rabbits and cats, with exception of two upon dogs (morphia). It was found that both the vaso-motor and cardio-inhibitory centres are directly stimulated by a slight diminution in their blood-supply. The resulting inhibition checks and sometimes annuls the rise of pressure which vascular constriction tends to produce. The respiratory centre is totally insensitive to diminution in its blood-supply until this diminution becomes extreme. Gasping is a modification of the nervous mechanism acting as a whole and is not due to the action of a separate centre. When the medulla is completely or almost completely anæmic, injection of lactic acid directly into a cerebral artery stimulates the vaso-motor centre, but is without effect upon the already paralysed respiratory centre. Hæmorrhage is not attended with any increase in breathing until a very low pressure is reached. Hyperpnœa of variable degree then occurs.—Taking up Carbon Monoxide by the Hæmoglobin of the Spleen, by A. Hanak and J. Harkavy. These observers confirm the statement of J. and H. Barcroft that on exposure of rats to an atmosphere which contained carbon monoxide the gas was rapidly taken up by the blood of the general circulation, but only slowly penetrated into the hæmoglobin of the spleen. This observation is extended to guinea-pigs and rabbits. In the case of guinea-pigs, between four and six hours may elapse before the hæmoglobin in the spleen pulp attains equilibrium with that in the blood; in the case of rabbits over two hours may elapse—a fact which suggests the almost complete occlusion of the blood-stream from the spleen, and the reduction of the rhythmic contractions to something quite nominal.—Alveolar CO_2 Pressure after Violent Exercise, by J. B. S. Haldane and J. H. Quastel. They find that the depression of the alveolar CO_2 after exercise can be used as a measure of the excess above normal of lactic acid in the blood. The amount of the latter after exercise and the rate of its removal have been determined. The rate is independent of the amount of lactic acid present, and is little affected by training or phosphate ingestion. The process of removal is vastly slower than that of the intramuscular lactic acid.—The Influence of the Blood-supply on Pancreatic Secretion, by B. P. Babkin. The pancreas is extremely sensitive to changes in the circulation provoked by stimulation of different nerves, or by substances with vaso-constrictor character or by compression of the aorta above the cœliac artery, while it continues to secrete some time after the blood pressure falls to zero. The more copious the pancreatic secretion the more difficult it is to inhibit it. The author's experiments were performed on dogs, and in chloralose he found a narcotic which itself produced a moderate secretion of pancreatic juice, and did not affect the action of hormones nor of secretory nerves. The slow continuous flow is not antagonistic to the secretory action of secretin, vagi, and pilocarpine. The section of splanchnic nerves increases the secretion provoked by chloralose, secretin, hydrochloric acid, and vagi. The stimulation of the vagi in the neck, the nerves being cut below the heart, practically does not affect the pancreatic secretion. But if a rise of blood pressure follows the stimulation the secretion is inhibited. The same relations are observed by compressing the vena cava inferior above the diaphragm. The introduction of defibrinated blood into the circulation produces a rise of blood pressure and inhibition of the pancreatic secretion. Stimulation of vagi below the heart provokes the secretion of pancreatic juice under extremely low blood pressure.—On the Location and Nature of the Action of Insulin, by J. H. Burn and H. H. Dale. The disappearance of dextrose from the blood-stream under the influence of injected insulin is now familiar, but the method of the disappearance remains obscure. Various suggestions have been made. Experiments were made on the isolated mammalian heart and on the decapitated and eviscerated cat with the view of providing additional evidence as to two relatively simple and primary points. (1) Whether the sugar which disappears under insulin is immediately oxidised or stored in some form which has hitherto escaped detection; and (2) what organs are concerned in the removal, whether by destruction or synthesis. The main results obtained are: Addition of insulin to the perfusion fluid accelerates the removal of dextrose therefrom by the isolated mammalian heart (confirming Hepburn and Latchford). The output of CO_2 by the heart is not proportionately increased, so that the extra loss of sugar is not entirely due to increased oxidation. In the decapitated and eviscerated cat, with constant infusion of dextrose, insulin produces the characteristic fall of blood-sugar. If the blood-sugar is prevented from falling by accelerating the infusion, insulin causes disappearance of sugar at many times the normal rate. The earlier stages of the insulin action are accompanied by increased consumption of oxygen, which may be pronounced, but is seldom, if ever, sufficient for the oxidation of the extra sugar lost. The respiratory quotient of such a preparation has always been unity, and has remained practically unchanged under the action of insulin. Immediate conversion of the sugar into fat or lactic acid seems to be excluded. The isolated hearts and the eviscerated preparations, from cats rendered diabetic by complete pancreatectomy, have given results in all respects similar to those of normal animals. The authors discuss the significance of these observations in relation to current theories.—The Effect of Insulin on Blood Volume, by J. B. S. Haldane and H. D. Kay. The administration of insulin to normal rabbits leads rapidly to a very appreciable rise in the blood volume. Comparative quantitative determinations in blood before and after the giving of insulin, particularly in the case of substances not equally distributed between the corpuscles and plasma, can only be accepted if this volume change is taken into account. The osmotic pressure of serum remains the same before and after the injection of insulin.—The Glomerular Control of the Kidney Blood Flow, by J. M. O'Connor. The experiments were made on rabbits anæsthetised with urethane. Owing to the anatomical structure of the kidney a secretion pressure of the urine at the head of the uriniferous tubule could not go above the pressure of the blood in the capillaries of the Malpighian tuft without cutting off the blood-supply from the kidney tubules. This would explain on a purely secretory theory the dependence of the formation of urine on the blood pressure. A similar cutting off of the blood flow through the kidney might be expected to occur when the blood pressure falls. An arrangement for determining the flow of blood for brief periods during a fall of blood pressure is described by the author.—On the Constancy of the Basal Metabolism, by Graham Lusk and E. F. Du Bois. From the records of experiments with 11 dogs the basal metabolism may be approximately determined within an error limit of ± 15 per cent. The same dog may manifest a constant level of basal metabolism extending over two years. A man between 30 and 40 years of age may show a basal metabolism during 11 years within a variation of ± 7·6 per cent.—The Effect of Variations in Blood Pressure on Pulse-Wave Velocity in the Brachial Artery in Man, by Sylvia K. Hickson and B. A. McSwiney. In normal subjects between the ages of 20 and 30, when a fall of blood pressure was noted on raising the arm to a vertical position, the lengthening of the carotid-radial interval was observed, with an appreciable slowing of the pulse-wave velocity. This postural variation in blood pressure is considerable and must be accounted for when estimating the pulse-wave velocity in arteries such as the femoral.—Vaso-Motor Centres. J. N. Langley describes his results on spinal vascular (and other autonomic) reflexes and the effect of strychnine, as determined mainly on curarised spinal cats. The animals were anæsthetised first, then either decerebrated, the vagi cut, and the cervical spinal cord severed, or they were decapitated. The great reflex rise of blood pressure obtainable after a small amount of strychnine has been injected makes it probable that in pathological cases of increased spinal excitability spinal vascular reflexes are important. No evidence was obtained that strychnine greatly increases the excitability of any autonomic nerve centre except the vaso-motor centres.—The other contributions are: The Effect of Curari and Degeneration upon the Electrical Excitability of Striated Muscle, by C. F. Watts; Blood Curves constructed with Arterial and with Venous Blood, by F. R. Fraser, G. Graham, and R. Hilton; and Renal Function in Summer Frogs and Winter Frogs, by J. de Haan and A. Bakker.

THE LANCET.

LONDON: SATURDAY, DECEMBER 6, 1924.

LICENSED HOUSES.

At the first session of the Royal Commission on Lunacy Law and Administration, reported in The Lancet of Nov. 1st, its Chairman, Mr. H. P. Macmillan, K.C., suggested that it might be necessary to reconsider the policy which since 1890 had arrested the growth of the licensed house. It may be appropriate to remind our readers of the genesis and functions of these valuable institutions. Licensed house is the official description of what is popularly known as a private asylum. Previous to the year 1774 there was no supervision or inspection of private "mad-houses" as they were then called. About that time public interest was aroused in matters pertaining to mental illness owing to the breakdown of George III. and of one of his Ministers. Private patients were then often badly housed, clothed, and fed, and many were improperly detained. It is only fair to add that conditions in the public "mad-house" were equally unsatisfactory. An Act was passed in 1774 which enforced the licensing of private asylums, hence the term—licensed house. The Act provided for the visitation of licensed premises, and made a doctor's "order" a necessary preliminary to admission. The licensing authority for the metropolitan area devolved on five Fellows of the Royal College of Physicans, appointed annually; in the provinces, the authority was the Justices of the Peace in quarter sessions. A licence was granted to any person who applied, and paid the necessary fee, and a licence could not be revoked. "Keepers" of licensed premises were obliged by the Act to send a notice of every admission to the Commissioners of the Royal College of Physicians. This Act of 1774 was the commencement of legislation concerning private hospitals for the insane, and incidentally created the first central authority in lunacy matters, the nucleus of the present Board of Control. Legislation affecting licensed houses appeared from time to time, notably in 1845, when the Lunacy Commission, with much increased powers, was constituted, and included three barristers among its paid members. In the year 1890 the Lunacy Act at present in force was passed. It resulted from the prolonged sittings of a Parliamentary Committee appointed in 1877. Among many changes, licensed houses were notably affected. By this Act no fresh licences were to be granted, and no increase of the number of patients in existing houses was to be permitted. It was, and is, permitted to transfer a licence from an old house to a new house, and provision is made for the division of a licence where a house is carried on by joint licensees. Such is a brief history of the origin and development of the licensed house to the present day. On Jan. 1st, 1923, there were 56 licensed houses in England, 19 being in the metropolitan area and 37 in the provinces. Patients in the 56 houses on the above date numbered 2206; 862 being men and 1744 women. In addition there were 149 voluntary boarders. No criminal or pauper patients are now received in licensed houses.

The restriction of licences in 1890 resulted from the conflict of opinion and evidence expressed before the Select Committee whose recommendations formed the basis of the Act. It was argued that it is undesirable for private individuals to take payment for the care of the insane, and that there must be a temptation for licensees to detain profitable patients for an unnecessary period. Further, a great many specific charges were brought against the owners of private asylums, accusing them of detaining individual cases for the sake of profit. Not a single charge was substantiated on inquiry by the Committee. It was also believed that the demand for private homes would cease with the growth of public hospitals and registered hospitals. To some extent this has been the case, as in 1890 there were 89 licensed houses in England, a figure which has fallen to 56. Yet licensed houses meet a constant public demand for private accommodation and treatment, and investigation shows that similar houses, privately owned and managed, exist in every civilised country in the world. There are houses to meet the needs and financial requirements of most sections of the English public. The licence is renewable annually; for the metropolitan houses by the Board of Control, and for the provincial houses by the justices of the county or borough in which the house is situated. The licence may be revoked, without appeal, by the Lord Chancellor on the recommendation of the Board of Control, or the justices concerned. Licensed houses are rigidly inspected, and the licensing authorities have considerable power; for example, they may direct alterations and improvements to be carried out if they consider such changes necessary for the comfort of the patients. No structural alterations may be made without the sanction of the Board of Control. Payments made by patients are notified to the Board, which is also informed of any change in the medical staff of a licensed house. Members of the Board visit the metropolitan houses six times in each year, and may arrive at any time of the day or night. The visitors to the justices, who include a medical man in their number, pay at least four visits annually to the provincial houses, while the Board of Control visits them twice in each year. These visits may be again made at any time of the day or night. In addition, licensed houses are visited by the visitors of the Lord Chancellor, who may call to see the diminishing number of patients found insane "by requisition," or to report on a patient whose affairs may be under the protection of the Master in Lunacy. The Board of Control and the visitors appointed by the justices interview every patient at their visits, and have access to the rather formidable array of official books and papers. They leave written records of each visit, and where doubt exists as to the propriety of detention in any particular case, a minute is made about the case in what is known as the patient's book. Moreover, both the Board of Control and the visitors have jurisdiction to discharge patients in licensed houses on their own authority. This frequent visitation is an undoubted advantage of the licensing system and affords protection to both public and doctors. Among other advantages of the licensed house are their small size, and the comparatively small number of cases resident at one time. The houses are generally very free from the appearance and routine of an institution, and the friends of patients enjoy complete liberty to visit at any hour, and that in strict privacy. Moreover, the relationship of the patients and their friends to the doctors is intimate, and closely resembles that existing between the family doctor and his patients in private practice.

Some measure of detention is necessary in many cases of mental illness, for social reasons, and it is this fact, coupled with the lack of insight shown in many cases into the nature of their disease that necessitates the judicial procedure known as certification, which implies the power of detention, properly protected against abuse respecting the liberty of the subject. Insanity is not the only illness in which some loss of personal liberty occurs. The infectious fevers, and many cases of tuberculosis, may be cited as examples. Unnecessary detention is as unlikely to occur in a licensed house, as in a fever hospital or sanatorium. The English public has not yet realised this fact, for it is still unable to regard insanity as an illness, requiring adequate treatment. Progress has been and is being made, as is shown by a significant change in the legal phraseology used in the various "Lunacy" Acts. In 1874 a hospital was a "mad-house," in 1890 it became an "asylum," while to-day the term "mental hospital" is in general use and is sure to find its way into future legislation. Certification is disliked by the public, and the Board of Control now allows many patients, though certifiable, to enter licensed houses as voluntary boarders, a system that might with advantage be simplified and extended. To avoid certification, a step designed for the protection of patients, there has again been a tendency of late years for certifiable patients to be received, for payment, into unlicensed premises without any formalities whatever. There can be no doubt that existing licensed houses supply a definite public need; it is also certain that the growth of the reception of patients for payment, into houses which are not open to the inspection and control of a central authority, is highly undesirable and indicates a return to a condition of affairs which all "lunacy" legislation has been framed to prevent.

◆

VALUE OF THE REFLEXES IN DIAGNOSIS.

Of the various objective methods of investigation pursued by the neurologist in the course of clinical testing, none furnishes him with more valuable information than that concerned with what are described somewhat inaccurately as the "reflexes." The detailed examination of the reflexes, using the term in its wide sense, offers the advantage of providing phenomena which can be visually observed, and some of which, further, the patient is incapable of modifying at will. Another advantage resides in the fact that their state can be determined in the course of a very few minutes, and that by scrutiny in a methodical manner from the eyes to the soles of the feet they can supply the examiner with some knowledge of the functioning of the central nervous system throughout its whole extent. No other system of examination offers such chances of diagnosis at once rapid, yet accurate, provided certain principles are borne in mind and certain precautions taken. In an address by Dr. Risien Russell, an abstract of which appears on p. 1213 of this issue, the diagnostic value of the reflexes is well brought out by clinical illustrations.

For due appreciation, however of data, many of which may be gathered even by the tyro, it is essential that the examination should be conducted with apprehension of the nature of the reflexes, and also of their topographical significance. Leaving aside certain physiological minutiæ, we may say that, in respect of what are commonly termed the tendon reflexes, the phenomenon of a muscular twitch following a smart tap on its tendon depends on the integrity of the reflex arc from the sensory end-organs in the muscle, through the dorsal or posterior roots of the cord to the ventral or anterior horn motor cells, and so by the motor roots back to the muscle. As an essential preliminary the muscle must be in a state of adequate tone or tension, which can be provided passively, in a degree, by putting it somewhat on the stretch. Since, further, the voluntary motor system can to some extent interfere with the activity of spinal reflex arcs, the examinee's attention, if need be, must be directed elsewhere than on the part that is being investigated. With limb in the optimum position, and attention diverted, a tap on the tendon will always, in health, elicit a muscular response. If the "jerk" is absent, a pathological condition exists; this, clearly, may reside in afferent mechanism, spinal centre, or motor efferent. When, therefore, to take a concrete instance, the knee-jerks cannot be elicited if the above precautions are duly observed, the investigator has reached the stage of determining the organic nature of the affection, but he cannot, without further study, localise the mischief more specifically. For example, the knee-jerks may be absent owing to lesions of the afferent limb of the spinal arc (tabes dorsalis), or of the intraspinal section (acute poliomyelitis), or of the anterior horn cells and efferent motor fibres (progressive spinal amyotrophy), or of the end-organs in muscle and muscle substance itself (myopathy). Naturally, one or other of these may suffer in combination (peripheral neuritis). To establish the loss of tendon reflexes is to make a diagnosis of the organic nature of the disease and of its topography, but nothing more. The regional spinal level of the outfall of reflectivity can be determined with ease by ranging from the scapulo-humeral reflex (fifth cervical) to the ankle-jerk (fifth lumbar, first sacral). Other reflexes can be demonstrated both above and below these levels.

The so-called cutaneous reflexes depend for their activity on a different physiological mechanism from that of the tendon-jerks, but the information they provide has similarly a double diagnostic value, topographical and differential. Thus the epigastric and abdominal cutaneous reflexes indicate the physiological condition of the reflex arcs through the spinal cord from about the sixth to the twelfth thoracic segments. The plantar cutaneous reflex shows the condition of the arcs through the lowest lumbar and upper sacral segments. But these and other cutaneous reflexes also provide a clue to the physiological state of the cortico-spinal motor mechanism that is anatomically localised in the pyramidal tracts. Unfortunately, there is a common impression to the effect that the change of the cutaneous plantar reflex from normal flexion of the great toe to extension is indicative of structural changes in the pyramidal tract; for instance, lateral sclerosis. This, however, is certainly not the case. The extensor plantar movement may occur in a limb that is in no sense paralysed to any recognisable degree; it does not conform to degrees of spasticity, for in a spastic limb there may be ankle clonus and a flexor response; it may be purely transient though genuine, as after an epileptic fit. The plantar response may change from extensor to flexor under observation and by means of certain technical procedures, as Babinski himself has shown. In spite of this variability, a plantar response in extension remains a most valuable sign of an organic as opposed to a "functional" physiological change in the normal activity of the pyramidal mechanism. When this change occurs, the movement of the great toe in response to cutaneous stimulation is shifted from one physiological group of muscles (toe flexors) to its antagonists (toe extensors), a shift of peculiar interest and significance. It might be of clinical importance to determine whether there is a similar shift in the case of the abdominal reflexes. Their abolition in organic pyramidal disorder would correspond to the absence of the plantar flexion; is there any movement in the antagonists of the recti abdominis to correspond to plantar extension? As far as we know this point has not been investigated.

There are other reflexes still—the so-called organic reflexes—whose activity requires the integrity of reflex arcs involving muscles that are not voluntary in the usual sense—arcs in which there are components belonging to the sympathetic nervous system. The value of these as aids to diagnosis is very considerable. Armed with these weapons, the clinician can reach a diagnosis with facility in any case, a diagnosis, however, that is topographical rather than pathological. This is the limitation of the method. If the bulbo-cavernosus reflex is abolished, he knows for a fact that there is impairment of function of the arc through the third sacral segment, but not whether he is dealing with tabes dorsalis, sarcomatosis of the cauda equina roots, tumour of the conus medullaris, and so on. If there is reflex iridoplegia, he cannot *ipso facto* and without further testing say whether mesencephalic neurosyphilis, mesencephalic tumour, epidemic mesencephalitis, trauma, or which of half a dozen other pathological states is responsible for the phenomenon. The tendency of the beginner to link the absence of the knee-jerks with tabes, the presence of the extensor plantar response with lateral sclerosis, the Argyll Robertson sign with syphilis, is venial but none the less regrettable. It should be the task of the teacher to inculcate principles rather than particularities. Rightly employed, the use of the reflexes aids as nothing else can in the analysis of neurological symptoms, but as the examiner taps one tendon after another, or stimulates one skin area after another, he should, in his mind's eye, envisage the corresponding segments of the nervous system, with their afferent and efferent paths: only thus will he derive that information which is in truth an "insight" into neural function.

◆

MODERN ENGLISH.

It is no easy matter for the father who has spent the laborious days and nights of his youth in the study of Addison to understand the tongue of a shingled daughter of these post-war years. In the last decade there has arisen a language, racy and descriptive, that is still partly incomprehensible to many of the older generation. It must be wholly mysterious to the strangers within our gates. This new speech, born when the principles of war-time economy seemed to extend even to words, may be ignored on the judicial bench or in the scholar's study, but it is a power in the market-place. The hour has come for the recording and explanation of this language, and with it the book—the Pocket Oxford Dictionary of Current English.[1] This little dictionary, compiled by F. G. Fowler and H. W. Fowler, well justifies the claim of its compilers to making clear the idiomatic usage of words, although there is a tendency to explain colloquial or slang expressions in equally unclassical language. For example, "to send one to Coventry" is classified into "to combine to cut him,"—possibly a foreigner would be thus justified in interpreting the phrase as meaning "a surgical consultation." As a store-house of modern terms—we hesitate to call some of them English—it is remarkably up to date, "Bradbury," "Fisher," "jazz," and "Pussyfoot" all find a place. One or two medical terms are very loosely defined—for example, "diabetes" as "a urinary disease." But the book is one of the most serviceable of small dictionaries, and a useful feature is the work of the compilers in collecting words that form a series and letting the reader know where to find them.

Annotations.

"Ne quid nimis."

REGULATIONS GOVERNING FOOD PRODUCTS.

The extensive code of regulations under the Sale of Food and Drugs Act, 1908, New Zealand Department of Health, have been considerably widened by new regulations which came into force last September. The requirements which must be complied with are set out in detail, and the conditions which cannot be permitted in connexion with most food products are prescribed with great care. The new regulations deal in particular with bakehouses and the sale of bread and pastry, places for the preparation of meat and made meat products, and for their sale in butchers' and fishmongers' shops, with the transport of meat and fish, with milk and ice-cream, and their prevention from contamination. The detailed attention paid to made-up meat products is of particular interest, since they go far beyond any powers possessed in this country, where it is generally recognised that existing powers are extremely inadequate. In New Zealand, for example, it is an offence for any person to engage in the manufacture, preparation, storage, packing, carriage, or delivery for sale of any food or of any article used or likely to be used as a food, if he is suffering from any communicable disease, or is a "carrier" of any infectious disease, or is suffering from any condition causing a discharge of pus or serum from head, neck, hands, or arms. The preparation and storage of food have to be carried out under conditions which prevent contamination by dust, damp, foul odours, or by rats, mice, or insects. All receptacles for such foods have to be kept clean. The adequate cleaning of drinking vessels and table appliances in restaurants and other premises where food or drink is sold is very fully prescribed. Detailed regulations in regard to the structure of bakehouses are enacted and as to the precautions to be observed in their usage. Places for the mincing, curing, canning, and otherwise preparing of meat (and this word is given an extended application) have to be approved and licensed by the local authority. Such premises must have smooth, impervious floors, be properly drained, internal walls with an impervious surface, roofs dust-proof and painted light colour or calcimined, construction and fittings so as to exclude, so far as possible, rats and mice and flies. Equally stringent are the requirements for butchers' and fishmongers' shops and for the storage of meat and fish in connexion therewith. The adoption of these regulations for meat and made food products in this country would mean the reconstruction of a material proportion of the buildings now in use and a very welcome revolution in practices which are now permitted, and, indeed, cannot legally be prevented.

The New Zealand regulations in regard to milk are more in line with those adopted in this country, but are more stringent. The powers for dealing with the cleanliness and freedom from contamination of ice-cream or ices are considerable and premises used for this purpose also have to be licensed. No fresh penalties are fixed in the new regulations, but presumably the penalty in Section 87 of the existing regulations will apply, and this enacts that the penalty on conviction for a breach of regulations is up to £50, and for a continuing offence not more than £2 for every day during the continuance of the offence. The detailed and explicit character of all these regulations contrast sharply with the bulk of the requirements in force in this country, which are frequently couched in vague terms. No one can read our English food enactments without being struck with what would appear to be almost deliberate looseness of phraseology. Cowsheds are to be "thoroughly cleansed from time to time as often as may be necessary," they have to be "sufficiently lighted with windows," "sufficiently ventilated" with a "sufficient number of openings" to keep the air in the dairy in a wholesome condition. "No person shall sell to the prejudice of the purchaser any article of food or any drug which is not of the nature, substance, and quality of the article demanded by such purchaser." It is worthy of serious consideration whether this loose wording should not be abandoned and replaced by a carefully thought out series of definite enactments setting out exactly what is required. Clearly defined requirements are better for the administrator, more effective for the consumer, and fairer to the trader, who knows exactly where he stands and is not at the mercy of a terminology liable to be differently interpreted in different areas.

PASTEUR.[1]

THE pious labours of Dr. Vallery-Radot in producing a complete edition of Pasteur's writings have now reached the third volume, which contains his works on vinegar and on wine. His books and papers are reproduced with the interesting original illustrations, and there are as well a number of short notes and letters to journals in which Pasteur emphasises the correctness of his views and the propriety of giving him credit for them. In these days of reckless and snippetty production, a short course of Pasteur's larger papers would do any scientific worker good, and we can imagine no better discipline, when the edition is complete in seven volumes, than to take it away to a lonely place for the long vacation and read it steadily through. It would have been helpful if the edition could have had a commentary indicating the relation of Pasteur's work to the present state of knowledge on the subjects he dealt with; such a design would certainly have been difficult to execute, but there has been so much specialisation since his day that few people can adequately appreciate the nuances of all his work.

DIABETIC COMA WITHOUT KETONURIA.

IT is usually accepted as a clinical axiom that coma with glycosuria but no ketonuria is not due to diabetes. The converse picture, however, of a comatose patient with considerable ketonuria but no glycosuria is occasionally met with in cases of diabetes. This is usually the result of some stringent measure, such as starvation, which has been adopted in order to render the patient's urine sugar-free. A few cases of diabetic coma without ketonuria have been recorded, and the October number of the *Archives of Internal Medicine* contains an account of one in which the ketonuria was insignificant.[2] Unfortunately, the tests used for the detection of ketone bodies in the urine are not given, nor is there any record of a post-mortem examination. The example quoted is that of a child, aged 9, who was admitted to hospital in a state of coma. The breath smelt strongly of acetone. The urine contained 3 per cent. of sugar and showed a faint trace of acetone, but no diacetic acid. The blood-sugar was 333 mg. per 100 c.cm., and the CO_2 combining power of the plasma, according to the method of van Slyke and Cullen, was 14·3 per cent. by volume, and so very considerably reduced. Further noteworthy points in the case were the failure of the blood-sugar to fall after the administration intravenously of 110 units of insulin (H. insulin-Lilly) within 12 hours, and the fact that the cerebro-spinal fluid, removed immediately after death, showed a very large amount of acetone as judged by the reaction to Legal's test. Death from coma occurred 15 hours after admission to hospital. Despite the large amount of acetone found in the cerebro-spinal fluid immediately after death, the blood just prior to death showed no acetone and the urine contained only a trace. The case is one of exceptional interest and its pathogenesis remains somewhat obscure.

ANÆSTHETICS IN ANIMAL OPERATIONS.

IN the course of a communication on the selection and administration of anæsthetics to animals, delivered recently to the Section of Anæsthetics of the Royal Society of Medicine, Prof. F. Hobday pointed out the curious fact that animal patients, when they have the misfortune to require surgical attention, are better protected by the laws of the land than those of human origin. By the amended Animals Anæsthetics Act, passed in 1919, a long list of operations performed in veterinary surgery were officially scheduled for compulsory anæsthetisation. For the performance of some of these a general anæsthetic is essential; with others a local anæsthetic may be used at the discretion of the operator. In the former class are included, for horses, dogs, cats, and bovines, operations for ovariotomy and laparotomy, amputations of penis, mamma, or uterus, scrotal and inguinal hernia. Moreover, horses must be given a general anæsthetic for operations for quittor, stripping the wall or sole of the hoof, poll evil, fistulous withers, extraction of permanent molar teeth, scirrhous cord, and extensive tumours; dogs and cats for castration when they are over six months old, and bovines for operations for actinomycosis and dishorning if they are over 3 months old. A local anæsthetic at least must be used for enucleation of the eyeball, umbilical hernia, and urethrotomy in all these animals, and the same ruling applies in horses to neurectomy, application of the actual cautery, docking, and trephining in dogs and cats to docking of the tail, and in bovines to rumenotomy and trephining. In regard to castration, he pointed out that the horse, ass, and mule are specially exempted, not on the ground that there is less pain when their testicles are removed, but because of the powerful and successful opposition raised at the time and backed up by influential agriculturists and owners of valuable horses. Their chief reason was that, had the Act become law as it was, the travelling gelder (who is in many districts of England the man who does most of the castrations) would have been unable to have carried on his job—partly because of his ignorance of the proper method of administration of anæsthetics and the risks to be incurred, and partly because of the difficulty (for him) of obtaining chloroform, and the added expense in time and money. Many thousands of horses are operated upon in the standing position every year. Prof. Hobday said that when done expertly the whole operation from start to finish did not exceed two minutes at most, the colt showing so little evidence of after-pain or discomfort that he usually walks right up to the manger and commences to feed at once. Here was a concrete illustration of the part played by the brain of the human in the anticipation of things—in this operation, at all events, the animal had no preliminary dread or anticipation—and here the veterinary surgeon scored over his human colleagues.

The paradox that animals are better protected from unnecessary pain than human beings is substantially true. Lawyers could not apply to inarticulate creatures the ancient maxim, *Volenti non fit injuria* or the idea that the patient's consent may be a defence to a claim for damages. On the contrary, public opinion has driven Parliament into vigorous protective measures. Vivisection is carefully restricted under a system of licences. The Protection of Animals Act of 1911 made it an offence to cause an animal to be operated upon "without due care and humanity." The Animals (Anæsthetics) Act of 1919 went further, as Prof. Hobday pointed out. The Act covers every person who operates, whether qualified or unqualified; the owner of an animal has, of course, some means of distinguishing qualified from unqualified practitioners by means of the familiar system of registration set up by the Veterinary Surgeons Acts. Parliament has never gone so far in protecting human beings from the pain of operations, though professional standards of practice in hospitals and elsewhere (which in part receive official confirmation in the working of a State service of health insurance) happily render legislation largely unnecessary. One might add another discrimination in the treatment of human beings and animals. Under the 1911 Act (replacing the Injured Animals Act of 1907) the police can, on the certificate of a veterinary surgeon, obtain the destruction of an animal which is mortally injured or so diseased or in such a physical state that it is cruel to keep it alive. We have not yet reached the point at which on formal medical certificate human beings can be similarly put out of their misery.

CATARACT IN DYSTROPHIC MYOTONIA.

Myotonia congenita or Thomsen's disease is a condition in which any attempt to use certain muscles sets up a rigidity in them so that, for example, when a patient grasps anything he is unable to relax his grasp for an appreciable time. Fifteen years ago the late Dr. F. E. Batten with Mr. H. P. Gibb published a paper[1] showing that certain cases that had been described as examples of muscular atrophy in Thomsen's disease really belonged to a distinct and independent category. Two facts were subsequently discovered—one, that the disease which had been known to be, as a rule, familial, always occurs in some members of a number of families of the same child-rank in relation to a common ancestor; the other, that one of the extra-muscular symptoms that go along with the disease is a form of cataract. In the dystrophic generation some members who are not otherwise affected may have premature cataract alone. Affected members may also have it, and—a very remarkable circumstance—even in other generations of the same stock where there is no member affected with the muscular symptoms cataract is not uncommon. If we go back for two generations before the affected one the cataract is generally of the ordinary senile type. In the generation immediately preceding the one with the affected stock it is generally presenile and in the affected generation always. The subject has recently been investigated by Dr. W. J. Adie, who, in the November number of the *British Journal of Ophthalmology*, suggests that many of the cases which have been described as tetany cataract are examples of this disease. In 1912 J. Hoffmann put forward the theory that all the symptoms, both muscular and ocular, were the result of a general intoxication, due to a disturbance in the organs of internal secretion or of the central nervous mechanisms that control them. Another suggestion is that the toxin that causes the cataract is the result of the breaking down of the muscular tissue. According to Dr. Adie, cases of dystrophia myotonica have been reported from all over the world, their numbers now running into hundreds. He has himself found records of 66 cases in which cataract was a symptom occurring along with the muscular symptoms. In 41 cases he found records of cataract occurring in the affected stock, either in the same or in previous generations, without the accompaniment of muscular symptoms. This evidence, supporting as it does that of many other authorities, makes it clear that a connexion exists between cataract and a congenital constitution, one of whose manifestations is a peculiar affection of the muscular system. According to all observers the cataract begins in the posterior cortex. According to B. Fleischer[2] it ripens fairly quickly to a total soft cataract with a small nucleus at about the same time in both eyes. It is highly probable that the connexion that many of these cases have with a general disease has hitherto passed unnoticed. It would therefore be well if whenever an ophthalmic surgeon comes across a case of presenile cataract he would make careful inquiries with a view of eliciting a possible connexion with muscular cramps and muscular atrophy, either in the patient or in the relatives, near or remote.

BISMUTH TREATMENT OF SYPHILIS.

Dr. H. de T. Shivers,[1] chief of the United States Public Health Service for the Treatment of Genito-urinary Diseases, records his observations on 60 syphilitic patients treated by bismuth, nearly all of whom were in the tertiary stage. The vast majority showed improvement, and with the exception of three cases the reactions following the administration of the drug were rare and not severe. Potassium bismuth tartrate with butyn was the preparation exclusively used; 0·1 g. was the dose given in ordinary cases once a week, and 0·2 g. in more severe cases. A total of 2 g. was administered, and after an interval of four weeks a second course comprising the same number of injections was given. If a third series of 20 injections was needed the rest interval was longer. A few patients with early secondary syphilis who resisted arsenic responded to bismuth. The effect of the drug on tertiary lesions was rapid and in some cases more favourable than that due to arsenic. In neurosyphilis relief of meningeal headache was as prompt as after salvarsan. In cerebral syphilis bismuth was effective in controlling convulsions and in relieving insomnia and nervousness, while in tabes it was more successful in checking the lightning pains than arsenic. Its action on the Wassermann reaction was fairly satisfactory, as 16 patients, or 26·6 per cent., gave a negative reaction after a total dosage of 4 g. None of the patients developed stomatitis, probably because the drug was never given more often than twice a week, and also because they received careful instructions in the proper care of mouth and teeth. Bluish-grey lines on the gums were seen in a few patients receiving 0·2 g. a week. Only three patients developed severe reactions which consisted in severe chill, high fever, nausea and vomiting, and a feeling of marked oppression in the chest, but the occurrence of such reactions is a warning that the administration of bismuth is not without some danger to the patient, and that the same care should be exercised in its use as in the cases of salvarsan preparations.

SCHISTOSOMIASIS IN NATAL.

Urinary schistosomiasis, or bilharziasis, is quite the most common form of parasitic infection in man in Natal. Although the prevalence of this disease has been recognised since 1864, when Dr. John Harley first detected the characteristic terminal-spined eggs in a case of hæmaturia in that colony, its importance from a public health standpoint has once more been emphasised by Dr. C. G. Kay Sharp, Medical Inspector of Schools, Natal, in an article he has contributed on this subject to the *South African Medical Record* of Oct. 25th. The infection appears not to be confined to the native or Asiatic, but is also prevalent in European school-children. The coastal area of the province is heavily infected, especially the river estuaries, where swamps and lagoons form in which the molluscs which act as intermediaries abound. The exact proportion of natives infected with this parasite is difficult to ascertain, since a large number never seek European medical advice, but the incidence amongst women is known not to be high, as they are not permitted to bathe in public places, and so do not risk the danger of infection. Dr. Kay Sharp has collected records of 300 cases of urinary schistosomiasis in school-children, the proportion being 40 out of 300 in an Indian school at Stanger, while in nine European schools 64 cases of hæmaturia were discovered, and it is estimated that in Durban 2·4 per cent. of the male school population is afflicted in this manner. In young persons the hæmaturia is most marked after exertion, especially on a hot day. Symptoms may include headache, digestive disturbances, and giddiness, results of toxic absorption, pyrexia, urticaria, abdominal pain, pulmonary symptoms, and emaciation. The tingling, or itching, of the skin, due to penetration of the cercariæ through the integument, is a fairly common symptom after bathing. Attacks of appendicular colic, due to deposition of the eggs in the appendix, have also been observed. Dr. Kay Sharp's recommendations regarding the prevention of the spread of this form of schistosomiasis are various. Firstly, it should be made compulsorily notifiable to the health authorities, while indigent sufferers should be given free treatment. Every effort should, therefore, be made to persuade sufferers, by means of propaganda and education, to seek treatment. All rivers, spruits, and lagoons which are known to be infected should be advertised to the public, and warning notices erected at public bathing-places. The keeping of domestic ducks, which feed on freshwater snails in infected waters, should be enthusiastically encouraged. It is stated that small minnows, known as "millions," are useful also in this respect, as they are said to feed upon the cercariæ. Certain wild birds, such as ducks, egrets, herons, flamingoes, ibis, and storks which also feed on snails, should be vigorously protected. It has even been suggested that the importation of a bird, known as the Australian mudlark, might be advisable.

INTRA-UTERINE OVARIAN GRAFTS.

The operation of transposing the ovary with its neurovascular pedicle into the uterus is intended to preserve menstruation with the possibility of pregnancy in women after double salpingectomy. In a recent communication[1] read to the Académie de Médecine, Paris, Prof. T. Tuffier brought forward considerable clinical and experimental evidence in favour of this procedure. In his experience the efficiency of the operation is undoubted, although the results are not constant. Since July, 1922, he has performed the operation on 38 occasions; after excluding seven cases operated upon since May, 1924, it was found that nearly 90 per cent. of the remainder had regular periods, sometimes more profuse than formerly and occasionally preceded by painful symptoms. Pregnancy with normal labour was recorded in one instance. There were no deaths, but late hysterectomy was necessitated on two occasions, including one for intestinal obstruction not related to the ovarian transposition; also, one laparotomy was performed for a post-operative hæmorrhagic extravasation. Two other patients ran a temperature of 38° C., which was accompanied by a painful sero-purulent vaginal discharge, and in one a gangrenous ovary was extruded. These accidents were ascribed to imperfections inseparable from the evolution of a new technique, of which a detailed account, illustrated by 14 well-printed plates, appeared recently.[2] The operation includes resection of both tubes, mobilisation of the intact ovary, and its fixation into a previously dilated uterus; the uterine wound is afterwards brought together by three or four interrupted catgut sutures followed by a second series of linen Lembert serous sutures close together. It is necessary to be sure that the ovarian pedicle is not constricted and that peritonealisation is perfect. No definite conclusion can, of course, be drawn from such a small number of cases, nor has sufficient time elapsed to judge of the after-results, but the incidence even of one pregnancy among his 38 cases is of great interest. On the other hand, the preservation of menstruation which may be more profuse than formerly and may be preceded by painful symptoms is not likely to be welcomed by the patient unless she is keenly desirous of embracing even a slender chance of another pregnancy.

A CASE OF LEISHMANIASIS IN RIGA.

Dr. R. Adelheim reports,[3] from the Pasteur Institute of Riga (Latvia), a very carefully investigated case of leishmaniasis in a child of 5. He observes that tropical diseases are always slipping into Europe now and must be kept well in mind by doctors who see puzzling cases. The child's illness had come on insidiously four months before with fever, loss of weight, and anæmia. Dr. Berkholz, who saw her on July 30th, 1921, noted that the spleen was greatly enlarged and hard, and that the liver was slightly enlarged too. A blood examination showed red blood corpuscles, 2,290,000; white blood corpuscles, 4100; hæmoglobin, 40; differential counts taken about that time gave, per cent., lymphocytes, mostly small, 77; neutrophiles, 20 (3 immature, 12 band-form, and 5 segmented nuclei); large mononuclears, 2; no eosinophiles; myelocytes, 1. No malaria parasites could be found, but there were many leishmania parasites in a smear of blood obtained by splenic puncture. Various remedies were tried, but no improvement was observed until antimony tartrate was given intravenously about the middle of September, when she began to pick up rapidly. The red count went up quickly to 4,000,000, the white to 7400, and, per cent. in differential count, there were: lymphocytes, 50; neutrophiles, 40 (2 immature, 26 band form, and 12 segmented nuclei); large mononuclears, 8; myelocytes, 2. By Christmas the child was well, thanks to the antimony. The father was a high Russian official, three months returned from Tashkent, Russian Turkestan, where the family had lived comfortably, and the little girl had hardly been at all in touch with native children. It appeared, however, that they had brought back with them a German dog, in bad health, and always getting thinner. No leishmania were seen in a smear of its blood either, but, at the post-mortem, the spleen was found much enlarged, the liver slightly, there were characteristic abdominal hæmorrhages, and many parasites in the spleen smear. With the spleen juice Dr. Adelheim injected white mice subcutaneously, and some of them contracted the disease. The author is of opinion that the disease is not carried by a parasite such as a flea, but most likely by the stools. This question might well be the subject of a research by a medical officer in the Mediterranean, where this disease is tolerably frequent.

THE MEDICAL DIRECTORY, 1925.

The eighty-first annual issue of the Medical Directory[1] appears a month in advance of its date, while many of the corrections which it contains are quite recent. A sign of the times is the omission of the Dental Section, after an association of 57 years' standing, owing to the fact that the publishers propose to issue shortly a separate directory of graduates and licentiates in dental surgery, intended to fill the want felt by many people for an inexpensive self-contained dental directory. The space so saved seems likely to be utilised in other ways, for on pages lxxxvi. and lxxxvii. will be found the first instalment of a list of members of the British Association of Certificated Masseurs, which is to be increased in a later edition. There is no doubt that further additions of names and addresses of other groups of medical helps would be useful to practitioners. Other features of the Directory remain unchanged, except that in the list of titles conferred upon members of the medical profession appears for the first time the name of a woman. The numerical summary records a total of 49,351 names, showing a substantial increase in every section except that of the Services, where the 1922 figure of 3475 names looks unlikely to be again reached. In round numbers, the additions in London are 250, in the Provinces 500, in Wales 80, in Scotland 550, in Ireland 200, abroad 300. The section of British Spas and Climatic Health Resorts, fresh and informing though it is, loses prestige from the omission of the corresponding section on foreign resorts which used to appear. The only misprint we have noticed is in the title of a well-known medical official, but it is unfortuate that the names of Ministers of the Crown should lready be out of date. It might be better, in a work f reference of this kind, to avoid including the names f those whom political fortune may displace. In its resent issue the Directory continues to fill a worthy ôle.

UNDER the Dangerous Drugs Acts the Home ecretary has made regulations, dated Nov. 20th, a) prohibiting, except under licence, the diversion f raw opium or dangerous drugs passing in transit hrough a port in the United Kingdom to a destinaion other than that to which they were authorised o be consigned from the country of export; and (b) nodifying, in the case of prescriptions for dangerous rugs which are given on the official National Health nsurance form, the requirements to be observed efore the prescription may be dispensed.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XCIX.

THE TREATMENT OF VERTIGO.

VERTIGO or giddiness is a peculiar disturbance of quilibrium in which the patient experiences a feeling f movement either in himself or in surrounding objects. n severe cases there may be staggering or reeling, or he patient may even fall to the ground.

Equilibrium is maintained by the properly adjusted onic contractions of certain muscles. It is controlled y a centre situated in the cerebellum. From the skin, nuscles, joints, eyes, and labyrinth afferent impulses ass to the cerebellum and are there transformed into fferent impulses which travel through the superior erebellar peduncles to the red nuclei. From the red uclei impulses pass to the lower motor neurones, so hat the contractions necessary to maintain equilirium are ensured. Although afferent impulses then re sent from many parts, the most important are those rom the labyrinth, and thus it is that vertigo is so requently associated with aural disease. For this eason it is convenient to classify cases of vertigo nto (1) those associated with aural disease, (2) those n which no aural disease is discoverable.

Vertigo Associated with Aural Disease.

This group comprises a large number of cases. In ll the vertigo is due to disturbance in the labyrinth; n many it is the result of an irritative lesion in the xternal or middle ear—for example, wax in the xternal auditory canal, or suppuration in the middle ar. In others, usually the more severe, it is the esult of an actual non-suppurative destructive lesion n the internal ear, the exact nature of which is not usually ascertainable. Very severe vertigo is also aused by sudden extension of a suppurative process rom the middle to the internal ear, the treatment of which calls for immediate surgical interference. It s therefore necessary, in all cases of vertigo associated with deafness, to obtain the opinion of an aural surgeon hat the precise condition of the ear may be determined. In a number of cases the vertigo is paroxysmal and is associated with vomiting in addition to deafness; this triad of symptoms—namely, vertigo, deafness with tinnitus, and vomiting—constitutes Ménière's syndrome. In these cases the vertigo may be so sudden and so severe as to cause the patient to fall as if felled, though in Ménière's syndrome there is never any loss of consciousness, an important distinction from petit mal and fainting.

Where the vertigo is associated with a lesion in the external ear, such as a plug of wax in the external auditory canal or a severe inflammatory lesion or with suppuration in the middle ear, the treatment is directed to the local condition.

The treatment of vertigo the result of a non-suppurative lesion in the labyrinth demands attention: (*a*) during an attack, (*b*) between the attack as a preventive measure. During the attack the patient is put to bed with the head slightly raised, hot-water bottles are put to the feet, and calomel, gr. v., administered. As a preventive measure between the attacks the patient should be warned to avoid sudden turning movements of the head, undue exertion, and the watching of quickly passing objects as experienced by looking out of the window whilst travelling in an express train. Sometimes even gazing at moving pictures may incite an attack. Constipation should be prevented, and tobacco and alcohol used only in moderation. The most efficacious drugs are iodides, bromides, strychnine, and quinine. In any particular case it is difficult to say which of these is likely to be most successful, though in those with a neurotic temperament I think bromides are indicated, whilst strychnine is perhaps the most beneficial in debilitated individuals. On the whole, however, I believe that quinine in small doses with or without bromides will be found to be the most valuable drug in warding off attacks of vertigo of this class. A useful prescription is:—

℞	Quininæ sulph.	gr. ½
	Ac. hydrobrom. dil.	♏xv.
	Tinct. aurantii	♏xx.
	Aq. ad	℥ss.

℥ss. night and morning.

Vertigo Unassociated with Aural Disease.

Vertigo in these cases may be the result of disturbance of afferent impulses from sources other than the labyrinth. This is probably the explanation of vertigo occurring when a person walks from a hard on to a soft surface, resulting in a disturbance of afferent impulses received by the cerebellum from the deep structures—e.g., joints. Again, vertigo may be due to ocular disturbances, generally the result of paralyses of external eye muscles associated with diplopia, but in a few cases in which there is no paralysis and in which dizziness with headache occurs after prolonged use of the eyes, it would appear that the dizziness is due to some error of refraction, for cases occur where examination of the eyes has revealed some error of refraction, and the wearing of suitable glasses has benefited the condition. Neurotic vertigo is fairly common, such, for example, as vertigo occurring in certain individuals when they get into a crowd or into a large open space, or when they find themselves in a confined place, such as a theatre. Fear, no doubt, plays an important part in these cases. Patients with neurotic vertigo rarely fall. This type is best treated on the general lines laid down for the treatment of neurasthenia aided by some sedative drug such as bromide of potassium or sodium and valerian. Vertigo occurring with epilepsy and migraine calls for no special treatment outside that employed for the relief of the nervous condition with which it is associated. In migraine the eyes must be carefully examined for some error of refraction, and any error found corrected with suitable glasses. In many cases no other treatment is necessary. In others considerable benefit may be derived by taking pil. quininæ, gr. i., twice a day, combined with a diet restricted in animal food and strict instructions to the patient to eat sparingly. Where the attacks of migraine occur at fairly regular intervals I believe that, in addition to the above treatment, luminal, gr. ii., each night for a few nights before an attack is expected is beneficial.

Vertigo is also associated with certain organic diseases of the central nervous system, but I know of no special treatment which affords relief in these cases. It occurs notably in cerebellar disease, when it may be central in origin or due, as in cases of cerebral tumour, to a general increase in the intracranial pressure. It may also be met with in disseminated sclerosis and in general paralysis of the insane. Giddiness is a symptom commonly complained of in all forms of anæmia, and does not call for any treatment other than that employed for the relief of the anæmia. Another common cause of vertigo is some gastro-intestinal disturbance, such as dyspepsia and constipation. It is probably due to the sudden discharge into the blood-stream of poisons manufactured in the alimentary tract and is relieved by giving calomel, gr. v., followed by a saline purge. Toxic vertigo due to alcohol and tobacco is well recognised and is relieved by removing the cause.

Disturbance of Intracranial Circulation.

Perhaps the commonest cause of vertigo is some disturbance in the intracranial circulation resulting in either hyperæmia or anæmia of the brain. Cerebral hyperæmia is probably the explanation of the giddiness which occurs associated with hot flushes at the menopause, though in most instances where vertigo is due to disturbances in the cerebral circulation it is the result of anæmia of the brain consequent upon sclerosis of the cerebral arteries. Associated with the vertigo in these cases there is usually a high blood pressure, but in a few cases, owing to myocardial degeneration, the blood pressure is below normal. In either case, when the vertigo is severe it is a grave omen. In the one type it is often the forerunner of a stroke and in the other of sudden cardiac failure. The treatment is somewhat different in the two types of cases.

(*a*) *Where the blood pressure is high* the patient should avoid all strenuous mental and physical effort; if possible he should retire from active business. He should be warned against stooping or sudden alterations in position, but gentle exercise should be allowed. The diet should be restricted as regards meat, and two or three days a week should be meatless. Any meat that he takes is better grilled or cut from a joint rather than stewed. Beef tea, gravies, and meat extracts should be forbidden. The bowels should be kept relaxed but not purged. Suitable aperients are phenolphthalein, 2–4 gr., phenolax, 1 or 2 wafers; in certain cases a small dose of a saline aperient taken each morning is most beneficial. The object should be to produce two relaxed evacuations daily rather than an occasional purging. Alcohol and tobacco must be used only in moderation. Iodide, either as potassium iodide or in the form of iodalbin, iodicin, or collosol iodine, is, I believe, the most useful drug in this type of case. It should be given in moderate doses over a long period. In some severe cases I have seen benefit derived from taking iodalbin, gr. v., three times a day and erythrol tetranitrate, gr. ½, night and morning.

(*b*) *Where the blood pressure is low* exercise must be more curtailed, but the same rigid precautions are not necessary as regards the diet; in fact, it is better to allow meat to be taken daily. These cases are more difficult to relieve than are those with a high blood pressure. Medicinal measures are disappointing, though some patients are benefited by giving iodide in some form in moderate doses three times a day and a digitalin granule, 1/600 gr. (Nativelle), night and morning; others obtain considerable relief by taking a Gélineau's dragée night and morning.

MEDICINE AND THE LAW.

STOPES *v.* SUTHERLAND: HOUSE OF LORDS' DECISION.

THE judgment delivered in the House of Lords in the appeal by Dr. Marie Stopes against the decision of the Court of Appeal in her action for libel against Dr. H. G. Sutherland was referred to in THE LANCET of Nov. 29th, p. 1137, in connexion with the question, not raised in the action, of providing teaching on contraception in medical schools. In the recent appeal the House of Lords were asked to review, and did in fact reverse by a majority, the decision of the Court of Appeal, the question at issue being in substance what ought to be the judgment that in law should follow from two answers given by the jury at the trial before the Lord Chief Justice, those two questions having been put to them. Two other questions were answered by the jury to the effect that the words published were defamatory and that the damages, if any, should be £100, but the questions and answers referred to the House of Lords were the second and third—viz.: (2) Were the words true in substance and in fact? Yes. And (3) were they fair comment? No. Upon these findings, which to many will seem inconsistent, the Lord Chief Justice entered judgment for the defendant, Dr. Sutherland. The Court of Appeal by a majority held the plaintiff, Dr. Stopes, to be entitled to judgment for damages and costs. The House of Lords, in judgments of which the principal are summarised below, held that the Lord Chief Justice had decided rightly and restored his judgment.

The Lord Chancellor, Lord Cave, after stating the facts and pointing out that the House was not concerned with the ethics of contraception, defined the points to be determined as being (1) the meaning and effect of the verdict, and (2) whether there should be a new trial. The jury's answers (2) and (3), given above, appeared at first sight to be inconsistent. The plea that the words complained of were true in substance and in fact ("justification") meant that all those words were true and covered not only the bare statements of fact contained in the alleged libel, but also "any imputation which the words in their context may be taken to convey" (Collins, Master of the Rolls, in Digby *v.* *Financial News* [1907] 1 K.B. 509). It had been held to follow from this that if a verdict was found in a defendant's favour on a plea of justification there was no room for any discussion of the plea of "fair comment." "The plea of fair comment does not arise if the plea of justification is made good" (Lord Loreburn in Dakhyl *v.* Labouchere [1908] 2 K.B. 325 n.). Although, however, this might be the ordinary rule, Lord Cave agreed with the Court of Appeal that its application in the present case was difficult. The Lord Chief Justice in his summing-up undoubtedly had drawn a distinction between fact and opinion, and while he had carefully instructed the jury to deal with the "real sting of the matter" and the "pith and marrow" of the statements of the defendant, he appeared to have invited them to deal under the heading of fair comment with those portions of the matter complained of that were expressions of opinion upon facts alleged and proved. He (Lord Cave) would deal with the verdict on that assumption.

The alleged libel might be divided into three parts: (1) That the plaintiff was taking advantage of the ignorance of the poor to submit them to experiments. As to this Dr. Sutherland had explained his meaning to be that the poor were made the subject, not of surgical experiments at Dr. Stopes's clinic, but of a social experiment which was contrary to the laws of nature. This was a question of fact, and the jury had found the statement to be true. (2) It was complained that the defendant alleged that working women were instructed in a method of contraception, which had been described by Prof. Louise McIlroy as the most harmful method of which she had had experience. As to this the jury were instructed that they must not only find that Prof. McIlroy had declared this method (the use of the check pessary) to be harmful and dangerous, but must further find that it was so in fact. This also was a statement of fact, and was found to be true. The jury had before them evidence on which they could find that methods of contraception recommended by the plaintiff might cause injury, particularly with regard to the use of the "gold pin," which several witnesses had said was calculated to produce abortion. (3) The defendants in effect said that the literature published by the defendant was no less obscene than that for which Charles Bradlaugh was prosecuted, and that it infringed the criminal law. This also was found to be true by the jury, and passages in the plaintiff's books were evidence that could be considered as justifying the finding. This point again was treated as a question of fact at the trial.

The Lord Chancellor asked, if the above charges had been found to be true, what remained in the alleged libel to which the description of "unfair comment" might be taken as having been applied by the jury. In the Court of Appeal two statements had been referred to as matters of opinion upon which might arise a question of "unfair comment": (1) That regarding "the decent instincts of the poor," and (2) the expression "monstrous campaign." Possibly there might be added the expression as to the offence of Charles Bradlaugh being a less serious one. Was there, then, evidence or material upon which a reasonable jury could find that these expressions of opinion, or any of them, constituted unfair comment, the other charges having been found true in substance and in fact? This was a question for the Court, which had to determine whether the document under consideration was capable of being a libel (Collins, Master of the Rolls, in McGuire *v. Western Morning News* (L.R. 2 K.B., p. 111)). He did not think that there was any such evidence. The first appeared to him to express the opinion of the writer as to the practice of birth control itself, and not as to the plaintiff's methods of advocating it. He did not see how the reflections on the plaintiff could be said to be unfair having regard to the facts found to be true. "Monstrous" was undoubtedly comment, but if, as the jury had found, the defendant was justified in saying that the campaign was carried out by circulating obscene and criminal matter, the epithet "monstrous" could add nothing to the libel, nor could the comparison with the case of Bradlaugh. The expressions were mere shadows of the substantive charge of which no separate justification was required. His Lordship referred to Edwards *v.* Bell (1 Bing. 403), Morrison *v.* Harmer (3 Bing. N.C. 759), and Cooper *v.* Lawson (8 A. and E. 746). It appeared to him that the case under consideration fell within those decisions, that the expressions complained of as comment added nothing to the substantive charge, and that consequently there was no evidence on which a rational verdict of unfair comment could be founded. Consequently the judgment of the Court of Appeal could not stand, and he was further of opinion that there was no good ground for ordering a fresh trial on the ground of misdirection. The order of the Court of Appeal would be discharged, and the judgment of the Lord Chief Justice restored with costs above and below.

Lord Finlay, in a concurring judgment, said that it seemed to him to be impossible to hold that the bounds of fair comment were exceeded by an expression of honest opinion to the effect that the practices advocated by the plaintiff were revolting to the healthy instinct of human nature. The aversion on this ground from such methods was old and widespread. Reference had been made in argument to passages in the plaintiff's books, which were of such a nature that they had not been read aloud. The books had a wide circulation, and in his opinion were calculated to have a deplorable effect upon the young of both sexes. It would, in his Lordship's view, be absurd to say that the epithet "monstrous" exceeded the bounds of fair criticism, or that it was not fair comment to imply that such passages, as had been pointed out, might be held to aggravate the criminality of obscene libel. Lord Finlay regarded it as unfortunate that the plaintiff, a doctor of philosophy, should apply to herself the title of doctor in connexion with her clinic, as to do so must lead many of those attending the clinic to think that the person at the head of it was a Doctor of Medicine.

Lord Shaw of Dunfermline and Lord Carson delivered judgments, in which they concurred with the Lord Chancellor and Lord Finlay in holding that the appeal of the defendant should succeed.

Lord Wrenbury, in delivering a dissenting judgment, referred to the interest taken by many thoughtful persons in the question of birth control during the last 15 or 20 years, and to the work of the National Birth-rate Commission, which sat from 1913 to 1916, and after being reconstituted took evidence in 1918 on questions which included matters dealt with in the plaintiff's books. The plaintiff herself was a member of the Commission, and when the Birth Control Committee of the Commission met on Nov. 7th of the present year, Lord Wrenbury observed, Lord Dawson of Penn was one of those who gave evidence. He mentioned this in order to emphasise the grave importance of the question of birth control, to parents and prospective parents, of personal importance to those working among the poor of public importance, and of national importance to those who had at heart the welfare of the nation. There were what some thought to be grave reasons affecting individual cases for the employment of birth control. Others thought that in no case ought such control to be exercised. He expressed no opinion as to which were right, but strong feelings were roused by the controversy, and hard language might well be used without causing surprise. It was for the jury to decide whether such language, if used, was libellous. The jury had all the evidence, including the plaintiff's books, before them, and the question was for them to decide. Expressing no opinion himself on the matter, he could not say that 12 reasonable jurors might not decide that the expressions used as to "experiment on the poor," and as to a "monstrous" campaign amounting to a crime were not justifiable, especially as the plaintiff had been admitted by her opponents to be bona fide seeking to assist her poorer sisters. In his opinion the majority of the Court of Appeal were right in upholding the verdict upon the answer to the third question, and in giving judgment for the plaintiff in accordance with that verdict. The jury had found in the plaintiff's favour on the question of fair comment and assessed damages, and if their findings were not to have effect, then in his view it followed that there had been, by reason of misdirection, no proper trial of the issue of fair comment, and this would entitle the plaintiff to a new trial.

The judgment of the Court of Appeal was accordingly reversed. Since then we are informed that Dr. Stopes has presented a petition to the Lord Chancellor.

THE MISUSE OF PRESCRIPTIONS.

At a recent inquest near Llanelly, upon the body of a married woman, 43 years of age, the jury returned a verdict that "the death was due to the taking by misadventure of an overdose of medicine containing strychnine, associated with the low physical condition of the deceased due to the morphine, in accordance with the testimony of Dr. Owen Williams. We are of the opinion that no criminal neglect is due to anyone, but that greater care should be exercised in future in labelling medicine containing poison." The story leading up to the death of the deceased, which was the occasion for the above finding, was contained principally in the evidence of a druggist, who stated that for several years he had supplied the deceased with bottles of medicine in extraordinary quantities, for which frequently she used to send her children or the children of neighbours. A great deal of this medicine was ostensibly under a prescription. The prescription provided for 2 drachms of morphia, but the druggist, recognising the craving of his customer for this drug, reduced the morphia to 1½ drachms, and finally, when she asked that the medicine should be supplied in larger quantities and in greater strength, gave her no morphia in two out of the three bottlesful that she was consuming daily. At a later period she was having three bottles a week of the medicine containing morphia, her purchases being made up to three bottles a day with tonics and purgatives. Among the tonics she used was one containing strychnine, of the danger of which he warned her, but there was no warning written on the bottle last sold to her before her death. Medical evidence based upon the post-mortem examination was given to the effect that death was due to strychnine and not to morphia.

The law does not forbid unlimited repetition in the making up of a prescription, and probably such a limit in all cases would be resented by the public, however desirable it may appear to the medical profession. It would be easier to impose and to enforce limits to the use of any prescription containing certain specified drugs. Probably nothing, except, possibly, the efforts of relatives, would have hindered the woman in this case from drugging herself.

AN ERROR IN DISPENSING.

An action of an unusual character was tried recently by Lord Darling and a special jury. The plaintiffs were Mr. R. R. Boyd and his young son, Geoffrey R. Boyd, and the defendants, Messrs. Savory and Moore, Limited, were sued on the ground of their alleged negligence in dispensing a prescription for the use of the son. In defence they denied negligence, and pleaded that they had acted reasonably in reading the prescription in question, and further that the plaintiff, Geoffrey Boyd, had suffered no damage through their act. Geoffrey Boyd, 22 years of age, was from the age of 11 years subject to epileptic fits, and in 1922 Dr. Henry Head gave for his use a prescription for medicine to contain 1½ gr. of luminal sodium. The defendants made up this prescription at various dates from May, 1922, to March, 1923, and misreading the amount of luminal sodium ordered, always compounded it with half a grain, instead of a grain and a half. The plaintiffs alleged that through this error the youth's recovery was delayed at a time when he was expecting to go into his father's business, and damages were claimed accordingly. Dr. Head, called on behalf of the plaintiffs, described luminal sodium as a "tricky drug," and in answer to a question from Lord Darling said that it was impossible to tell whether a grain and a half would have had any influence in the patient's favour. He explained the circumstance in which he had prescribed it, and in reply to Mr. Eastham, K.C., counsel for the defendants, stated that he was unable to say that the omission of a grain of luminal sodium every night for ten months, the period of the prescription, had had any material effect on the course or progress of the epilepsy. As far as he could say the omission had done no harm.

After reference by Mr. Eastham to the "rather misleading" character of the writing of the prescription, Dr. C. Hinds Howell gave evidence in support of the view that the absence of a grain of luminal sodium had made no difference to the epilepsy, and said that half a grain was a common amount to prescribe. Sir William Willcox agreed, and added that he had first dealt with luminal sodium as a hypnotic in lectures in 1913. It was first used for epilepsy at some time during the war, but was very often ineffective with regard to epilepsy in any dose. In reply to questions raised by the jury, Sir William Willcox said that there was no recognised cure for epilepsy, and that continued use in large doses of such a drug as luminal sodium might cause mental degeneration. He should not attribute an increase in the plaintiff's fits to the diminution in the luminal sodium administered to him.

The jury were unable to arrive at an agreement as to their verdict and were discharged. Mr. Justice Darling gave judgment for the defendants with costs, on the ground that there had been no evidence to go before the jury of any damage resulting from the alleged negligence, even if there had been negligence. A stay of execution was granted in view of a possible appeal.

ROYAL SOCIETY OF MEDICINE.

THE ANNUAL DINNER.

THE annual dinner of the Royal Society of Medicine was held on Nov. 26th at the Hotel Victoria, London, Sir StClair Thomson, the President, presiding over an assembly of some 400 persons. Since their election to the Society women have, of course, been present at the annual dinner, but necessarily only in small numbers. The innovation on this occasion was the permission to members to bring guests of either sex, and the result was to make of the gathering a large series of small dinners flanked by one long, high table.

After the loyal toasts, Sir Auckland Geddes proposed the Prosperity of the Royal Society of Medicine, laying stress on the fact that the great work of the Society, though done directly for the profession, resulted in enormous benefit to the public. The general facilities of the Society, and especially the library, enabled a large mass of doctors to keep abreast, either by the work of the sections or by the consultation of references, with their science. In speaking of the Transactions of the Society, he pointed out that, while there were 4000 members on the roll, their communications to the proceedings were included in 2000 pages. He raised considerable laughter by wondering when the House of Commons would have rules whereby the average in "Hansard" was only half a page per M.P.

Sir StClair Thomson, replying for the toast, pointed out that the motto of the Society was "Life is not worth living if it is not lived well," and commenced his speech by a versicle regretting that speeches had to be made, for, he said :—

"I like the talk that comes between
The pottage and the peaches ;
But hail with a dejected mien
The speeches."

After a criticism of the inarticulateness of Englishmen he paid an eloquent tribute to the prevision of the late Sir Andrew Clark and the devoted service of Sir John MacAlister who, he said, was absent upon his doctor's strict directions. "The ideal," he said, "to which we have attained was foreshadowed by Sir Andrew Clark when he held in 1892–93 the position of President. His wise imagination bodied forth the objects of our existence in the words : 'A Royal Academy of Medicine is calculated to bring together for their common help all the investigators in the various departments of medicine.' Sir Andrew Clark died a few months after, but 15 years had to pass before what he had imagined attained a local habitation and a name. And thereby hangs a regret. For he, who wielded the English language so gracefully, had suggested the title of 'Academy' for our body, just as Mr. James Berry at this table in 1922, when speaking as President of the Medical Society, said that, being a collection of societies, the title of 'Academy' was much more appropriate. That may come yet. But it is only a family matter whether we call ourselves a society or an academy. This amalgamation, shadowed orth by Sir Andrew Clark, was the endorsement of a scheme at which another man had toiled for years; not a medical man, mark you, but one who loved us as a brother and in return we all wear him in our heart's core, aye, in our heart of hearts. He had worked at it for more than five years before Sir Andrew died; he toiled on it for 15 more years before it was accomplished; he has continued another 17 years to better what he had already bettered. He has served this Society for 37 years. It has been his life's work, and he has given his life to it. It is only his doctor's strict orders which prevent our perpetual secretary, Sir John MacAlister, from being with us to-night."

The President then acknowledged the valuable services of the hon. librarians, Mr. Walter Spencer and Sir Humphry Rolleston, and the hon. treasurers, Mr. C. H. Fagge and Dr. Farquhar Buzzard, adding that a great debt was due to Dr. Arnold Chaplin for undertaking to catalogue, mount, and index the Society's fine collection of over 4000 prints. In thanking Sir Auckland Geddes for the terms in which the toast of the evening had been given, Sir StClair Thomson said: "You, Sir, in coming here to-night and in proposing the health of our Society, have, I assure you, added to your large troops of friends in the two hemispheres. You need not have taken the chairmanship of the Food Inquiry to gain the shortest way to our hearts. We all know and are proud of your record. We have not forgotten that you went through the South African War as a lieutenant in the Highland Light Infantry; that as recently as 1908 you took your M.D. with the gold medal at Edinburgh, and that little more than 10 years ago you were making models in the dissecting room of McGill University in Montreal. Then came your last crowded ten years of glorious devotion to your country—Member of Parliament, Director of Recruiting, Minister of National Service, Minister of Reconstruction, President of the Local Government Board, President of the Board of Trade, Brigadier-General, gassed in France, Principal of McGill University, and His Britannic Majesty's Ambassador to the United States. And you are not yet 46! In France the highest honour that can be given a man is to put on record that he has deserved well of his country. Anyone who visits the Hôtel de Ville in Paris will see that in the last ten years only two names have been added to the lists on the walls—those of Clemenceau and Poincaré. Underneath them are written the simple and thrilling words, 'Ils ont bien mérité de la patrie.' You have deserved well of your country; your profession is proud of you; this society is most deeply grateful to you."

Sir George Blacker proposed the Health of the Guests in a deliberately light vein, and referring to the possession by women of the Parliamentary franchise, said that Sir Douglas Hogg's electoral campaign had led to the unheard-of situation in Harley-street and Wimpole-street that doctors were seen abroad with their wives. Until that occasion it seemed that the medical inhabitants of those streets could never appear with their wives, some of the men being too busy, and the others being engaged in pretending that they were too busy.

Sir Douglas Hogg, the Attorney-General, replied, and pointed out that his profession and that of medicine were the two strictest trade-unions in the country, and had this in common, that their unionism was non-political, while the difference in status was indicated by the fact that doctors, it seemed, could be proceeded against for lapses of conduct, when lawyers enjoyed an immunity owing to the fact that they had taken care to make the laws. Speaking as Member for Marylebone, "a most important medical constituency," he viewed with admiration the amount of gratuitous work which was done by the medical profession, and he wished that the poorer people of the country could receive the same service from lawyers, inasmuch as, during his tenure of office as Attorney-General, he had seen many cases in which free legal assistance was needed almost as badly as free medical assistance.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Measles and Whooping-cough in Edinburgh.

OWING to an outbreak of measles and whooping-cough in Edinburgh a letter was circulated to local practitioners by the medical officer of health. In this notification is invited of first cases occurring in any family and payment of notification has been approved by the town council. The letter points out that the object of the notification is to inform the public health department of the existence of cases of measles or whooping-cough, so that home visitation by qualified fever nurses may be carried out. If, however, a practitioner does not consider it necessary or desirable for visits to be paid by a nurse, a statement to this effect is to be added to the notification form. Where home environment is found to be faulty or likely to be prejudicial to the health of those affected, removal to hospital will be undertaken. The letter terminates with an appeal for coöperation in order to reduce the death-rate from these diseases, especially among children under 5 years of age. Since the adoption of this scheme of notification, 105 cases of measles and 113 cases of whooping-cough have come under notice. As long as the epidemic was confined to the Leith area, where apparently it had origin, one nurse was able to overtake the necessary visits, but with the extension of the diseases to Edinburgh, it was essential for a second nurse to be employed. Up to the present the results from home visiting have not been very encouraging, and in cases where removal to hospital has been considered advisable a certain amount of opposition from parents has been encountered. In cases of scarlet fever or diphtheria no protests have been offered to the removal of children to hospital, but in the case of measles and whooping-cough, parents, not realising the dangers of these conditions, are often reluctant to allow a child to go to hospital, considering home treatment quite sufficient. An endeavour has been made to surmount this difficulty by means of propaganda. A statement is made to the press by the medical officer of health in which he points out that measles and whooping-cough in young children cause a greater number of deaths than diphtheria and scarlet fever, though the two latter are looked upon as much more serious maladies.

Edinburgh Royal Infirmary.

Some interesting details with regard to the financial position of the Edinburgh Royal Infirmary were given on Nov. 26th at the sixth annual meeting of the League of Subscribers, which was held at the Oddfellows' Hall, Forrest-road, under the presidency of Mr. James Campbell. A report submitted by Mr. Russell Paton, the organising secretary, showed that the revenue obtained by systematic collections at public works and places of business in the city and country districts amounted to £20,904, or an increase of nearly £560 over subscriptions obtained last year from similar sources. From reliable estimates it would seem that the individual membership of the League is now about 73,300 for Greater Edinburgh and 23,200 for country districts, an increase of some 2500 over last year's figures. During the year 152 new groups have been added to the League. The workers' contributions from all sources have been estimated at £40,000 per year, which shows how well the work of the institution is appreciated by the working classes. The total expenditure of the infirmary for the past year, it was stated, amounted to £127,500, or an increase of £7700 compared with the previous year. Against this, however, must be placed £78,900 in legacies. An interesting item in the report was the fact that the salaries of the senior nurses had been substantially increased. Reference was made to the offer of £30,000 by the Rockefeller Trust for the erection of a clinical laboratory in the infirmary grounds. It has been decided to accept the offer, provided the laboratory becomes the absolute property of the infirmary.

At the 243rd anniversary dinner of the Edinburgh Merchant Company held in the Company's Hall it was announced that the Company's Education Board had resolved to give the management of the Royal Infirmary an opportunity of acquiring the buildings and site of George Watson's College. The members of the Company must be congratulated on their generosity, for the offer involves the finding of a new site for the school. Throughout its existence of 243 years the Company has had a reputation for its public spirit.

Aberdeen Medico-Chirurgical Society.

The annual business meeting of the Society was held on Nov. 20th, when the following office-bearers were elected: President: Dr. Peter Howie; Vice-President: Dr. James Crombie; Secretary: Dr. H. Edgar Smith; Treasurer: Dr. George Rose; Editor of Transactions: Mr. G. H. Colt; Librarian: Dr. W. Clark Souter; Recording Secretary: Dr. H. Ross Souper; Assistant Secretary: Dr. Robert Richards; Members of Council: Dr. A. G. Anderson, Dr. G. M. Duncan, Mr. F. K. Smith, and Dr. H. Ross Souper.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Belfast: The Robert Campbell Oration.

THE second Robert Campbell Memorial Oration was delivered in the Medical Institute, Belfast, on Nov. 20th, by Dr. Thomas Houston. Dr. J. Singleton Darling, President of the Ulster Medical Society, occupied the chair, and there was a large attendance of members of the profession from Belfast and Ulster. Dr. Houston, after paying a personal tribute to the late Mr. Campbell, then gave his address on the subject of

Addison's Anæmia.

He first called attention to Thomas Addison's original account of the disease and showed how this masterpiece of clinical observation would be handed down to all future students of medicine. Since Addison's time certain additions to our clinical knowledge of the disease had been made. Hunter deserved the credit of originating the intensive study of the true nature of this remarkable form of anæmia. His researches led him to the view that Addison's anæmia was a specific infective hæmolytic disease, and that the source of the infection was the alimentary canal and the seat of the blood destruction the portal circulation. Hurst had added a predisposing factor to this almost accepted theory of Hunter's, emphasising the view that the achlorhydria which always preceded the onset of the disease was generally congenital and predisposed to the specific infection of the alimentary canal by streptococci or other organisms. The older theories of Cohnheim and Ehrlich were still adhered to by some able writers on the subject. More work required to be done before any of these theories could be generally accepted. Mr. H. Gilford had called attention (THE LANCET, Jan. 13th, 1923, p. 64) to his view that Addison's anæmia might be due to a premature senescence of the blood-forming organs. He pointed out that one of the main objections to such a view was the supposed rarity of the disease in old age. It was questionable, however, whether the disease was so rare in old age as the literature of the subject would lead us to suppose. In old age the patient was not considered a fit subject for clinical investigation and every ailment was ascribed to senile decay. Dr. Houston had seen quite a number of cases of Addison's anæmia in patients over 70 years, and believed that many more would be found if they were looked for. This view would also fit in with certain recent work on blood destruction by Louisa Ashby, who came to the conclusion that the blood destruction that occurred in the disease might be explained by a speeding-up of the physiological processes of blood destruction and the embryonic or senile character of the blood might predispose to this increased destruction.

Dr. Houston then briefly discussed the treatment of the disease by (1) arsenic, (2) hydrochloric acid, (3) blood transfusion, and (4) splenectomy.

Irish Free State: The Local Government Bill.

A debate and division of some interest took place recently in the Dail during the discussion of the Local Government Bill. Section 17 of the Bill proposes to give the Minister power to establish consultative councils for giving him advice in connexion with such matters affecting health as might be specified in an Order. At the same time the Bill proposes to abolish the Irish Public Health Council, which has the power, of its own initiative, to offer advice to the Minister on all matters concerning health. Mr. Johnson, leader of the Labour party, moved the deletion of Section 17 and proposed the substitution of a new section to establish a Public Health Council to advise the Minister. The council would consist of eight persons, representing boards of health, appointed by the Minister after consultation with such councils; four persons representing councils or county boroughs; three doctors, two having diplomas in sanitary science; one dentist, one veterinary surgeon, two nurses, and two midwives. The new section further provided that the Public Health Council should meet at least twice a year, and that payments might be made by the Minister out of moneys provided by the Oireachtas to members of the Public Health Council, and to committees thereof, to such extent as might be sanctioned by the Minister for Finance in respect of travelling expenses, subsistence allowance, and compensation for loss of time.

Mr. Johnson's views were supported by Sir James Craig, the medical member for Dublin University, and by several members of the Labour Party and of the Farmers' Party. It was opposed by a "Business Member" on the ground of expense. The Minister opposed the amendment, and after an irrelevant attack on the medical profession, for which he subsequently apologised, gave as his reason that the existence of a council such as was suggested by Mr. Johnson would lead to friction with his department, and that he preferred to be advised by the Dail rather than by such a council. In the subsequent division the amendment was defeated by 30 votes to 27, the Minister having no support outside his own party except that of the two "Business Members." The narrowness of the Government majority is a great encouragement to those who believe that a council with originative power would initiate a strong health policy.

Dublin Milk.

Under the auspices of the Royal Dublin Society, Dr. J. W. Bigger, professor of bacteriology in Dublin University, recently delivered a lecture on milk. He was chiefly concerned with the condition of the Dublin milk-supply in its relation to health. He stated that Dublin milk, on an average, contained 600,000 bacteria per cubic centimetre in winter and 4,000,000 in summer. Tubercle bacilli of the bovine type were found to be present in 8 per cent. of the milk bought and sold in Dublin. Tuberculosis was very prevalent in cows in Dublin, 1 out of every 12 was capable of communicating the disease. He alluded to experiments carried out under the old and newly devised methods of taking milk from the cows. Consequent on the precautions taken under the new methods they had produced milk that remained sweet for seven and a half days on an average, or three times as long as the milk obtained under the old conditions. Forty-eight per cent. of the milk sold in Dublin might, he said, be condemned as unfit for human food, and it was essential for the health of the community that the public should demand clean milk. He considered the present price of milk excessive. Dealers were able to supply hospitals and other institutions at contract prices enormously below the figure charged the public. Whether it was good or bad milk, clean or dirty, the same price was charged in Dublin. The law took cognisance of those extracting fats from milk, but not of those selling milk impregnated with bacteria, which was actually poisoning the child life of the city, and he pleaded that some public interest in this question of milk should be aroused. If that could be done, he concluded, it would be possible to obtain a satisfactory milk-supply in Dublin.

Tercentenary of the Founder of the Royal College of Physicians of Ireland.

On Nov. 26th the Royal College of Physicians of Ireland celebrated the 300th anniversary of the birth of its founder, John Stearne, in the presence of the Governor-General of Ireland, of the President and Fellows of the College, of the President and Council of the Royal College of Surgeons, who attended with their mace, and of a distinguished company of visitors. The Registrar of the College, Dr. T. P. C. Kirkpatrick, delivered an oration in honour of Stearne. John Stearne, of English descent, was born in Co. Meath in 1624, and entered Trinity College, Dublin, in 1639. His course of study was disturbed two years later by the outbreak of the Great Rebellion, and he betook himself to Cambridge, where he entered at Sidney Sussex College. After some ten years in England, spent mostly at Cambridge, though he also worked at Oxford, Stearne returned to Dublin as a Fellow of Trinity College. He had studied medicine at Cambridge, and on his return to Dublin he began practice as a physician; while in the College he held, in addition to his Fellowship, the chairs of medicine and of Hebrew. A few years later he was entrusted by the Board of the College with the duty of establishing and presiding over a confraternity of physicians, to be housed in Trinity Hall, a building outside the College, but only a few yards from the gate. Twelve years later this society received from Charles II. a charter as a College of Physicians, Stearne being named as first president. He died three years later at the age of 45. Stearne does not appear to have written any works on medicine, his few publications being concerned rather with philosophy and theology. A vote of thanks to Dr. Kirkpatrick was proposed by the Provost of Trinity College, and seconded by Dr. J. O'Carroll, a past-President of the College of Physicians.

BERLIN.

(From our own Correspondent.)

The Hadwen Case from the German Standpoint.

Considered from the standpoint of German legislation and German views the recent Hadwen case[1] presents many points of interest. In Germany a course of treatment such as that adopted by Dr. Hadwen in a case of diphtheria would, it seems, be regarded as malpractice—Kunstfehler. In a recent number of the *Aerztliche Sachverständige-Zeitung*, the journal of medical experts, malpractice is described as a bodily injury, or a prejudice to the health of a patient produced by the neglect of generally adopted principles of medical science. If a medical man, for example, has deliberately withheld antitoxin treatment this would be, according to the law, a "vorsätzliche Körperverletzung"—deliberate injury to health—a crime punishable with imprisonment up to three years; if the patient lost a limb, or an eye, or became totally unable to work, the medical man would be liable to imprisonment up to five years; if the patient died the minimum penalty would be five to ten years' penal servitude. The consent of the patient does not protect the medical man from prosecution, although he would not be liable to pay damages to the patient. The use of methods which have not received the sanction of the profession as a whole would be criminal where such methods caused injury or death to a patient, but is, of course, not punishable where the outcome has been of benefit to the patient. It is worthy of note that this law does not apply to the medical profession alone; the above rules are part of the general legislation on injuries, whoever may have caused them. In the forthcoming reform of criminal law it is intended to make special provisions in this matter with regard to the medical profession. Prosecution of medical men is indeed very rare, whilst actions for damages on behalf of patients occur rather frequently.

Deterioration of the Air in Berlin.

Berlin enjoyed, before the war, a relatively good and pure air, compared with that of other great cities, but now this has changed altogether, as has been ascertained by careful experiments made in the Hygienic Institute of the University on behalf of the city authorities. The chief cause of the impurity of the air is, as explained by the director of the Hygienic Institute, that the cleaning of the streets has been reduced for reasons of economy, so that more dust develops, notwithstanding the fact that fewer horses are now on the streets; also, the great increase of motor traffic has led to the presence of a greater quantity of petrol fumes in the air; this is the more noxious as motor-car proprietors are inclined to use, for economic reasons, petrol of an inferior quality, and out-of-date carburetters which develop more vapour than the modern ones. A by-law prohibiting the use of obsolete carburetters and of petrol of inferior quality is being considered.

Proposed Reform of the Lunacy Laws.

Proposals made some time ago to unify the legislation with regard to lunacy, which varies in the different German States, have not met with the approval of experts. A new Bill has therefore been drafted for Prussia alone, where the present lunacy laws are somewhat obsolete. The principles of the proposed Bill were recently described by an official of the Ministry for Public Welfare which deals with lunacy laws. It is proposed that to obtain the admission of an insane person to an asylum an application to the police should be required. The application must be made by the family of the patient; in place of the family the Poor-law authority, and in cases of soldiers the military authority, may apply for the admission of the patient. The application must be based on a medical certificate setting forth the nature and the history of the disease and containing a reference to the patient's heredity. The police would be obliged to give their consent when the district medical officer has certified that the admission is necessary for the protection of the patient himself, of his property, and of other persons to whom he may become dangerous. In urgent cases it is proposed that every medical man may certify the immediate necessity of the admission of a patient, and the consent of the family may even be dispensed with. If a patient has been admitted to a private asylum, he must appear personally, within 48 hours, before the district medical officer. Law courts will also be entitled to order that a person should be admitted to an asylum for a period not exceeding six weeks for observation, to ascertain whether or not the person is responsible for his acts. A person may be admitted to an ayslum at his own request, but in that case he must appear at once before the district medical officer and may be kept in the asylum only with the consent and on a certificate of that officer. A central board for the control of the asylums under the Ministry of Public Welfare, and local boards for each province, consisting of a Government officer of health, an alienist, and a layman with experience in social matters, are to be established. Every asylum must be inspected at least once a year without previous notice; the members of the inspecting board must have the opportunity to speak to every patient and they are also entitled to look into the case-books. It is pointed out by the Ministry of Public Welfare that the preliminary of police sanction for admission to an asylum should put an end to wrongful detention. A well-known alienist has protested in the press against the Bill on the ground that the necessity of approaching the police would induce some families to abstain as long as possible from having an insane relative admitted to an asylum. To carry out the work outlined in the proposed Bill the number of police officers would have to be increased, an anomalous proceeding at a time when the number of asylum medical officers has been reduced for reasons of economy.

Broadcasting of Lectures on Hygiene.

Broadcasting has been used in Berlin for lectures on hygienic subjects. The lectures concerned first-aid in accidents and in hydrophobia (a disease which has become rather frequent), the hygiene of dwellings and of travelling, and tuberculosis. It was proposed also to deal with the prophylaxis of venereal diseases, but that proved inadvisable because the lectures would also be heard by children.

The Services.

ROYAL ARMY MEDICAL COLLEGE.

Maj. J. A. Manifold, R.A.M.C., relinquishes his appt. as assistant professor.

ROYAL ARMY MEDICAL CORPS.

Capts. R. B. Price and H. F. Panton (Bt. Maj.) to be Majs.

Capt. J. Biggam is restd. to the estabt.

TERRITORIAL ARMY.

Supernumerary for service with the O.T.C.—Lt. F. R. Sandford, from the Gen. List, T.A., to be Lt. for service with the Medical Unit of the London University O.T.C.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. E. T. H. Lea, from Active List, to be Maj.

ROYAL AIR FORCE.

Flying Officer C. V. D. Rose is promoted to the rank of Flight Lt.

DEATHS IN THE SERVICES.

Maj. Robert Carlyle Carlyle, who, with two Syrian medical officers, was among the killed in the Sudan mutiny on Nov. 27th, graduated in medicine and surgery at the University of Edinburgh in 1911. The following year he entered the Royal Army Medical Corps as a lieutenant and was appointed captain in 1915. Two years later he was attached to the Egyptian Army.

Royal Commission on National Health Insurance.—The eighth meeting of the Commission was held at the Home Office, Whitehall, on Nov. 27th, Sir Andrew Duncan in the chair. The examination of the representatives of the Hearts of Oak Benefit Society, Mr. Hezekiah Dudley, chairman of the Executive Council, and Mr. J. P. Lewis, C.A., secretary, was continued. Various questions relating to the deposit contributors, the insurance of married women, the scheme of penalties for arrears, the additional benefits, the application of surpluses were dealt with. The Commission announce that the oral evidence given at the meeting of Nov. 13th, 1924, is now on sale in proof form (1*s.* 6*d.*) at H.M. Stationery Office, Adastral House, Kingsway, London, W.C. It should be understood that this and the similar proofs issued at weekly intervals are subject to correction, and that the evidence as finally published on behalf of the Commission will be the only authoritative record of their proceedings.

INFECTIOUS DISEASES ABROAD.

The following general summary is compiled from the monthly Epidemiological Reports published by the Health Section of the League of Nations, supplemented, when possible, by more recent information from other sources.

Plague.—In India this year the curve of plague mortality dropped to its lowest point in the last week of July, which is a few weeks later than usual. The curve has since risen steadily to an average of about 500 deaths per week for the country as a whole. In the week ending Nov. 15th no death from the disease was notified in the ports of Bombay, Calcutta, Karachi, and Madras, but there were three in Rangoon. As regards other parts of the world, the following is a list of countries or localities in which the disease has recently occurred:—Europe: Crete (August), Greece, Naples, Paris. Asia: Beyrout, Ceylon, Dutch East Indies, Baghdad, Jaffa, Bangkok, Singapore. Africa: Algeria (August), Canary Islands, Gold Coast, Madagascar, Mauritius, Nigeria (Lagos), Uganda, Union of South Africa. America: Ecuador, Los Angeles (outbreak of pneumonic type with 31 deaths reported up to Nov. 13th).

Cholera.—In India during August the reported cholera cases averaged about 8050 per week and deaths 4850. For the week ending Sept. 27th the figures were 4251 cases and 2422 deaths. Very few cases have recently been reported from other parts of the world.

Yellow Fever.—Sporadic cases continue to be notified from the Gold Coast and from ports of Mexico and other countries in Central America. It is estimated that at San Salvador there were 60 cases between June and September.

Typhus.—The typhus situation in Russia and Eastern Europe at present is believed to be more favourable than in any year since the war, but as regards most of the countries June is the last month for which full statistics are available. In Poland only 246 cases were notified during August; Esthonia, Latvia, Lithuania, Czecho-Slovakia, Jugo-Slavia, Roumania, and Bulgaria were almost or quite free from the disease. The most recent notifications from other countries are: Algeria, week ended Oct. 31st, 4 cases; Chile, week ended Oct. 13th, 20 cases (at Talcahuano); Egypt, week ended Nov. 11th, 14 cases, of which 2 at Cairo; Italy, week ended Sept. 28th, 1 case at Sesto al Reghena; Malay States, week ended Nov. 21st, 1 case; Portugal, week ended Oct. 18th, 1 case at Oporto; Syria, week ended Sept. 30th, 1 case at Aleppo; Turkey, week ended Nov. 8th, 1 case at Constantinople.

Small-pox.—In general the small-pox situation abroad at present is decidedly favourable. Northern Europe (including Scotland and Ireland), the Baltic Republics, and Central Europe as far south as Roumania are almost or quite free from the disease, and it is declining in many other areas where it was prevalent. The following figures indicate the recent incidence in some important countries: France, week ended Oct. 10th, 1 case at Paris; Italy, week ended Oct. 19th, 4 cases; Spain, week ended Nov. 2nd, 5 cases at Madrid; Portugal, week ended Nov. 15th, 1 death at Oporto; Switzerland, week ended Oct. 25th, 2 cases in the Berne Canton, 1 in the Lucerne Canton; Greece, month of September, 4 cases; Algeria, week ended Nov. 10th, 26 cases; Canada, 3 cases at Vancouver, week ended Oct. 11th; United States, 47 cases in California State, week ended Sept. 27th; 7 cases in Oregon and Washington States week ended Oct. 11th.

Enteric Fever.—In many countries enteric fever appears to have been more prevalent this summer than last. The increased summer incidence was particularly marked in the Baltic region (Sweden, Finland, Esthonia, and Latvia). In Denmark, however, only 55 cases were notified during August, as compared with 191 during the same month last year.

In Germany, 1967 cases were notified in the four weeks ending Sept. 6th, as compared with 1680 during the preceding four weeks, and in Italy 1159 cases during the week ending August 23rd, as compared with 373 cases during the previous week.

Scarlet Fever and Diphtheria.—In Germany and the Netherlands the incidence of these diseases during September was somewhat higher than last year. The following are a few recent statistics of deaths in certain cities: Paris, Nov. 1st to 10th, 3 deaths from diphtheria; Amsterdam, week ended Oct. 11th, 1 death from scarlet fever; Berlin, week ended Sept. 27th, 2 deaths from scarlet fever, 3 from diphtheria; Breslau, Cologne, and Frankfort-on-Main, week ended Sept. 27th, 1 death from scarlet fever in each; Leipzig, week ended Oct. 25th, 3 deaths from diphtheria; Munich, week ended Sept. 27th, 2 deaths from diphtheria; Budapest, week ended Sept. 20th, 1 death from scarlet fever, 1 from diphtheria; Warsaw, week ended Nov. 8th, 10 deaths from scarlet fever, 2 from diphtheria.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal statistics of four of our largest inland cities for 1923:—

Name of city.	Estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Birmingham.	946,400	20·1	10·8	1·06	1·15	2·2	31	72	3·5
Sheffield ..	524,200	19·4	11·5	1·03	1·19	2·5	39	90	4·0
Leeds	469,900	18·5	12·7	1·35	1·22	2·5	42	89	5·2
Bradford ..	290,800	18·2	13·7	1·02	1·29	3·0	36	78	4·9

Birmingham.

Dr. John Robertson says that during 1923 the general health of the people of Birmingham reached a higher standard than ever before. For further improvements he pins his faith to a more intensive educational campaign, to which the school, the health nurse, the press, special lectures, and pamphlets must contribute their quota. He thinks the late war has left many people with a somewhat unbalanced mentality. The whims of neurasthenics are too sympathetically dealt with and the question of sex looms too largely in the lives of many city dwellers. While he is convinced that much lies with the individual there is still much to be done by the local authority. He instances the need for better arranged houses in pleasant environment and the total abolition of all the courtyard houses in Birmingham; also the need for greater facilities for outdoor recreation; and, thirdly, the need for permanent allotments. Birmingham, like some other places, had a small outbreak of enteric fever caused by the paratyphoid B bacillus, for which no cause could be assigned. Arrangements have now been made with all the nursing societies in Birmingham to supply a visiting nurse for cases of measles, whooping-cough, and pneumonia on the request of the public health department. For this purpose a grant of 10s. per case is made to the nursing society. Unemployment and the housing conditions militate against the prevention of tuberculosis, but, on the other hand, the relief given to distressed persons has been very effective.

The report of the chief tuberculosis officer, Dr. G. B. Dixon, shows that 60 per cent. of all the notified cases of pulmonary tuberculosis were examined during the year. Dental treatment is provided for the patients and artificial dentures on advantageous terms. Dr. Dixon gives a table showing the present condition of patients treated in previous years. Of the patients whose sputum contained tubercle bacilli, 22·3 per cent. of those treated in 1913 are at work regularly, while 26·4 per cent. of those treated in 1919 are working regularly. It is found that in only a limited percentage of cases is it possible to arrive at a correct diagnosis after one or two examinations in the consulting room. For this reason the observation beds at Yardley-road Sanatorium have been found most useful. During 1923 311 cases, about one-fifth of all the sanatorium patients, were admitted to these observation beds for a period varying from two to four weeks. In 41 per cent. a positive diagnosis was the result and in 59 per cent. a negative. Dr. Robertson gives a table showing the percentage of samples of mixed milk found to be tuberculous during the last 17 years. The percentage for the whole period is 8·7, while the percentage for 1923 was 8·2. There is thus no indication that the operation of the milk clauses contributes to the lessening of bovine tuberculosis or tuberculosis of the udder. Cows with tuberculous udders are not necessarily the most infectious cases, so it is not to be expected that the milk clauses would do anything more than remove dangerous milk at an earlier period than if no action were taken. Mr. Brennan De Vine, the veterinary inspector, reports in a useful manner on the Birmingham effort to secure tubercle-free herds. There are now 18 herds in the scheme, 13 of which are breeding herds. All the herds are tested half-yearly. The results show that there are generally some reactors at the half-yearly testing, even in the breeding herds, though six of the breeding herds had no reactors. Cows purchased subject to passing the test are returned to the vendors if they fail to pass. Cows which give a doubtful reaction are isolated and re-tested a month or six weeks later. The number of cows tested for the first time during 1923 under the scheme was 311, and of these 67, or 21·5 per cent., failed to pass. Mr. De Vine's report indicates many of the difficulties to be encountered in securing and maintaining tubercle-free herds. Except in the case of breeding herds the outlook does not appear to be hopeful. Dr. Robertson is enthusiastically in favour of adequate pasteurisation. He thinks that even the inadequate methods of pasteurisation and sterilisation, which have been the rule in Birmingham for some time past, have had their effect in producing a low death-rate from non-pulmonary tuberculosis. A number of firms are now engaged in installing up-to-date pasteurisation plant to comply with the new regulations.

The Carnegie Infant Welfare Institute was opened in October, 1923, and a large number of illustrations of the building are included in the report. In addition to the usual consulting and waiting rooms, there is an observation ward with accommodation for eight non-thriving babies; a sun-balcony, a toddlers' room where the young children can be left while the mother and baby are awaiting their turn, and a demonstration room for lectures on cooking and sewing. There were 126 cases of pemphigus neonatorum with ten deaths, and Dr. Robertson thinks the importance of this disease as a cause of death has not yet been fully realised. The damage done by ophthalmia neonatorum during 1923 was the worst of any year since this disease came under the purview of the public health committee. There were ten cases of serious damage to eyesight, and six of these will probably be blind children. There was a large outbreak of acute anterior poliomyelitis during the autumn. Of 33 cases notified three died, and 25 of the survivors will be left as more or less complete cripples. There were 29 cases of encephalitis lethargica notified with 12 deaths. Of the 17 survivors only four had made a complete recovery by the end of six months after the attack.

The want of housing accommodation is causing dire distress.

Sheffield.

Dr. Fred. E. Wynne reports that there was an unusual number of cases of enteric fever in Sheffield during the autumn. The cases were distributed throughout the city, and no cause could be assigned for the outbreak. The disease was of a severe type. A table is given in the report showing that of the 17 towns in England and Wales with a population of over 200,000 Sheffield had the lowest death-rate from tuberculosis in spite of the well-known effect of the grinding industry. But the mortality in this industry will not be satisfactory, says Dr. Wynne, until the system of giving out work to the lessees of little, dark, insanitary "wheels" is abandoned in favour of large, economically organised and adequately equipped factories. The large amount of unemployment in the grinding trade has probably been a factor in reducing the incidence of tuberculosis.

The report of Dr. John Rennie, the tuberculosis officer, shows that the dispensary is being well used by the medical profession in Sheffield as a consultation centre. There were no less than 2157 "suspects" examined and the observation beds in the hospitals were largely used. Thirty-eight places are reserved at the two open-air schools for children selected by the tuberculosis medical officer. The fact that 23·7 per cent. of the cases were notified before tubercle bacilli had appeared in the sputum is evidence that pulmonary tuberculosis is being notified at an earlier stage. Infant mortality showed an increase in 1923, the rate being 90 as compared with 82 in the previous year. There were 646 new houses certified in the 12 months ending March 31st, 1924, 278 of which were erected by the corporation. The list of applicants for municipal houses has become hopelessly unwieldy, and many applications of a most pathetic description are received.

The report of Mr. J. S. Lloyd, the veterinary inspector, shows that of 957 samples of mixed milk 7·1 contained tubercle bacilli. The system adopted by the veterinary staff of making immediate microscopical examination of suspected milk has been continued with satisfactory results. By this means cows with tuberculous udders have been eliminated from the milk-supply of the city at an earlier period, and the delay caused by waiting for the result of the "guinea-pig" test has been avoided.

Leeds.

Dr. J. Johnstone Jervis says that more than 60 per cent. of the occupied houses in Leeds are of the back-to-back type. He divides them into three classes—the modern, very good; the old, very bad; and a third class, midway between the other two. It was impossible to analyse the 1923 deaths so as to indicate how many occurred in each of the three classes, but 66·4 per cent. of the total deaths occurred in back-to-back houses, which only slightly exceeds their due proportion. Cremation makes very slow progress in Leeds. During 1920–23 the average annual cremations were about 12, as compared with 11 in 1905–08. Dr. Jervis draws attention to the inadequate number of beds provided at the Leeds General Infirmary. He thinks 1200 beds should be provided instead of 700 as at present. He points out, however, that there is ample accommodation in the Poor-law infirmaries to meet the deficit if it could be brought into use. Perhaps the two most dangerous street nuisances of our time, says Dr. Jervis, are the spitting man and the ill-trained dog. Regulations with regard to underground sleeping rooms made under the Housing, &c., Act of 1909 came into force in September, 1923, and it will now be possible to exercise stricter supervision over owners of flats who allow rooms in basements to be used as sleeping rooms. Progress has been made with regard to the smoke from factory chimneys. One noticeable improvement tending towards smokeless combustion has been effected in the case of a large number of Lancashire boilers by the simple process of shortening the length of the furnace and working on a reduced grate area. The Milk Designations Order has failed to elicit the response anticipated. One licence was issued during the year for certified milk and one for pasteurised milk. In addition the two corporation farms were granted licences by the Ministry of Health for the production of Grade A (tuberculin-tested) milk. The licences were, however, revoked at the end of the year, and these two farms now produce Grade A milk. Only 62 samples of "outside" milk were examined for tubercle bacilli, but five of these, or 8·1 per cent., were found to be infected. Dr. Jervis draws attention to the unsatisfactory state of the law for ensuring the satisfactory disposal of the tuberculous cows found by following up, and would like to see the Tuberculosis Order of 1914 brought into operation. He further states that the cows and cowsheds in the rural districts visited are in a deplorable condition. The accommodation at the Leeds public abattoir is quite insufficient, and its extension and improvement are urgently needed. In last year's report Dr. Jervis expressed his dissatisfaction with the results which were being obtained by the Leeds Antituberculosis Organisation. Towards the end of 1923 he made a special report on the subject which indicated that the tuberculosis mortality-rate had not improved as much in Leeds as in other large towns. In fact, his figures show that the death-rate from pulmonary tuberculosis during 1903–12 was 1·30, as compared with 1·34 for the decennium 1913 to 1922. Dr. Jervis makes several important recommendations, and the reorganisation of the scheme is now in progress.

Bradford.

Dr. John J. Buchan reports that rapid progress is being made with the conversion of privies; 1945 were dealt with in 1923, and there now only remain 5547 to be dealt with. Fish-frying is regulated as an offensive trade. There were 49 applications during the year for permission to establish new fish-frying businesses, all of which were refused. 1046 observations were made of furnace chimneys, and 182 chimneys were found to be either offending or working on the border-line of offence. Proceedings were taken 21 times—namely, against eight owners, six engineers, and seven stokers. The penalties and costs only totalled to £24 18*s*. Dr. Buchan states that many stokers of long experience still retain the practice of covering all the fires at one charge of fuel.

It is estimated that the daily consumption of milk in Bradford is 14,600 gallons, of which 8000 are produced within the city and 6600 outside. There are about 4324 cows stalled inside the city. No mention is made of veterinary inspection, but judging from the experience of Sheffield it ought to be possible to find about 30 tuberculous udders annually among this number of cows. Dr. Buchan says cooling of the milk is not practised to a sufficient extent. Only 105 samples of mixed milk were examined for tubercle bacilli, of which four were found to be infected. The municipal milk depôt obtains its milk from six sources outside the city and about one-eighth of its supply is Grade A (tuberculin tested) milk. Of the 5290 births, midwives attended 3607, only 64 being attended by untrained midwives. Nearly half of the midwives' cases (actually 1531) were attended by the municipal midwives. The supervision of the midwives is undertaken by a woman medical officer, who also does antenatal work and directs the visiting of the expectant mothers done by the municipal midwives. The antenatal visiting of expectant mothers who have engaged non-municipal midwives is undertaken by the health visitors. There is much serious overcrowding. At the end of the year applicants for new houses numbered 5135.

Dr. Buchan's report as school medical officer contains a diagram which indicates the very complete arrangements made by the Bradford Education Authority for dealing with every kind of child. The

X ray treatment of ringworm has been successful. Among the 1792 children treated there has not been a case of recurrent ringworm nor one where there was not full re-growth of hair. In regard to sight deficiency the Bradford authority adopt the practice of supplying the spectacles needed and recovering the cost from the parents. During 1923 1370 pairs of spectacles were supplied and it was only found necessary to remit the cost, owing to the circumstances of the family, in 93 cases. The school dentist, Mr. B. North, reports that 29,197 children were inspected by the four whole-time dentists, 2863 of them being secondary school-children. About 75 per cent. needed treatment. The beautifully situated open-air school at Thackley has accommodation for 190, but this is already found to be insufficient. Some relief will be obtained by the increase of the accommodation at the physically defective school from 190 to 256. The myope school was transferred to a specially constructed and designed open-air school at Daisy Hill, on a site with a southern aspect about 700 feet above sea-level, on July 16th. The benefit to the children has been great.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 22ND, 1924.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 74; scarlet fever, 2099; diphtheria, 1135; enteric fever, 55; pneumonia, 1083; puerperal fever, 40; cerebro-spinal fever, 6; acute poliomyelitis, 19; acute polio-encephalitis, 2; encephalitis lethargica, 43; continued fever, 1; dysentery, 12; ophthalmia neonatorum, 128. There were no cases of cholera, plague, or typhus fever notified during the week. Of the cases of small-pox 15 were notified from Derbyshire (Derby 11, Bolsover 1, Chesterfield R.D. 3), 16 from Lancaster (Ashton-under-Lyne), 4 from Lindsey (Glanford Brigg R.D.), 14 from Yorks, North Riding (Middlesbrough 11, Redcar 1, Scarborough 2).

Deaths.—In the aggregate of great towns, including London, there were 5 deaths from enteric fever, none from small-pox, 13 from scarlet fever, 31 from diphtheria, 50 from measles, 53 from influenza. In London itself the deaths from diphtheria numbered 12 and from infantile diarrhœa 20.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the committee of the Fund 37 cases were considered and £555 voted to 33 applicants. The following is a summary of some of the cases relieved:—

Widow, age 70, of F.R.C.P. Edin. who practised in the Isle of Wight and died last month. Applicant's late husband was in receipt of £2 3*s.* 4*d.* a month from the Fund from June of this year as he had to give up his appointment owing to ill-health. The Royal College of Physicians granted applicant £25 towards funeral expenses and friends gave £10. Applicant is left without means and the Fund voted her a special grant of £10 and £26 in 12 instalments.

Widow, age 58, of M.D. who was a medical officer for 21 years in West Africa and died in April of this year. Applicant has let her flat furnished and is staying with her married daughter whose circumstances do not permit her to help her mother to any great extent. They hope to be able to get a house later so as to take in boarders. The son is at present unable to help his mother. Voted £10.

Widow, age 63, of L.R.C.P. Edin. who practised in Essex and died in 1915. Applicant has been able to help herself up to the present by taking various posts, but had an accident which injured her ankle and she is now lame. Her only income is the eighth share of some property amounting to £40 per annum, but this is not always regularly paid. Her rent is 30*s.* a week. Voted £26 in 12 instalments.

Widow, age 51, of M.D. Durh. who practised in Nottinghamshire and died in 1899. Applicant has paralysis in legs and feet and has tried to help to support herself by teaching music but the average amount received this year was 7*s.* 6*d.* per week. The case was referred to the Fund by the St. Andrew's Society who are allowing her £39 and gave a grant of £5 to help her to canvass for a National Benevolent Institution annuity. The N.B.I. also gave her £12. Voted £18 in 12 instalments.

Widow, age 63, of L.R.C.P. Edin. who practised at Brighton and died in July this year. The long illness of her husband, who was disabled by an accident, resulted in their savings being exhausted. Applicant has managed to let her room for the last three months and received £8 18*s.* 3*d.* The Lodge granted her £10 10*s.* Inclusive rent is £43 per annum. Voted £18 in 12 instalments.

Daughter, age 50, of M.R.C.S. Eng. who practised in Notts and died in 1895. Applicant suffers from tabes dorsalis and finds it hard to support herself. When able she makes sweets and cakes. Her only income apart from this is an annuity of £40 from the Army Officers' Benevolent Fund. Rent amounts to £33 per annum. Voted £18 in 12 instalments.

Subscriptions may be sent to the hon. treasurer, Sir Charters Symonds, at 11, Chandos-st., Cavendish-sq., W. 1.

THE GENERAL MEDICAL COUNCIL.

PENAL CASES.

THE winter session of the General Medical Council opened on Nov. 25th; Sir DONALD MACALISTER presided. His address appeared in THE LANCET of Nov. 29th. Thirteen penal cases came before the Council during the session. The cases were heard in public; the Council deliberated upon them in camera, and the decisions were publicly announced as usual. Two medical cases had been adjourned from previous sessions of the Council. Three names were erased from the Medical Register.

TUESDAY, NOV. 25TH.

The Case of Charles Gilroy King.—The Council proceeded to the consideration of the case of C. G. King, registered as of Pollokshaws-road, Glasgow, L.R.C.S. Edin., M.B., C.M. Glasg., adjourned from Nov. 28th, 1923.

C. G. King was convicted at the sheriff court of Lanarkshire, at Glasgow, on June 21st, 1922, of procuring drugs from a chemist and failing to supply prescriptions and to enter particulars of the said drugs or any portion thereof in a day-book or register kept for the purpose, contrary to the Dangerous Drugs Act, 1920, and regulations made thereunder, and fined £50 or 30 days' imprisonment, and convicted at the same court on June 25th, 1923, on a similar charge, receiving a similar sentence. These prosecutions had been undertaken by the Home Office, whose medical inspector had brought the facts to light. Part of the drugs procured had been dispensed to patients in an ordinary manner, but most of the supply went to Dr. King's wife, who was an addict; it appeared that Dr. King was completely under his wife's influence, and in spite of promises made after the first visit of the Home Office medical inspector, no better care was taken in respect of the registering of drugs. The Home Office authorisation under the Dangerous Drugs Act had been withdrawn from Dr. King, but no question arose as to his having attempted to traffick in these drugs. The Council considered that Dr. King had not fully apprehended his responsibilities under the Dangerous Drugs Act; judgment was postponed for 12 months, with the usual proviso as to unexceptionable behaviour in the interval.

Two favourable reports as to the conduct of Mr. King from medical men practising in his neighbourhood were put in, and a third report from Sir Robert Wilson, of Glasgow. The Council then deliberated on the case in camera and the President announced their decision, that the Council had accepted the evidence in favour of Mr. King and had decided not to direct the Registrar to erase his name from the Medical Register.

The Case of Haydn Brown.—The Council considered the case of Haydn Brown, registered as of Cavendish-square, W., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., who had been summoned to appear before the Council on the following charge:—

> "That, being a registered medical practitioner, you have sought to obtain patients or to promote your own professional advantage by means of an article under your name and professional qualifications, and containing also your portrait, published in *John Bull* of July 19th, 1924, entitled 'Childbirth: Amazing New Discovery!' And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

All the members of the Council were supplied with a copy of the issue of the publication referred to in the charge. Dr. Haydn Brown attended in answer to his notice and explained that he had really no answer to make to the charge, but that he was ready to reply to any questions put to him. In the course of cross-examination he stated that he was rung up on the telephone by *John Bull* as the result of a book which he had published and was asked to write an article on some subject of interest. He accepted the invitation and suggested maternal mortality from child-birth as a suitable subject. He sent typewritten notes of the article to the publication mentioned and shortly afterwards received a typewritten proof which he was asked to approve. He was in a great hurry at the time and read it through quickly and gave his approval. The article as it appeared was somewhat different from the notes which he sent in. In some respects the article, as printed, was, he thought, stronger in its language, and he did not think he had approved the headings. Dr. Brown, however, produced a copy of his original notes and handed them in to the President for comparison with the article as it appeared. The President expressed the opinion that there was not much essential difference between the printed article and the notes, and that in some cases the language used in the notes was stronger than that in the printed article. In further cross-examination Dr. Brown explained his strong belief in his "discovery" and his inability to get the matter taken up in the medical press. He therefore welcomed the opportunity of appealing to the public through the columns of *John Bull* with the idea that the public would then appeal to their doctors to give them the benefit of the new treatment. He himself had given up obstetrical practice 15 years ago, but before doing so had satisfied himself as to the value of "autonomous relaxation." He thought he had tried it in two or three cases. He had used "autonomous relaxation" extensively during the last 15 years, but not in "labour" cases. Dr. Thomson Brown, referred to in the article, had been a pupil of his with regard to "autonomous relaxation." In reply to the President, Dr. Haydn Brown explained that the system was the result of some kind of communication or suggestion from doctor to patient, and that it was a matter of opinion as to whether automatic or autonomous was the better term. When he wrote the article he realised that his appearance before the General Medical Council might be the result. At the same time he realised that such a result would give even greater publicity to the new treatment which he was so anxious to introduce.

The Council then deliberated on the case in camera, after which the President announced its decision as follows:—

"Mr. Brown: I have to inform you that the facts alleged against you in the notice of inquiry having been proved to the satisfaction of the Council, the Council have judged you to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase your name from the Medical Register."

The Case of Jonathan Allan Thornhill.—The Council proceeded to the consideration of the case of J. A. Thornhill, adjourned from the May session.

This practitioner, registered as of Ingleside, Newnham, Glos., L., L.M. R.C.P. Irel., L., L.M. R.C.S. Irel., had been summoned to appear before the Council on the following charge: "That being a registered medical practitioner: (1) On April 15th and 18th, 1923, while attending a Mr. J. P., who was seriously ill from influenza, you were so far under the influence of drink that your power of judgment and sense of responsibility were affected to a degree rendering you unfit to be in charge of a serious case of illness. (2) On April 23rd, 1923, you gave to the said J. P. a National Health Insurance certificate stating that you had examined him on that date and that he was incapable of work by reason of broncho-pneumonia, whereas you had not seen or examined the said J. P. on that date or since April 18th, 1923; which certificate was untrue, misleading, or improper; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect." The Council found that the first part of the charge had not been proved to their satisfaction, and as regards the second part they suspended judgment till November of this year.

Two testimonials as to Dr. Thornhill's satisfactory conduct during the period of probation from brother practitioners, and one from a minister of religion were submitted. In reply to the President, Dr. Thornhill gave his assurance that he would in future exercise due care in the issue of certificates. The Council deliberated in camera and the President announced its decision that the Council did not see fit to direct the Registrar to erase the name of Jonathan Allan Thornhill from the Medical Register.

The Case of Kul Want.—The Council proceeded to the consideration of the case of Kul Want, of Rock House, Retford, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., who had been summoned to appear before the Council on the following charge:—

> "That being a registered medical practitioner, you on June 30th, 1924, signed and issued the following certificate, viz.:—
>
> 30.6.1924.
>
> I Hereby Certify that *F. B.*
> residing at *14 George Street*
> is suffering from *Bronchitis*
> and is unable to follow his employment *school for 14 days.*
> *K. WANT,*
> Surgeon.
>
> —whereas you had not seen or examined the said F. B., who was, in fact, quite able to attend school, which certificate was untrue, misleading, or improper. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The Council's solicitor put in the statutory declaration of Mr. Hill, schools attendance officer of Retford, and called Mr. Hill as a witness to prove the facts stated in the charge. Mr. Want went into the witness-box and explained that he had a long attack of bronchial asthma during the summer of 1924 and was confined to bed for a considerable period. On June 30th he was ill in bed and came down feeling very bad to see some patients, having at the time no locum tenens. Among those waiting was Mrs. B., who said her son F. had a similar attack of bronchitis to that for which Mr. Want had previously attended him. She asked to be supplied with the same medicine as the boy had had before. She then asked for a certificate that he was unfit to attend school. Mr. Want was expecting a new locum tenens on this day and gave the certificate, thinking that the new locum tenens would be able to visit the Broughtons when he arrived. As it turned out the new locum tenens did not arrive until July 2nd. Mr. Want further stated that the giving of a certificate under these circumstances was an isolated occurrence, and he gave an assurance that he would exercise greater care with respect to the signing of certificates in future. Mr. le Brasseur submitted testimonials as to the esteem in which Mr. Want was held in Retford and as to his good public work.

The Council deliberated on the case in camera, and the President announced its decision that the Council found the facts in the charge proved and that Mr. Want's explanation was no excuse for the laxity shown in the issue of the certificate. The Council were, however, prepared to accept Mr. Want's statement that this was an isolated occurrence and his assurance that he would exercise great care in the issue of certificates in the future.

Wednesday, Nov. 26th.

The Case of John Evans.—The Council then proceeded to the consideration of the case of John Evans, of High-street, Yiewsley, Middlesex, M.R.C.S. Eng., L.R.C.P. Lond., who had been summoned to appear before the Council on the following charge:—

> "That, being a registered medical practitioner, you issued seventy-nine medical certificates required for National Health Insurance purposes (Form Med. 40 Revised) to an insured person—namely, one George Stevens—in respect of the period from Sept. 5th, 1923, to March 11th, 1924, including the final certificate dated March 11th, 1924, without seeing the said George Stevens on or between these dates and without any medical examination of the said George Stevens, such certificates being untrue, misleading, or improper. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The Council's solicitor showed that the offence mentioned in the charge had been the subject of an inquiry by the Insurance Committee, and that Mr. Evans had been fined £30 by the Minister as a result of the findings of the Insurance Committee and that the documents with regard to the inquiry had been forwarded to the General Medical Council. Mr. Williams, solicitor, appeared for Mr. Evans and subnitted declarations from Mr. Evans, from the dispenser of Mr. Evans, and from the patient, George Stevens, all three of whom were called as witnesses. Mr. Evans stated that Stevens suffered from obscure abdominal symptoms and that, not being satisfied with his progress, he recommended him to attend St. Mary's Hospital, but continued to issue weekly certificates stating that Stevens was unable to work during the period mentioned in the charge because he thought Stevens was still attending the hospital. He thought it was his duty to issue these certificates as panel doctor because Stevens would be unable to obtain his money without the certificates. The dispenser gave evidence that the weekly certificates were usually called for by Stevens's daughter, aged about 14, or Stevens's son, aged about 10, and that she frequently asked the children if their ather was still attending the hospital. The patient, George Stevens, stated that he was asked to visit the regional officer on March 11th, 1924, and that he was informed that he was fit for light work. He then visited Mr. Evans and received the final certificate. Mr. Evans admitted that he had seldom seen Stevens during the whole period of the issue of the weekly ertificates, although each certificate certified that he, Mr. Evans, had seen Stevens on the date of issue of each certificate.

The Council deliberated on the case in camera. The President announced its decision. The Council ound that the charge was not proved with regard o the final certificate, but that it was proved with egard to the bulk of the certificates. The Council onsidered there had been very great laxity in the ssue of these certificates deserving of severe censure. They took a serious view of the case and judgment would be postponed until the session of the Council n November, 1925, when Mr. Evans would be required o submit testimonials as to his conduct from professional brethren or other persons of repute.

The Case of William Lovell.—The Council proceeded o the consideration of the case of William Lovell, egistered as of Westbere-road, West Hampstead, N.W., L.S.A. Lond., M.R.C.S. Eng., L.R.C.P. Lond., who had been summoned to appear before the Council n the following charges :—

(*a*) "That you have been convicted of the following isdemeanours, viz.: (1) On Sept. 15th, 1905, at the West London Police-court, of being drunk and disorderly, or which you were fined 7*s.* 6*d.*; (2) on Sept. 19th, 1913, t the Marylebone Police-court (under the name and escription of Harry Johnson, clerk), of being drunk, for which you were fined 5*s.* and 18*s.* costs ; and (3) on April 4th, 917, at the Marylebone Police-court, of being drunk, for which you were fined 10*s.* ; and

(*b*) "That, being a registered medical practitioner, and a Lieutenant in the Royal Army Medical Corps, you were on April 5th, 1918, tried by a general court-martial in East Africa on a charge of drunkenness whilst on active service, f which charge you were found guilty and sentenced to be ismissed from His Majesty's Service, the finding and entence being duly confirmed.

"And that in relation to the facts so alleged you have been uilty of infamous conduct in a professional respect."

The Council's solicitor showed that various letters f apology had been received from Mr. Lovell with egard to the charges, and that in 1918 Mr. Lovell's ame had been erased from the Register owing to umour that he was dead. Two letters were put in from Mr. Lovell and his wife, but Mr. Lovell did not attend.

The Council deliberated on the case in camera, nd the President announced its decision that the harges were found to be proved and that the egistrar had been directed to erase the name of William Lovell from the Medical Register.

The Case of Charles Adolphus Sampson.—The ouncil proceeded to the consideration of the case of harles Adolphus Sampson, registered as of Harley-reet, London, W., L.S.A., L.M.S.S.A. Lond., who ad been summoned to appear before the Council n the following charge :—

"That, being a registered medical practitioner, you have ught to obtain patients or to promote your own professonal advantage by means of an article contributed by you to the *Daily Express* of Sept. 4th, 1924, entitled 'Psycho-Analysis is Dead, by Dr. Charles Sampson (Director of the London Clinic of Applied Psychology and Psycho-therapy).' And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

Mr. Oswald Hempson, solicitor of the Medical Defence Union, appeared for Mr. Sampson. The Council's solicitor read extracts from the article in the *Daily Express*. Mr. Sampson gave evidence in his own behalf. He said his was a consulting and treatment practice and that he only saw cases sent to him by other doctors. He explained the genesis of his article. An article by Dr. Herbert Bousfield appeared in the *Sunday Express* boosting "Psycho-analysis." In consequence he had requests from patients and also verbal requests from medical colleagues to answer the article. He rang up the *Sunday Express* and asked if they would be willing to insert an article by him as a rejoinder to Dr. Bousfield's article. They agreed to do so and he prepared his article and sent it in. He heard nothing more until on returning from abroad he was informed that the article had appeared in the *Daily Express*, and was congratulated by the editor of a medical paper on his article. He rang up the *Sunday Express* but was unable to find out how his article had got into the *Daily Express*. The change of paper did not fulfil his purpose as the article no longer appeared as a rejoinder to the article of Dr. Bousfield. The sub-headings in the article were not his and no proof was submitted to him for correction. He was surprised to receive a cheque for £3 3*s.* for the article, as he had expected no payment. In answer to the President, he said the article was not intended to be self-laudatory or egotistical, but his desire was to show forcibly the harm done by psycho-analysis. He had no influx of patients since the writing of the article and still only saw cases sent him by other doctors. The clinic referred to in the article was carried on at his own house for the benefit of patients sent to him by other doctors as unable to pay fees. The clinic was conducted on the same lines as the mother-clinic in Paris, on the staff of which were many well-known French doctors. He knew several doctors in this country who were using successfully the same treatment as that adopted at the London and the Paris clinic. The London clinic was established in 1908. Sir Herbert Waterhouse testified in favour of Mr. Sampson, whom he had known for 23 years. He knew that Mr. Sampson had treated many soldiers suffering from shell-shock and many hysterical women at his clinic and had taken an infinity of trouble without getting a penny for it. Dr. Hubert Roberts (senior surgeon, Queen Charlotte's Hospital) also expressed his high opinion of Mr. Sampson and his work. He had known Mr. Sampson for five years and had seen a good deal of him as Mr. Sampson was actually his tenant. Mr. Sampson was a most unlikely man to advertise himself for possible material benefit. Dr. Roberts's complaint against him was, on the contrary, that he made appointments with paying patients and failed to keep them.

The Council deliberated on the case in camera. The President announced its decision. The Council found the charge with regard to the writing of the article to be proved and thought it was a most improper article to communicate to the lay press. The Council, however, did not think that Mr. Sampson had written the article for the purpose of obtaining patients or self-advertisement, and accepted his assurance that he would be more careful in future, and the testimony in his favour given by his medical colleagues. There would be no judgment.

THURSDAY, NOV. 27TH.

The Case of Patrick Joseph Corcoran.—The Council then proceeded to the consideration of the case of Patrick Joseph Corcoran, registered as of Ballycastle, Co. Mayo, M.B., B.Ch., N.U. Irel., who had been summoned to appear before the Council on the following charge :—

(*a*) "That, being a registered medical practitioner, and a Lieutenant in the Royal Army Medical Corps, you were on

March 15th, 1915, tried by a general court-martial on a charge of having been drunk at Bethune, of which charge you were found guilty and sentenced to be dismissed from His Majesty's Service. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

(*b*) "And that you have been convicted of the following misdemeanours, viz.: On July 23rd, 1924, at the Clerkenwell Police-court, of being drunk whilst in charge of a motor-car, for which you were fined 40*s*. and £10 10*s*. costs, and your licence was suspended for three months and endorsed; and on August 14th, 1924, at the South-Western Police-court, of driving a motor-car negligently, for which you were fined £5 and £5 5*s*. costs."

Mr. Hempson, of the Medical Defence Union, appeared for Dr. Corcoran. The facts of the court-martial were reported to the Council by the Judge Advocate-General, who also reported that Dr. Corcoran had been reappointed to a commission on Nov. 9th, 1918. Dr. Corcoran gave evidence in his own behalf and stated that he was ordered to France in October, 1914. He was first sent to a base hospital and volunteered for the front. When on a day's leave at Bethune he dined with friends. At this time recruiting in Ireland was bad and he lost his temper owing to some insulting remarks made about his country. He was court-martialled and did not attempt to defend himself. He was reinstated in the army in 1918 and gazetted out as captain in 1920. He had contracted malaria during service. He was in practice at Battersea, in partnership with Dr. M. J. Macaulay. The two police-court prosecutions had reference to what occurred on July 11th, 1924. July 11th was the first day of his holidays. He was feeling the effects of the malaria and had no breakfast, but a whisky and soda instead. He had arranged to meet his people at Euston and motored in. Still feeling bad he had another whisky and soda and became unfit to drive the car. He was taken to the police-station and detained for three hours. After which he drove to Euston and conveyed his people to their rooms in Guilford-street. In the evening he drove home, and about midnight he started out to visit his partner to explain the occurrence at the police-court. He came into collision when quite sober and this constituted the second police-court charge. A letter was put in from Dr. Corcoran's partner stating that Dr. Corcoran had given complete satisfaction in the practice, and that apart from this single occurrence there was absolutely nothing against him.

The Council deliberated on the case in camera, and the President announced its decision that the Council trusted Dr. Corcoran's assurance that he would be an abstainer for the rest of his life and had not seen fit to instruct the Registrar to erase his name from the Medical Register.

The Case of Alexander Dawson Reid.—The Council then proceeded to the consideration of the case of Alexander Dawson Reid, registered as of High-street South, East Ham, E., M.B., Ch.B. Aberd., who had been summoned to appear before the Council on the following charge:—

(*a*) "That, being a registered medical practitioner, and a Lieutenant in the Royal Army Medical Corps, you were on August 16th–17th, 1917, tried by a field general court-martial on a charge of being drunk in the field, of which charge you were found guilty and sentenced to be dismissed from His Majesty's Service. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

(*b*) "And that you have been convicted of the following misdemeanours, viz.: On December 1st, 1919, at the East Ham Police-court, of being drunk whilst in charge of a motor-car, for which you were fined 40*s*. and 7*s*. 6*d*. doctor's fee, or 31 days' imprisonment; on Feb. 9th, 1923, at the Stratford Police-court, of being found drunk, for which you were fined 10*s*. and £2 2*s*. costs, or fourteen days' imprisonment; and on Sept. 16th, 1924, at the West Ham Police-court, of driving a motor-car in a dangerous manner, for which you were fined £15, or two months' imprisonment."

Mr. Hempson, of the Medical Defence Union, appeared for Dr. Reid. Mr. Harper, the Council's solicitor, wished to amend the charge on the information received from the Judge Advocate-General that there had been two court-martials in the case of Dr. Reid. The first court-martial was on May 9th, 1917, and resulted in forfeiture of seniority of rank. The second court-martial was in Palestine. In both cases the charge was of being drunk. Dr. Reid gave evidence in his own behalf and explained that as the result of an attack of blood poisoning he had become subject to giddiness. At the time of the first court-martial he was just recovering from enteric fever and had heard of the death of his brother in France. He had had some whisky, came out of the club, and was getting into a trap when the pony started. He fell into the trap and a senior officer who saw the occurrence assumed that he was drunk. Dr. Reid also denied that he was drunk on the occasion charged at the second court-martial. He was surprised at receiving the notice of the second court-martial and resigned his commission. The court-martial was held, nevertheless, and he pleaded "Not guilty." He attributed the results to the fact that his physical disabilities were not understood. After leaving the Service he took a practice at East Ham which he had had for seven years, and worked up from £500 to £1400 in value. He denied that he had been drunk on any of the occasions included in the police-court charges. On the third occasion he was charged with being drunk, but this charge was quashed on appeal, and Sir J. Purves Stewart gave evidence as to his liability to attacks of giddiness. Evidence was given in support of Dr. Reid by a medical friend, who had known him as a student and was able to speak as to the great change in him as the result of the attack of blood poisoning. Mr. Robert Crosby, manager of Barclay's Bank at East Ham, who had known Dr. Reid intimately for seven years, and a veterinary surgeon in East Ham, who had known him intimately for two years, gave evidence as to Dr. Reid's habitual abstemiousness. Mr. Hempson pointed out that the only occasion on which Dr. Reid had made an appeal against the conviction for drunkenness had been successful. It was admitted that he had had some drink on each of the occasions referred to, but if a man with his physical disabilities smelt of drink it was quite sufficient for a stranger to assume that he was drunk.

The Council deliberated on the case in camera, and the President announced its decision that the Council found the charges proved, but under the circumstances had decided to postpone judgment for 12 months, at the end of which time Dr. Reid would be required to produce the evidence of persons of repute in his neighbourhood as to his conduct. Dr. Reid gave an assurance to the Council that he would abstain altogether from alcohol in the future.

The Case of David Williamson Anderson.—The Council then proceeded to the consideration of the case of David Williamson Anderson, registered as of Princess-road, Seaham Harbour, Co. Durham, L.R.C.P., L.R.C.S. Edin. L.F.P.S. Glasg., who had been summoned to appear before the Council on the following charge:—

"That you have been convicted of the following misdemeanours, viz.:—

"(*a*) On April 10th, 1923, at the Newcastle-upon-Tyne Police-court, of being drunk, for which you were fined 10*s*.

"(*b*) On May 8th, 1924, at the South Shields Police-court, of being drunk whilst in charge of a motor-car, for which you were fined 10*s*., and ordered to pay for use of ambulance; and

"(*c*) On July 10th, 1924, at the Gateshead Police-court: (1) Of being drunk in charge of a motor-car, for which you were fined 40*s*., or fourteen days' imprisonment; (2) of driving to the danger of the public, in contravention of the Motor Car Act, 1903, for which you were fined £20 and ordered to pay the solicitor's fee of £2 2*s*. and witnesses' fees of £1 16*s*., or fourteen days' imprisonment; and (3) of failing to give audible warning, in contravention of the Motor Cars (Use and Construction) Order, 1904, for which you were fined 20*s*., or 14 days' imprisonment."

Mr. Harper, the Council's solicitor, stated that no defence or answer had been sent in by Mr. Anderson, who was not present. Mr. Anderson had, however been in attendance during the previous day.

The Council deliberated on the case in camera, nd the President announced its decision to adjourn e case until the following day in order to give r. Anderson another chance of being present.

The Cases of John Joseph Brennan, Francis Pulteney lood, and Vivian Thomas Pearce Webster.—The ouncil then proceeded to the consideration of the llowing three cases, taken together. (1) John oseph Brennan, of Maeryrhaf, Merthyr Tydfil, .R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., who had een summoned to appear before the Council on the llowing charge :—

"That, being a registered medical practitioner, you signed nd issued a certificate dated March 26th, 1924, that one illiam Jones was suffering from weakness after abscess of kle and required temporary relief, whereas you had not en or examined the said William Jones, which certificate as untrue, misleading, or improper. And that in relation the facts so alleged you have been guilty of infamous nduct in a professional respect."

(2) Francis Pulteney Flood, of Frondeg, Merthyr ydfil, M.R.C.S. Eng., L.R.C.P. Edin., L.S.A. Lond., ho had been summoned to appear before the Council n the following charge :—

"That, being a registered medical practitioner, you signed nd issued a certificate or statement dated May 14th, 1924, ating that one William Jones was unable to work, whereas u had not seen or examined the said William Jones, which rtificate was untrue, misleading, or improper. And that relation to the facts so alleged you have been guilty of famous conduct in a professional respect."

(3) Vivian Thomas Pearce Webster, of Tygwyn, erthyr Tydfil, M.R.C.S. Eng., L.R.C.P. Lond., who ad been summoned to appear before the Council on he following charge :—

"That, being a registered medical practitioner, you gned and issued five certificates or statements dated pril 9th and 12th, May 21st and 27th, and June 11th, 24, stating, as regards the first three, that one William ones had been idle for three weeks and, as regards the st two, that he was suffering from a chronic ulcer of the g and was unable to work regularly, whereas you had not en or examined the said William Jones except, possibly, one occasion, which certificates or statements were untrue, isleading, or improper. And that in relation to the facts alleged you have been guilty of infamous conduct in a rofessional respect."

Mr. Le Brasseur appeared for Mr. Brennan privately, nd for Mr. Flood and Mr. Webster, acting on behalf f the London and Counties Medical Protection ocieties, and raised the point that there was no vidence against Mr. Flood. The President agreed nd Mr. Flood was discharged from the case. Mr. arper, the Council's solicitor, explained that the two harges arose out of the prosecution of a Mrs. Jones, f Merthyr Tydfil, for obtaining about £20 in poor lief on the grounds that her husband was ill and nable to work, whereas during most of the period e was earning £2 a week or more. Mr. Harper ead a newspaper account of the proceedings before he stipendiary magistrate, from which it appeared hat Mrs. Jones had been enabled to get her poor lief through the certificates forming the subjects of he charge. The magistrate severely criticised the xity shown by the doctors in granting these certicates and suggested that they ought to repay the 20 to the guardians. He, the magistrate, was in difficult position, because he could not fine Mrs. ones or send her to prison, her husband's earnings ere not sufficient to keep her and her eight children, nd fine or imprisonment would make the position f the children worse. Mr. Webster stated that he ttended the Jones family gratuitously. He was ot the Poor-law doctor and Jones was not on his anel. Mrs. Jones called him in when he was visiting ear her house to look at her husband's ankle, hich was ulcerated. He considered that Jones was nfit to work and he gave the certificates out of indness to help Mrs. Jones to get the relief to which he appeared to be entitled. He had no idea that ones was going to work during the period covered y the certificates and realised now that what he had ertified was untrue. Mr. Brennan stated that he was the Poor-law officer for the district. When Mrs. Jones called to see him with a note from the relieving officer and Mr. Webster's certificate he was very busy and could not have visited Jones that day. He therefore gave a certificate without seeing Jones, relying on the certificate of Mr. Webster in order to enable Mrs. Jones to get her relief promptly. The Jones family lived about three miles from his house and he had seen Jones about 18 months before when vaccinating the baby. He had been asked to look at the ankle.

The Council deliberated on the case in camera. The President announced its decison. The Council found the facts proved against Mr. Brennan and that he had been guilty of great laxity deserving of severe censure. The Council hoped that these proceedings would act as a warning and had decided to postpone judgment for six months, at the end of which time the usual testimony as to conduct, especially as to the granting of certificates, would have to be produced. The Council also found the facts proved against Mr. Webster and that he, too, had acted laxly. In his case, too, judgment would be postponed for six months, at the end of which time testimonials would have to be produced as to conduct.

Friday, Nov. 28th.

Erasures from the Dental Register.

There were four erasures from the Dental Register for various offences and in none was any appearance put in by the incriminated person.

The Case of David Williamson Anderson.

The President announced that this name had been removed from the Register.

Reports Submitted.

Reports from the following Committees were received : Public Health Committee, Pharmacopœia Committee, Education Committee, Examination Committee, and Dental Examination and Education Committee, as well as one from the Finance Committee.

Broadcasting.

The Council considered in camera the position of registered medical practitioners delivering public addresses for purposes of broadcasting. The matter was brought before them at the previous session, but no public announcement was made.

The Council rose on Friday afternoon.

The Direct Representatives to the Council.

At the meeting of the Branch Council for England, held on Nov. 25th, Sir Donald MacAlister, the Chairman, announced that the following was the result of the voting at the election of Direct Representatives for England to be members of the General Medical Council :—

HENRY BRITTEN BRACKENBURY, M.R.C.S.	11,486
ROBERT ALFRED BOLAM, O.B.E., M.D.	10,087
Sir THOMAS JENNER VERRALL, M.R.C.S.	9620
JAMES ALEXANDER MACDONALD, M.D.	9143
Frederic Hibbert Westmacott, C.B.E., F.R.C.S.	3310
Henry Jasper Cardale, M.B.	2953
Robert Fielding-Ould, M.D.	2833
Gordon Reginald Ward, M.R.C.S.	2685
Harry François Devis, M.R.C.S.	2580
Edward Andrew Gregg, L.R.C.P. & S.	2125
John Brown, M.D.	1089

The first four will consequently be Direct Representatives for five years from Jan. 1st, 1925.

Sir Malcolm Morris Memorial Fund. — The hon. secretary of the committee announces that Sir John Broadbent and Dr. Ronald C. Macfie have sent donations to this Fund. The total subscribed to date is £479 6*s.* 2*d.*, and the committee earnestly hope that this sum will be made up to £500 at an early date as it has been decided to close the appeal at the end of December. Further subscriptions to that end will be very gratefully acknowledged if forwarded to the hon. treasurers, "Sir Malcolm Morris Memorial Fund," at 12, Stratford-place, London, W. 1.

Correspondence.

"Audi alteram partem."

GENERAL MEDICAL COUNCIL ELECTION.

To the Editor of The Lancet.

Sir,—Will you allow us to express our united thanks to the registered medical practitioners—electors in England and Wales—who have given us so marked a proof of their confidence in the election just concluded? We offer our assurance of continued endeavour as their Direct Representatives on the General Council to look after their interests during the period of office which begins next year.

We are, Sir, yours faithfully,
R. A. Bolam.
H. B. Brackenbury.
J. A. Macdonald.
T. Jenner Verrall.

Dec. 1st, 1924.

THE INFLUENCE OF THE VAGUS CENTRE IN CHLOROFORM NARCOSIS.

To the Editor of The Lancet.

Sir,—The action of chloroform on the vagus centre and on the heart has been studied by many observers, but the interpretation of its effect is in some respects still doubtful. In the course of experiments on some 150 dogs in recent years, I have remarked certain symptoms which are not satisfactorily explained by the present views on the subject. In some animals (used for bleeding purposes only) chloroform constituted the sole anæsthetic given, and those referred to in this note belong exclusively to that category. The process of bleeding the first dog for heart-lung work is usually a hurried one, owing to the exigencies of the main operation. The chloroform at first causes inhibition of respiration, and this is followed by deep inspirations with which it is all too easy to give an overdose. In such a case, when the respiration and heart beats stop, the usual procedure is to make an opening in the abdominal wall, insert the finger, and massage the ventricle through the intact diaphragm, using the other hand as a *point d'appui*, and at the same time making the hand serve to effect artificial respiration, with the tongue pulled out, &c. Sometimes it is necessary to attach the respiratory pump to the trachea. Occasionally the respiration returns without restoration of the heart beat, but, this again failing, the animal may die. Respirations of this sort are evoked reflexly by the somatic and vagus nerves, the lung being pressed as well as the thoracic walls and the centre recovering some of its reflex excitability.

I have elsewhere[1] drawn attention to the necessity of distinguishing between reflex excitability and tone when testing the effects of hæmorrhage on bulbar centres, McWilliam having made a similar distinction when testing the effects of chloroform.[2] There are differences in the resistance and recuperative power of the bulbar centres, as has been shown by the writer,[1] by Bayliss,[3] and others, and the respiratory centre shows variations like the vaso-motor and the cardio-inhibitor. The breathing referred to above as occurring during massage is rhythmical, not of the gasping type seen as the centre is failing with anæmia or asphyxia. The stoppage of the heart occurs early in the administration, and is not due to toxic effect on the muscle of the walls. Its causation will be discussed in a moment. McWilliam, working on cats, found that stimulation of afferent nerves may cause temporary standstill of the heart under chloroform, but it is a reflex which he found very difficult to elicit. He also attributes stoppage to the effect of asphyxial blood, but beyond these two aspects of arrested beat he deals simply with variations of rate short of cessation. He goes so far as to say that the vagus centre is not necessarily paralysed in deep chloroform narcosis, in which its tone may be active. Dogiel[4] says chloroform first stimulates the vagus and then paralyses it. Kappeler[4] noted that the heart beat faster on cutting the vagi in fairly deep narcosis. Pharmacologists generally admit a transitory excitation of the vagus by the drug, and this is interpreted in a recent work on the subject[5] as due to a hyperexcitable state of the medulla "when freed from the restraining influence of the higher centres." The greatly increased excitability in response to extraneous stimuli is here looked upon as the cause of slowing of the heart. There is no suggestion of a direct stimulation of the cardio-inhibitor centre by which its tone is increased, but such direct action, it seems to me, will best explain the facts.

In some four or five animals the conditions, accidentally occurring or purposely produced, were as follows: The heart in complete standstill was massaged without effect for periods of half to one minute when an assistant was directed to cut the vagi, previously exposed or after a short delay for dissection. Section of one nerve caused either the occurrence of a few spontaneous beats or beats in response to pressure, but the section of the second trunk instantly set up a rapid and forcible rhythm. In other instances where the drug was pushed to produce like effects, cutting of the nerves was followed either by a few beats or by no change, and it was only after the use of the respiratory pump and squeezing the heart through an opening in the diaphragm that rhythmic beats were restored, very slowly and irregularly. In such cases as these the musculature was obviously affected by the drug, and even then some vagus tone was evident. This excessive tone of the centre not only holds up rhythmic activity, but prevents response to mechanical stimulation. It is remarkable that the condition may last long enough to cause ultimate failure of the heart at a time when the respiratory centre seems capable of responding to a due supply of blood and to reflex stimulation.

The chief indication for treatment is to cut off the tonic impulses from the centre. Injection of atropine with an arrested circulation must be useless. In the work already referred to[1] it has been shown how to block conduction in the exposed vagus nerve without injury to its functions—namely, by the passage of a constant current through it of E.M.F. about one volt. Function is quickly and fully restored on breaking the circuit, whereas the method of freezing the nerve for this purpose leaves conductivity depressed for a long time afterwards or even abolished in some cases. I have not been able to test the possibilities of this method by application through the unbroken skin.

I am, Sir, yours faithfully,
D. T. Barry, M.D., D.Sc., F.R.C.S.

Cork, Nov. 29th, 1924.

LABORATORY CHANGES AT A HOSPITAL.

To the Editor of The Lancet.

Sir,—The attention of the Medical Committee a the Hospital for Epilepsy and Paralysis has bee drawn to the letter in your issue of Nov. 22nd signe by Drs. J. G. Greenfield, D. Nabarro, and A. Piney They do not consider it necessary to defend th principle of a hospital laboratory undertaking clinico pathological work for "*medical practitioners for th benefit of their patients who are not in a position t pay the usual charges*," which the circular complained of states. With regard to the staff of th laboratory, in the same issue of The Lancet, p. 1102 will be found a paragraph explaining shortly th scheme and personnel of the laboratory which has recently been opened.

We are at present fortunate in the fact that ou honorary pathologist is able to spend most of ever day at the hospital. His chief assistant is an M.Sc. Lond., an honours graduate, who for 15 months studied at the Central Pathological Laboratory of the London County Council under Sir Frederick Mott, and later under Dr. Golla, and is undoubtedly a highly qualified biochemist, with special bacteriological training in this laboratory, which draws its material from about 25,000 beds.

---

[1] Barry: Brit. Jour. Exp. Path., 1923, iv., 92.
[2] McWilliam: Jour. Physiol., 1900, xxv., 233.
[3] Bayliss: Intravenous Injection in Wound Shock. London: Longmans. 1918.
[4] Dogiel: Quoted by McWilliam, loc. cit.
[5] Cow: Pharmacology, p. 51. London: Churchill. 1920.

The Medical Committee are highly satisfied with the way in which the laboratory is working, both for the hospital and for those private practitioners who have already made use of its facilities.

I am, Sir, yours faithfully,
H. W. BURLEIGH,
Secretary and General Superintendent, Hospital for Epilepsy and Paralysis, Maida Vale, W.
Nov. 26th, 1924.

PS.—Since the Medical Committee drafted the above letter, which was too late for insertion in your issue of last week, another letter signed by Dr. J. A. Murray has appeared on the same subject. This adds nothing to what was said before, as Dr. Murray also has not ascertained the facts from the hospital.

Nov. 29th, 1924. H. W. B.

THE EFFECT OF SPLENECTOMY ON THE PRODUCTION OF EXPERIMENTAL PURPURA.

To the Editor of THE LANCET.

SIR,—The authority with which Dr. S. P. Bedson writes on the subject of blood platelets is fully recognised, and his article on the above subject in THE LANCET (Nov. 29th, p. 1117) is an interesting and valuable addition to the reports of his experimental work. When, however, he extends his conclusions to the clinical field and writes that "(5) splenectomy cannot be relied on to give any but temporary relief in the treatment of purpura hæmorrhagica," he goes too far.

In the first place, experiments dealing with the artificial production of purpura in animals cannot be accepted as settling the question of the treatment of acquired purpura hæmorrhagica in human beings. Secondly, splenectomy has afforded far more than temporary relief as a treatment for purpura hæmorrhagica. Kaznelson's patient, the first case operated on, had had no recurrence of the disease five years later. Other cases, recorded in America, have remained free from any symptoms of the disease (purpura hæmorrhagica) up to the date of publication—namely, from 6 to 12 months after the operation. American writers hold strongly that splenectomy is a really curative treatment in the thrombocytopenic type of purpura hæmorrhagica.

I am, Sir, yours faithfully,
London, Dec. 1st, 1924. G. A. SUTHERLAND.

THE ALLEGED STERILITY OF PRESENT-DAY BACTERIOLOGY.

To the Editor of THE LANCET.

SIR,—It cannot be a surprise to many to find that the time has arrived when orthodoxy in bacteriology must perforce defend itself against the charge of stagnation. Dr. Ledingham's letter in your issue of Nov. 22nd (p. 1095) is probably the first of many such apologias. His easy-going disposal of the great heterodoxy of "bacterial cycles" as the offspring of an exuberant imagination and faulty technique is characteristic of the exponents of what many believe to be a dying era. Many instances could be cited of the reluctance of the community of monomorphic bacteriology to grapple with realities. Take, for example, influenza. Pfeiffer described a bacillus. Donaldson, from every case examined, obtained an extremely pleomorphic organism; it grew as bacilli and as cocci, and Donaldson suggested there might be a filtrable phase. Later Fry described yeast-like bodies which were capable of giving rise to bacilli. Wade and Manalang then discovered that under certain conditions Pfeiffer's bacillus could grow into large fungal forms, and declared the bacillus to be merely "a simple form of an organism capable of complex development." Reed and Orr confirmed these findings and showed that a simple alteration in the H-ion concentration of the medium was sufficient in all cases to induce the minute bacillus to grow into large hyphal and yeast-like forms. Olitsky and Gates added to the confusion by describing a filtrable form, but on occasions this grew as a comparatively large body. Finally Beaumont obtained a hyphomycete which grew in the following alternative phases: large spores, hyphæ, cocci, and bacilli, and suggested that influenza is really a mycosis, and that the many alternative phases in which the causal fungus could exist might "afford a means of unifying the seemingly discordant results that have been obtained by other workers." In view of all the facts is this unlikely? Monomorphic bacteriology vetoes it because bacteria are monomorphic! Henri obtained yeast, coccal and branching forms from *B. anthracis.* Monomorphic bacteriology says these are merely contaminations! Klebs and Malassez and Vignal many years ago described an amorphous and granular phase of the tubercle bacillus. During 40 years these observations were out of keeping with the dictates of monomorphism and they were submerged. Recently Valtis, Vanucci, and others have described a filtrable phase of the tubercle bacillus. Nothing but faulty technique! Löhnis, in a massive piece of work, has shown that many bacteria can grow alternatively as bacilli, cocci, yeasts, &c., and he has claimed that the secret of bacterial morphology is the bacterial plasm, from which, just as from the germ-plasm of higher organisms, a variety of differentiated elements, each capable of true-to-type propagation, can be obtained. They can grow as separate and distinct entities in separate test-tubes just as, from the same animal, the epithelial cells of the kidney can grow in one tube and the connective-tissue cells in another.

Is all this, and a hundred and one similar observations by other careful workers, merely a tissue of self-deceptions originating in an exuberant imagination and a faulty technique? Is it not rather one of those great facts that usher in a new era?

I am, Sir, yours faithfully,
Edinburgh, Nov. 27th, 1924. JAMES YOUNG.

THE CLINICAL SIGNIFICANCE OF CONSTIPATION.

To the Editor of THE LANCET.

SIR,—When we treat a patient for constipation, our aim in doing so is to save him from absorbing intestinal toxins, the condition being one that may be dependent upon a person's habits of life or upon individual idiosyncrasy. Many people take only two meals a day, and will defæcate less often than those whose meals number three or four. Dr. A. Hurst, in Constipation and its Allied Disorders, gives 40 hours as the limit, and calls a condition in which the action of the bowels is deferred beyond this period constipation.

It is important to note that, if the evils of constipation are admitted, it by no means follows conversely that easy and free habits in this respect necessarily denote health. The most remarkable case of cancer of the colon that I ever remember occurred in a man who had never in his life suffered from constipation; his usual habit being two easy actions daily. Whilst apparently in perfect health he was suddenly seized with complete obstruction, a laparotomy revealing a growth at the sigmoid flexure of the colon. The vast majority of those who suffer from intestinal putrefaction and its consequences, so far from being constipated, are accustomed to two or three soft, badly coloured, slightly offensive motions daily; and in dealing with the functions of the lower bowel, the only safe method to employ is to subject the fæces to chemical and bacteriological examination. A very frequent type of stool is alkaline in reaction, and contains Gram-positive organisms far in excess of the normal. This is, I think, invariably an indication for the use in treatment of soured milk—that is to say, milk, the sugar of which has undergone lactic fermentation. Clinically this condition may be associated either with constipation or the reverse. (Incidentally such cases do very well with a tablespoonful of raw oatmeal taken in the morning, owing to the fact that the starch granules are not broken up until they reach the lower bowel, where they furnish a pabulum upon which lactic acid organisms flourish abundantly.)

As the result of several years' observation in general practice, I think that the man who habitually has one well formed, possibly even rather hard motion daily, of good colour, is far more likely to be healthy—that is to say, to resist the ravages of chronic infections—than he who has two or three soft motions, and who probably prides himself on the fact. The latter is in all probability suffering to some extent from either carbohydrate or protein putrefaction, a condition which very slowly and insidiously will produce those changes associated in the lay press and in many minds with constipation. As the result of propaganda, and the diffusion of medical knowledge, there has already been evolved the type of person who tells one with pride of his two or three daily sacrifices to cloacina, and who expects to be cured quickly and kept alive to a green old age in consequence.

The evil-producing qualities of a stool depend far more upon a departure from normal of its bacterial content than upon its consistency or frequency, and in treating this particular function of the human body the help of the pathologist should more frequently be sought.—I am, Sir, yours faithfully,

Reading, Nov. 27th, 1924. **E. G. March.**

PATHOLOGY OF NEPHRITIS.

To the Editor of The Lancet.

Sir,—In the review appearing in your issue of Nov. 22nd of an article of mine in the October issue of the *Quarterly Journal of Medicine* I am credited with the statement that all my cases of nephritis "might, had not death intervened, have conformed to the chronic interstitial type." May I be permitted to point out that this is exactly what I did not state? Actually my communication took the form of an attempt to demonstrate the existence of two types of "chronic parenchymatous nephritis," one of which, barring accidents, tended to recovery, while the other proceeded inevitably to the "chronic interstitial" stage. I am, Sir, yours faithfully,

Wolverhampton, Nov. 29th, 1924. **S. C. Dyke.**

"A DISCLAIMER."

To the Editor of The Lancet.

Sir,—I have seen the letter from Dr. Knyvett Gordon, of the Virol Laboratories, under this heading in your issue of Nov. 22nd, and I have to say only that I could have wished that, for his own sake, he had not contented himself with quoting a single casual sentence from my letter, but had added that I began it with a frank apology and expression of regret if I had inadvertently omitted any usual courtesy in quoting him without previously asking his consent. The quotation itself clearly shows more than once that he favours vaccine-therapy, as opposed to chemo-therapy: and therefore I cannot believe that any ordinary reader of the pamphlet would gather an impression that Dr. Gordon could be by it associated with my own views on the employment of intestinal bactericides. My one and only object in quoting him was to show, as I said, that his expressed opinion "affords striking evidence of the influence of systemic infection in pyorrhœa."

In the same brief pamphlet I had occasion to quote Mr. Peyton Beale, Dr. Alexander Bryce, and Mr. Garnett Ellis; and I still cannot help feeling that I did pay, to at least some little extent, a real compliment to Dr. Gordon by placing him with these authorities. But my one complaint is that a solitary sentence should be torn out of my reply to his protest, and the ready expression of regret, and a promise to consult him in any future case, be omitted. Such a letter conveys a quite unfair impression. Of course, there are various standards of fairness in public controversy: Dr. Gordon has chosen his, and I must leave your readers to decide whether he has chosen well.

I am, Sir, yours faithfully,
J. T. Ainslie Walker, F.I.C., F.C.S.
Ludgate Hill, London, E.C., Nov. 25th, 1924.

To the Editor of The Lancet.

Sir,—I am obliged to you for letting me see Mr. Ainslie Walker's reply to my disclaimer. There was no point in reproducing the whole of his letter, so I quoted the sentence that mattered. It is true that Mr. Ainslie Walker stated that if he had inadvertently omitted any courtesy customary between scientific investigators he regretted and apologised, but he went on to justify his quotation from my article without my consent and even described that procedure as a compliment. I objected because the pamphlet was not a scientific publication but a commercial advertisement. The extract appeared in a pamphlet advocating dimol, and has, in fact, actually led to my being credited with thinking favourably of that drug when I happen not to do so.

The fact that other writers were so treated does not seem to me relevant.

I am, Sir, yours faithfully,
A. Knyvett Gordon, M.B., B.C., B.A. Camb.
Bedford-square, W.C., Nov. 29th, 1924.

INSUFFLATION OF THE FALLOPIAN TUBES.

To the Editor of The Lancet.

Sir,—My friend, Mr. Victor Bonney, is in error in supposing that the simple method—described in The Lancet, Nov. 22nd—which he has been using, apparently for a few months only, is new. I have employed this procedure since 1921; and I think I am right in saying that Dickinson and others in the United States have also long practised insufflation of the tubes in the same way.

The use of air has one disadvantage—namely, there is more and longer-continued pain subsequently than after insufflation with CO_2. I agree with Mr. Bonney that there are unsuspected lesions capable of producing sterility that can only be discovered by insufflation; but as I hope before long to publish in conjunction with some of my colleagues our experiences I shall not dwell on them here.

I am, Sir, yours faithfully,

Liverpool, Nov. 23rd, 1924. **W. Blair Bell.**

PITUITARY WHOLE GLAND IN CONSTIPATION.

To the Editor of The Lancet.

Sir,—Although experimental physiologists tell us that whole pituitary gland when administered to animals in the laboratory produces no effects, its clinical administration to human beings seems to be attended in many cases with well-marked results. In The Lancet of Oct. 18th Dr. Bernard Myers reported its successful clinical use in a case of chronic constipation, and I now record another case of chronic constipation similarly treated.

A. B., a healthy European male adult of about 30 years, had suffered for some years with chronic constipation. He led an active, vigorous life, and had tried most of the various known purgatives, including liquid extract of cascara sagrada, but had failed to secure permanent relief. On being consulted I surmised that the case might then be partly due to muscular atony of the bowel induced by chronic overloading (intestinal stasis). Being aware of the physiological action on the bowel of subcutaneous injections of extract of the posterior lobe of the pituitary gland, I determined to try the effect of the administration of whole gland substance by mouth—daily subcutaneous injections of pituitrin in such a case being out of the question. One tabloid of whole pituitary gland, gr. 2, was therefore prescribed t.i.d., and within two months the patient reported his condition cured.

This took place in the year 1913, and lapse of time has abundantly proved the cure to be permanent. Since then I have prescribed whole pituitary gland in several other such cases, and also in many cases of post-operative atony of the bowel with constipation, similarly successful results being achieved in all. In the nervous and physical exhaustion following operations I have also found whole pituitary gland of the greatest value. In India it is particularly useful in the mental and physical exhaustion produced by continuous residence in the plains during the hot season of the year.

I am, Sir, yours faithfully,
J. W. TOMB., M.D., D.P.H.

Asansol, Bengal, India, Nov. 12th, 1924.

INTRA-OCULAR TENSION IN MYOPIA.

To the Editor of THE LANCET.

SIR,—The conditions mentioned by Dr. J. Lawson Dick in your issue of Nov. 29th (p. 1151) are undoubtedly important contributory factors in the causation of myopia, but increased intra-ocular tension is the direct exciting cause, just as the tubercle bacillus is the direct exciting cause of tuberculosis. In the conditions mentioned by Dr. Dick it is particularly important to avoid all increase of intra-ocular tension which will obviously act more effectively with a weak eye than with a strong one. After the publication of my Arris and Gale lecture in THE LANCET I received numerous letters from ophthalmic surgeons in all parts of the world agreeing with my conclusions. What other explanation could be given of the following case? A man staying at a farm had to help to hold a bull which had become wild, and he had to exert his strength to the utmost; he ruptured himself, became myopic in a low degree in one eye and blind in the other through detachment of the retina, in the one afternoon; he stated that he had previously very good sight.

I am, Sir, yours faithfully,
F. W. EDRIDGE-GREEN.

London, Dec. 1st, 1924.

Obituary.

ROBERT JAMES LEE, M.D. CAMB.

Dr. Robert James Lee, at one time physician to the Hospital for Children, Great Ormond-street, died recently at the age of 83, at West Drayton. The son of Robert Lee, F.R.S., the famous obstetrician whose differences with the Royal Society caused much stir in their time, he received his early education at King's College School, London, and Brighton College, and went up to Gonville and Caius College, Cambridge, as a Tancred Student. He studied medicine at St. George's Hospital, St. Thomas's Hospital, and in Paris, becoming an M.D. Camb. in 1869 and a Fellow of the Royal College of Physicians of London in 1874, in which year he was appointed Goulstonian lecturer. His first appointment was as lecturer in pathology and forensic medicine at Westminster Hospital, and later he became joint lecturer in obstetric medicine and assistant obstetric physician at St. George's Hospital, taking for his subject in the Goulstonian lectures, Puerperal Fever. Dr. Lee was an early contributor to the columns of THE LANCET, following the precedent of his father, and many of the lectures he delivered to his students appeared in our pages. In 1873 he published a work on "Exercise and Training, their Effects upon Health," in which he distinguished two kinds of fatigue—local or muscular fatigue and general fatigue or loss of wind—and in which he gave some valuable hygienic rules to be observed while training. In 1876 appeared the "History, Diagnosis, and Treatment of Whooping-cough," and three years later he compiled a small text-book for students on pathological anatomy. In 1889 he published a series of lectures on the "Transmission of Syphilis from Parents to Offspring," which followed the publication of his lectures at the Great Ormond-street Sick Children's Hospital during the years 1884–5–6, and several of his papers on scientific and medical subjects are recorded in the Proceedings of the Royal Society and elsewhere.

Dr. Lee was an enthusiastic athlete, both on the running-track and as an oarsman. He never fulfilled his early promise, either as a general physician or a specialist, largely because he was distinctly difficult. He resigned his Fellowship of the Royal College of Physicians of London, and lived for many years in retirement.

Medical News.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

Honours.—Frank B. Byrom (*a*), London Hosp.; Lawrence Dulake (*b*, *d*, University Medal), King's Coll. Hosp.; John Angell James (*a*), University of Bristol; Richard J. Toleman (*a*), London Hosp.; and Mary M. Turnbull (*a*), King's Coll. Hosp.

(*a*) Distinguished in Medicine. (*b*) Distinguished in Pathology. (*d*) Distinguished in Surgery.

Pass.—Katharine M. Andrew, King's Coll. Hosp.; Ruth M. Arkwright, St. Mary's Hosp.; Nehemiah Asherson, Univ. Coll. Hosp.; Alfred A. Battson, St. Thomas's Hosp.; John Bevan-Jones and Phyllis E. Bond, Univ. Coll. Hosp.; Reginald T. Brain, London Hosp.; Violet W. Brown, St. Mary's Hosp.; Frank A. Bryning, King's Coll. Hosp.; Arthur B. Cooper and Edward R. Cullinan, St. Bart.'s Hosp.; William A. Date, St. Mary's Hosp.; David J. Davies, Middlesex Hosp.; Francis Davies, Univ. Coll. Hosp.; Iforwyn G. Davies, St. Bart.'s Hosp.; Arnold F. Doyle, St. Thomas's Hosp.; Ernest F. Duck, Doris L. Durie, and David G. M. Edwards, Univ. Coll. Hosp.; John Elgood, St. Bart.'s Hosp.; Phyllis V. L. Epps, London Sch. of Med. for Women; Stewart Farquharson, St. Thomas's Hosp.; Valentine F. Farr, St. Bart.'s Hosp.; Margery Freeborough, St. Mary's Hosp.; Horace P. Goldsmith and John A. E. M. Hadley, Univ. Coll. Hosp.; Ronald Hare, St. Mary's Hosp.; John K. Hasler, Middlesex Hosp.; Sybil M. Hawkes, London Sch. of Med. for Women; Kenneth W. Heritage, London Hosp.; Elfrida L. G. Hill, Univ. Coll. Hosp.; Frances A. Hogben, University of Manchester; Barbara M. Hope, King's Coll. Hosp.; Margaret Hossell, London Sch. of Med. for Women; Audrey M. Hughes, Charing Cross Hosp.; Cyrus Ive, Guy's Hosp.; Francis J. Jauch, London and Middlesex Hosps.; Arthur E. Jenkins, St. Thomas's Hosp.; Eva M. Johnson and Alan T. Jones, Univ. Coll. Hosp.; David J. Jones, Westminster Hosp.; John W. Joule, St. Bart.'s Hosp.; Nancy R. Lewis, London Sch. of Med. for Women and St. Mary's Hosp.; Kate Madders, Harold J. Malkin, and Doris I. Mart, Univ. Coll. Hosp.; Violet E. M. Mizen, London Sch. of Med. for Women; Paul McG. Moffatt, Guy's Hosp.; Herbert V. Morlock, St. Bart.'s Hosp.; Arthur D. Morris and Herman Mould, Univ. Coll. Hosp.; Alfred L. te W. Naudé, St. Thomas's Hosp.; Frederick G. Nicholas, Middlesex Hosp.; Doris E. O'Doherty, London Sch. of Med. for Women; Patrick H. O'Donovan, London Hosp.; Cyril M. Pearce, St. Bart.'s Hosp.; John P. Peel, University of Leeds; Abraham T. W. Powell, Guy's Hosp.; Cyril S. C. Prance, St. Bart.'s Hosp.; Violet A. Quilley, London Sch. of Med. for Women; William A. Robb, St. Bart.'s Hosp.; Nina L. D. Robertson, King's Coll. Hosp.; Morris Rockfelt, Winifred M. Sampson, and Margaret B. Savory, Univ. Coll. Hosp.; George D. Shaw, Guy's Hosp.; Norman W. Snell, King's Coll. Hosp.; Dorothy M. Stewart, London Sch. of Med. for Women and St. Mary's Hosp.; Grace M. L. Summerhayes, London Sch. of Med. for Women; Dick B. Sutton, King's Coll. Hosp.; Mary A. St. Clair Swann, London Sch. of Med. for Women; Harry C. C. Taylor, Guy's Hosp.; Portia K. Taylor and Robert C. Taylor, Univ. Coll. Hosp.; Beatrice Teverson, St. Mary's Hosp.; Douglas J. Valentine, London Hosp.; Arthur H. C. Visick, St. Bart.'s Hosp.; and Henry G. Wyatt, London Hosp.

A course of three lectures on The Anatomy and Physiology of the Sympathetic Innervation of the Striated Muscle will be given at University College, by Prof. John Irvine Hunter, of the University of Sydney, at 5 P.M., on Dec. 8th, 10th, and 12th. At the first lecture the chair will be taken by Prof. G. Elliot Smith F.R.S. Admission to these lectures is free.

UNIVERSITY OF EDINBURGH.—The following candidates were successful in the recent Clinical Examination for the degree of M.D. :—

Hope P. Anderson, John Bennet, Jessie R. Brash, James D. S. Cameron, Angus H. Campbell, Sisir C. Chatterjee, John A. Douglas, Alexander D. Edington, William R. D. Fairbairn, Helen M. Hendrie, Frederick T. Ingram, Alan J. Kilgour, Ella MacKenzie, Ronald D. Mackenzie, William F. Mair, David Pottinger, Hilda D. Scott, Doreen Stranger, Thomas R. R. Todd, Edward R. C. Walker, William N. Boog Watson, J. H. Harley Williams, Alexander B. Williamson, and William M. Wilson.

OLD EPSOMIAN CLUB.—The annual dinner of the club will be held at the Trocadero Restaurant, Piccadilly Circus, on Thursday, Dec. 11th, at 7.15 P.M. Mr. George E. Waugh will be in the chair. The annual meeting will precede the dinner at the same place at 6.30 P.M. Members of the club intending to be present at the dinner are asked to notify Mr. R. M. Handfield-Jones, 53, Hamilton-terrace, St. John's Wood, N.W. 8, as soon as possible, mentioning the names of those near whom they would like to sit. The price of the dinner is 8*s.* 6*d.* (exclusive of wine), and will be collected at the table.

ROYAL SANITARY INSTITUTE: HENRY SAXON SNELL PRIZE.—The subject given for essays in competition for this prize in 1924 was Improvements in the Sanitary Conditions of Underground Dwellings and Small Underground Workshops. Eleven essays were received, including one from Canada, and they have been brought under the consideration of the Council. Acting on the advice of the adjudicators, the Council have awarded the prize of 50 guineas and the silver medal of the Institute to Mr. E. Thomas Swinson, M.R.San.I. (Feltham). Two of the other essays showed considerable merit, and the Council have decided to recognise this by making a supplementary award of a bronze medal of the Institute to each of the writers, Mr. Edward E. Barks, A.R.I.B.A. (London) and Mr. F. R. Jelley (Sutton).

MANCHESTER HOSPITAL SUNDAY FUND.—At the annual meeting of the Manchester and Salford Medical Charities the report presented showed that the income of the Sunday Fund was £14,029, the interest from investments £1275, and the amount distributed to charities £13,649. The Shrove Tuesday collections of the University students showed a persistent and satisfactory increase. In 1921 the students collected £656; in 1922, £1036; in 1923, £2017; and in 1924, £2850. Outside areas for the most part only contributed £1 out of every £2 which Manchester and Salford hospitals spent in treating outside area patients. In 1923 the number of cases treated in institutions of the Manchester and Salford Medical Charities was 295,718, at a cost of £335,591, while the ordinary income fell about £44,000 short of that expenditure.

UNIVERSITY OF LIVERPOOL.—Some interesting statements were made at the annual November meeting of the Court of the University of Liverpool. The number of students and the expenditure of the University have doubled during the past ten years, and additional financial support is required and imperative if the work is not to be crippled. On an average the fees paid by the students covered only one-third of the cost. The budget for 1914 showed an expenditure of £80,000, whereas to-day it is £197,000, and there is a debt to the bank of £57,000. In 1914 the number of full-time students was about 900; to-day it was 1700, notwithstanding the fact that practically all the ex-Service students had departed. Vice-Chancellor Adami in his report called attention to some "live problems." At the present time, he said, there was not a sufficiency of posts in industry to employ even half the graduates in chemistry of the last two years, while many newly graduated women doctors throughout the country were seeking in vain for hospital appointments. The annual deficit in the working of the University is between £6000 and £7000.

DONATIONS AND BEQUESTS.—By the will of the late Mr. J. H. Morgan, F.R.C.S., the testator left among other bequests £1000 to Charing Cross Hospital; £250 to the Hospital for Sick Children, Great Ormond-street, W.C.; £200 to the British Medical Benevolent Fund; and £100 to Lord Mayor Treloar's Hospital at Alton.—Mr. Walter Jones, of Stourbridge, left £1000 each to the Corbett Hospital, Amblecote, Stourbridge, Dr. Barnardo's Homes, to certain trusts as to land recently presented to him at Stourbridge, and to the trustees of the British Healers' Association, Manchester.—Mr. David Islip, retired fish-curer, of Hull, left (subject to a life-interest) £1500 to Hull Royal Infirmary for the endowment of a bed in the Walker Ward in memory of his late wife; £500 each to the Hull Seamen's and General Orphan Asylum, Kingston-on-Hull, and to the Port of Hull Society's Sailors' Orphan Home; £250 to the Victoria Hospital for Sick Children, Kingston-on-Hull; £100 to the Hull and Sculcoates Dispensary; and £50 to the Hull Blind Institution. After other bequests, the ultimate residue of the property is left in equal shares to the Hull Royal Infirmary and the Hull Seamen's and General Orphan Asylum.—Coalville Urban Council have accepted a gift of £8000 from the Leicestershire Miners' Welfare Committee towards the provision of public baths in the town.—Miss Emily Sarah Soden Philpot, of Penge, left nearly £20,000 to charity. She bequeathed £500 each to the London, Guy's, Charing Cross, St. Bartholomew's, and Middlesex Hospitals; £500 each to the Metropolitan and City Police Orphanage; £250 each to the Hospital for Sick Children, Great Ormond-street, the South-Eastern Hospital for Children, Sydenham, the Beckenham and Norwood Cottage Hospitals, and the Convent for Sisters of Nazareth, Hammersmith; and £105 to Dr. Harding Philipps. After further legacies, she left all her other property equally between eight charitable institutions.—The Royal Northern Hospital has received from the executors of the late Miss Mary Neal, of Victoria-road, Southborough Common, Kent, a cheque for £4678 13*s.* 11*d.* This sum is to be divided equally between the Royal Northern Hospital, Holloway, and the Royal Chest Hospital, City-road.—Mr. Geoffrey Duveen, who has already munificently contributed to schemes for medical education in the University of London, has given £50,000 to University College for the construction of a new Ear, Nose, and Throat Hospital to perpetuate the memory of his late father. It will be remembered that last year Mr. Duveen gave £15,000 for the purpose of providing a suitable site adjoining University College Rockefeller buildings in Huntley-street, and £10,000 to the University of London for the establishment and endowment of a chair of Otology.

COLONIAL MEDICAL COUNCIL AT CAPE TOWN.—At the monthly meeting of the Colonial Medical Council, held at Cape Town on Tuesday, Nov. 4th, Dr. Darley Hartley presiding, the resolution passed at the last previous meeting recognising the medical degrees conferred by the University of Cape Town was unanimously confirmed. It was resolved to hold the examinations for midwifery certificates in the middle of December. It was stated that 48 candidates would sit, of whom 34 would be from the Cape. A communication was read from the executive of the South African Native College at Fort Hare asking to be favoured with a suitable curriculum for a proposed medical course for native students. The Chairman thought that, as the Council was only concerned with the registration of degrees and diplomas, it was outside of its province to give the desired advice. He thought that the reply should be given by the Universities, who were the qualifying bodies. It was resolved to reply that the question of a suitable curriculum could be more advantageously answered by the University to which the College is affiliated.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Dec. 8th.

WAR: at 5 P.M.

Paper:

Major R. W. G. Hingston, M.C., I.M.S.: Some Observations on the Application of the Royal Air Force Physical Efficiency Test in the 1924 Mount Everest Expedition.

Tuesday, Dec. 9th.

THERAPEUTICS AND PHARMACOLOGY: at 4.30 P.M.

Paper:

Prof. W. E. Dixon and Dr. F. H. A. Marshall: The Influence of the Ovary on Parturition.

OBSTETRICS AND GYNÆCOLOGY.

Members of this Section are particularly invited to be present and to join in the Discussion.

PSYCHIATRY: at 8.30 P.M.

Paper:

Dr. David Orr: The Anatomical and Physiological Mechanism of Emotion.

Wednesday, Dec. 10th.

MEDICINE
OTOLOGY
NEUROLOGY
LARYNGOLOGY } at 5.10 P.M. (to be adjourned, if necessary, to 8 P.M.).

Joint Discussion on
The Causes, Early Recognition, and Treatment of Non-Tubercular Meningitis.

Openers :
Dr. Hugh Thursfield (Section of Medicine).
Sir William Milligan (Section of Otology).
Dr. Worster-Drought and Dr. J. G. Greenfield (Section of Neurology).
Mr. W. M. Mollison (Section of Laryngology).

Thursday, Dec. 11th.

TROPICAL DISEASES AND PARASITOLOGY : at 5.30 P.M.

Paper :
Mr. J. Ramsbottom : Edible and Poisonous Toadstools (illustrated by coloured lantern slides).
A cinematograph film illustrating the Biology of Bilharzia, kindly lent by Dr. W. Watkins-Pitchford, will be shown by kind permission of the South African Institute for Medical Research, Johannesburg.

Exhibits :
Dr. H. B. Day : (*a*) Charts showing the Effect of Antimony Tartrate on Bilharzia Ova ; (*b*) Coloured drawing showing Effect of Antimony Tartrate on Bilharzic Urine.
Lieut.-Colonel H. Marrian Perry, R.A.M.C. : The Life-history of the Water Snail.

COMPARATIVE MEDICINE
THERAPEUTICS AND PHARMACOLOGY } Members of these Sections are cordially invited to attend this meeting.

NEUROLOGY : at 8 P.M.

Clinical Meeting at the West End Hospital for Nervous Diseases, Welbeck-street, W.

Notes of cases (as concise as possible and in a form suitable for publication) should be sent to the Junior Hon. Secretary (Dr. Feiling) not later than the first post on Monday, Dec. 8th.

Friday, Dec. 12th.

CLINICAL : at 5.30 P.M. (Cases at 5 P.M.)

Cases :
Mr. G. A. Rutherford : Two Cases of Purpura Hæmorrhagica, treated by Splenectomy, and one case awaiting treatment.
Sir Percy Bassett-Smith : Case of Pituitary Tumour.
Dr. Parsons-Smith : Two Cases of Cardiac Disease.
Other cases will be shown.

OPHTHALMOLOGY : at 5 P.M.

Clinical Meeting at the Royal Westminster Ophthalmic Hospital, King William-street, Strand.
A Discussion on the Cases shown will take place at 6 P.M.

ANÆSTHETICS : at 8.30 P.M.

Discussion on
Splanchnic Analgesia with Record of Cases.
Mr. O. Stanley Hillman will speak on Technique and the Surgical Aspect.
Mr. Raymond E. Apperly will deal with the Anæsthetic Aspect.

SURGERY :
Members of this Section are specially invited to attend this Discussion.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

Monday, Dec. 8th.—8.30 P.M., Discussion on the Present Position of the Treatment of Diabetes by Insulin, to be introduced by Dr. George Graham, followed by Prof. MacLean and others.

HARVEIAN SOCIETY OF LONDON.

Thursday, Dec. 11th.—8.30 P.M. (at Paddington Town Hall, Harrow-road, Paddington Green). Dr. Charles Buttar : The Future Position of Consultants under the National Insurance Act. To be followed by a discussion.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, W.

Thursday, Dec. 11th.—8.15 P.M., Discussion on Some Clinical and Scientific Aspects of Drug Addiction in the Tropics, opened by Prof. Dixon, F.R.S., of Cambridge, and Sir Havelock Charles, followed by Sir William Collins and Dr. Arthur Powell. Preceded by a Demonstration at 7.45 P.M.

WEST KENT MEDICO-CHIRURGICAL SOCIETY, Miller General Hospital, Greenwich, S.E.

Friday, Dec. 12th.—8.45 P.M., Mr. Bellingham G. Smith : The Importance of the Antenatal Clinic (Purvis Oration). There will be a conversazione and Mr. F. Davidson will give a demonstration of the Super-microscope with lantern slides.

BIOCHEMICAL SOCIETY (Biochemical Laboratory, Imperial College of Science and Technology, South Kensington).

Monday, Dec. 8th.—5 P.M., E. Watchorn : The Magnesium of Human Serum. M. E. Robinson and R. A. McCance : The Oxidation of Amino-acids by Fungus Tyrosinase. H. W. Buston, H. N. Mukherjee, and S. B. Schryver : The Isolation of a Hydrolysis Product of the Proteins, Hitherto Undescribed. H. Martin and S. B. Schryver: Some Transformations of Casein. Dorothy Griffiths and S. B. Schryver : The Separation of the Proteins of Egg-white in an Electrical Field.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Dec. 8th, to Saturday, Dec. 13th.—West Lecture Hall, Royal Society of Medicine. Lecture arranged by the Fellowship of Medicine and open to all members of the profession. At 5.30 P.M. Wed., Dec. 10th, Mr. James Berry : Cancer of the Thyroid.—Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E. Special Course in Medicine, Surgery, and Gynæcology. Lecture-Demonstrations in the Wards and Out-patient Departments. Infants Hospital, Vincent-square, S.W. Special Course in Diseases of Infants, consisting of clinical demonstrations, " Round Table " consultations, lectures, &c.—Hospital for Diseases of the Skin, Blackfriars-road. Course in Dermatology, consisting of instruction in Out-patient Department every afternoon at 2.30 P.M., and a Venereal Clinic Tuesdays and Fridays.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday.—12 noon, Mr. Simmonds : Applied Anatomy. 2 P.M., Mr. Addison : Surgical Wards. 2 P.M., Dr. Scott Pinchin : Medical Out-patients.

Tuesday.—11 A.M., Dr. McDougal : Electrical Dept. 12 noon, Dr. Burrell : Chest Cases. 2.30 P.M., Mr. Tyrrell Gray : Surgical Wards.

Wednesday.—12.15 P.M., Dr. Burnford : Medical Pathology. 2 P.M., Dr. Owen : Medical Out-patients. 2.30 P.M., Mr. Donald Armour : Surgical Wards.

Thursday.—10 A.M., Dr. Grainger Stewart : Neurological Dept. 11 A.M., Mr. Simson : Gynæcological Wards. 2 P.M., Mr. MacDonald : Genito-Urinary Dept.

Friday.—10.30 A.M., Dr. Pritchard : Medical Wards. 12 noon, Surgical Registrar : Surgical Pathology. 2 P.M., Mr. Vlasto : Throat, Nose, and Ear Dept.

Saturday.—9.30 A.M., Dr. Burnford : Bacterial Therapy 10 A.M., Dr. Saunders : Medical Diseases of Children. 10 A.M., Mr. Banks-Davis : Throat, Nose, and Ear Operations.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Tuesday, Dec. 9th.—4.30 P.M., Mr. C. H. Hayton : Quinsies, their Complications and Treatment.

Friday.—4.30 P.M., Mr. W. Ibbotson : Nasal Sinusitis, its Importance, Diagnosis, and Treatment.

Daily : Medical and Surgical Clinics, Clinics in the various Special Departments, Surgical Operations, &c.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, Dec. 11th.—4 P.M., Dr. Thursfield : Splenomegaly.

ROYAL DENTAL HOSPITAL OF LONDON POST-GRADUATE LECTURES.

Wednesday, Dec. 10th.—5 P.M., Mr. H. Stobie : Diagnosis and Surgical Principles Underlying Treatment of Cysts and Other Common Tumours of the Jaws.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.

Tuesday, Dec. 9th.—5 P.M., Dr. J. H. Sequeira : Tuberculosis Cutis.

Thursday.—5 P.M., Dr. S. E. Dore : Erythemato-squamous Eruptions.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

Tuesday, Dec. 9th.—4.15 P.M., Dr. F. Craven Moore : Some Aspects of *Bacillus coli* Infection.

Friday.—Dr. D. E. Core : Early Mental Disease, its Differentiation and Prognosis.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES. (At 3.30 P.M.)

Tuesday, Dec. 9th.—(At the Royal Infirmary.) Mr. R. St. L. Brockman : The Complications of Gall-stones.

Friday.—(At the Royal Hospital.) Mr. Garrick Wilson : Acute Osteomyelitis.

BRISTOL UNIVERSITY POST-GRADUATE DEMONSTRATIONS.

Wednesday, Dec. 10th.—3.15 P.M. (at the Town Club, Swindon), Dr. A. T. Todd : Hepatic Insufficiency, Diagnosis, &c.

ST. ANDREWS INSTITUTE FOR CLINICAL RESEARCH.

Tuesday, Dec. 9th.—4 P.M., Dr. Maclennan : Clinical Pathology of the Urine.

INSTITUTE OF HYGIENE, Devonshire-street, W.

WEDNESDAY, Dec. 10th.—3.30 P.M., Dr. A. Middleton Hewat: Infant Foods and Feeding.

ROYAL INSTITUTE OF PUBLIC HEALTH, Russell-sq., W.C.
(Course of Lectures on the Health of the Commonwealth.)

WEDNESDAY, Dec. 10th.—4 P.M., Sir Robert Jones: The Problem of the Cripple Child.

THE PEOPLE'S LEAGUE OF HEALTH. Course of Lectures on the Mind and What We Ought to Know About It.
(At the Medical Society of London, 11, Chandos-street, W.)

MONDAY, Dec. 8th.—6 P.M., Dr. Tredgold: Mental Deficiency.

Appointments.

HODSON, V. S., M.B. Oxf., M.R.C.P. Lond., has been appointed Physician to Out-patients at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.

MCILROY, A. LOUISE, M.D., D.Sc. Glasg., Examiner in Obstetrics in the University of London.

Manchester Royal Infirmary: SMITH, G. S., M.B., Ch.B. Manch., House Surgeon; ROBERTS, W. M., M.B., Ch.B. Manch., House Physician; HORTON, W. L., M.B., Ch.B., Clinical Assistant.

St. Mary's Hospitals, Manchester: ROBINSON, G. T., M.B., Ch.B. Manch., COWAN, J. MUIR, M.B., Ch.B. Manch,, and WILDE, J. MARGARET, M.B., Ch.B. Manch., House Surgeons.

Vacancies.

For further information refer to the advertisement columns.

Belgrave Hospital for Children, Clapham-road, S.W.—Res. M.O. at rate of £100.

Birkenhead Borough Hospital.—Sen. H.S. £200.

Birmingham, Queen's Hospital.—Pathologist. £100.

Bristol Royal Infirmary.—Hon. Reg. to Ear, Nose, and Throat Dept.

Buxton, Derbyshire Devonshire Hospital.—Asst. H.P. at rate of £150.

Cambridge, Addenbrooke's Hospital.—Cas. O. and Res. Anæsthetist at rate of £130.

Charing Cross Hospital, W.C.—Res. M.O. £400.

Chelmsford Administrative County of Essex.—Two Asst. County M.O.H.'s. Each £600.

Derbyshire Royal Infirmary.—Hon. Asst. S. Also Ophthal. H.S. £200.

Doncaster Royal Infirmary.—H.P. £150.

Douglas, Isle of Man, Noble's Hospital.—Res. H.S. £175.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—H.S. at rate of £125.

East Sussex County Mental Hospital, Hellingly, Sussex.—Pathologist. £400.

Exminster, Devon Mental Hospital.—Jun. A.M.O. £300.

Greenwich, Dreadnought Hospital.—H.P. and H.S. at rate of £150.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Hon. Ophth. S.

Infants Hospital, Vincent-square, Westminster.—Jun. Anæsthetist.

Ipswich, East Suffolk and Ipswich Hospital.—H.P. £100.

Johannesburg, South African Inst. for Med. Research.—Plague Bacteriologist. £1500.

Leeds Maternity Hospital.—University Tutor in Obstetrics, &c. £300.

London Hospital, E.—First Asst. to Medical Firm. £400.

London Lock Hospital, 91, Dean-street, W.—Clin. Asstships.

London Lock Hospital, 283, Harrow-road, W.—Second H.S. £150.

Malayan Medical Service.—Medical and Health Officers. See advt. for salaries.

Manchester Royal Infirmary.—R.M.O. £200.

Middlesex Hospital, W.—Sen. Asst. Radiologist. £500. Two Asst. Radiologists. Each £160. Radium Officer. £300, and Dental H.S. £50.

National Dental Hospital, Great Portland-street, W.—Hon. Anæsthetist.

Oldham Royal Infirmary.—H.S.'s. Each £200.

Queen Mary's Hospital, Stratford, E.—Res. M.O., H.P., two H.S.'s Obstet. H.S., and H.P. and Cas. O. Hon. Asst. P. Also Clin. Asst. to Throat, Nose, and Ear Dept.

Rainhill, Lancs County Mental Hospital.—Temp. Asst. M.O. 7 guineas weekly.

Reading, Royal Berkshire Hospital.—Third H.S., H.P., and first H.S. All at rate of £150.

Royal Army Medical Corps.—Commissions.

Royal College of Physicians, Pall Mall East.—Milroy Lecturer.

Royal Masonic Institution for Girls, Clapham Junction.—M.O. £350.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Cas. O. £150.

St. Mary's Hospital, W.—Med. Reg. £200. Med. Supt. £400.

St. Peter's Hospital for Stone, &c., Covent Garden, W.C.—Clin. Assts.

Salford Royal Hospital.—Res. M.O. and H.P. at rate of £175 and £125 respectively.

Sheffield Royal Infirmary.—H.S., Asst. Cas. O. and Asst. Ophth. H.S. Each £60.

Southampton, Royal South Hants and Southampton Hospital.—Sen. H.S. £200.

Southwark Hospital, East Dulwich Grove, S.E.—Two Asst. M.O.'s. Each £300.

Staffordshire General Infirmary, Stafford.—H.P. at rate of £150.

Swansea General and Eye Hospital.—H.S. £175.

West Bromwich and District Hospital.—Res. Asst. H.S. £180.

Western Dispensary, 38, Rochester-row, Westminster, S.W.—Resident. £100.

West Ham County Borough.—Tuberculosis O. £900.

West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S. and Res. Cas. O. Each at rate of £100.

Winchester, Hampshire County Council.—Asst. M.O.H. £600.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Chester-le-Street, Durham; and Camborne, Cornwall.

Births, Marriages, and Deaths.

BIRTHS.

CUNNINGHAM.—On Nov. 24th, at Chesham, Bucks, the wife of F. H. Lester Cunningham, M.C., M.B., B.S., of a daughter.

GALBRAITH.—On Oct. 28th, at St. Stephens, Launceston, the wife of Douglas H. A. Galbraith, M.C., M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

VELLUOT—LAWLOR.—On Nov. 12th, at Hong-Kong Cathedral, George Albert Velluot, M.B. Edin., M.D. Paris, Croix de Guerre, of Shanghai, to Alice Elizabeth, B.A., M.B., Med. Schol. T.C. Dub., eldest daughter of Mr. H. C. Lawlor, M.A., M.R.I.A., Belfast.

WOOD—CAMPBELL.—On Nov. 29th, at The Charterhouse Chapel, Guy Wood, M.B., M.R.C.P., of The Charterhouse, London, to Margaret, daughter of Mr. and Mrs. Archibald Campbell, of Wolseley-road, N.

DEATHS.

BENSON.—On Nov. 25th, suddenly, at his residence, The Elms, Steeple Claydon, Bucks, Philip Lambert Benson, M.A., M.D., D.P.H., J.P., aged 73.

REYNOLDS.—On Nov. 25th, at Twyford Abbey, Willesden, Ernest James Reynolds, M.R.C.S., &c.

ROBSON.—On Nov. 28th, at "Stow Thorna," Guildford, John Robson, M.D., F.R.C.S.E., in his 82nd year.

STEWART.—On Nov. 24th, at Starborough House, Bilton-road, Rugby, Percy Peter James Stewart, F.R.C.S. Edin., O.B.E.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE VALUE OF THE REFLEXES IN DIAGNOSIS.

Abstract of a Paper read before the West Kent Medico-Chirurgical Society on Nov. 14th, 1924,

BY J. S. RISIEN RUSSELL, M.D., F.R.C.P.,
PHYSICIAN TO THE NATIONAL HOSPITAL FOR NERVOUS DISEASES, QUEEN-SQUARE.

WHILE having no hesitation in selecting the reflexes, to the exclusion of every other method of clinical investigation, as the best means of arriving at a diagnosis of an affection of the nervous system, I am unable, with the same alacrity, to say on which of them I should rely most to the exclusion of the others, for the reason that they play such different rôles in the clinical picture of different disorders of the nervous system. For instance, what more important evidence of an organic affection than the pupil that fails to act reflexly to light and yet reacts on accommodation, but how limited is its application as compared with the large number of cases in which alteration of the plantar reflex from the normal flexor type to the extensor (Babinski's sign) serves us in diagnosis! If, however, we recognise that in the diagnosis of certain affections one reflex has a greater value than another, and that there must of necessity be exceptions in which the plantar reflex cannot compete with certain others in importance, it must be conceded that it affords the most valuable aid to diagnosis because of its applicability to so wide a range of cases.

Symptoms Real or Feigned.

I have only encountered one malingerer—and he well versed in every possible deception—who made use of the abnormal type of plantar reflex as part of the cleverly constructed clinical picture he presented, other parts of which, that concern our subject, being a fixed pupil that did not respond to light and absence of the conjunctival reflex on the same side. In all other cases of the kind in which assistance could be expected from it in attempts to defeat the malingerer the plantar reflex has never failed me.

A fit is, of course, one of the devices of the malingerer, and it also not infrequently happens that it becomes necessary to decide whether a fit is hysterical or truly epileptic. No real difficulty may present itself if one has the opportunity of observing the individual in the actual attack, but how seldom this happens. As a rule it is necessary for us to arrive at our conclusions from hearsay, and from an examination of the person after the attack is over. The state of the pupils and the conjunctival reflex, that are so important if we are fortunate enough to find the person actually in an attack, are no longer of any assistance, as the normal reflex response to light and to tactile stimulation may then be obtained, and yet the attack may have been one of true epilepsy. It is to other reflexes that we must turn our attention if we are to obtain any information from this source in attempting to arrive at a correct conclusion. The state of the knee-jerks, and the presence or absence of ankle-clonus should engage our attention, although all such manifestations are so fleeting that we may gain no valuable information from them, and yet do so from the state of the plantar reflex. So evanescent are all these phenomena, however, that I can recall only one instance in which I was able to demonstrate to a class all the phenomena that allowed of a positive diagnosis of epilepsy as opposed to hysteria or malingering. In this case the patient was brought in from the street in a fit, and reached the out-patient room in time for me to demonstrate that the knee-jerks were absent, that on their return they quickly became exaggerated and associated with ankle-clonus, while of the other abnormal phenomena present the extensor type of plantar reflex (Babinski's sign) was the last reliable sign to disappear and be replaced by the normal flexor response. I say reliable in that mere exaggerated knee-jerks which still obtained without ankle-clonus, or the abnormal type of plantar reflex, proved nothing. So transitory are these manifestations that no time should be lost in searching for evidence in these directions when confronted with a case in which the nature of a fit has to be decided.

Disease Functional or Organic.

Of the numberless cases in which the plantar reflex has proved invaluable in deciding between functional and organic nervous affections, two women, both of whom are dead, must serve in illustration. Both of these patients were submitted to me as cases of neurasthenia, and in neither of them could I find evidence to the contrary, except that they both revealed the abnormal type of plantar reflex on one side. One of these patients subsequently proved to be suffering from disseminated sclerosis, while in the other the disease which was commencing and which rapidly resulted in the death of the patient was what is known as subacute combined degeneration of the spinal cord. Both of these cases serve to remind us that not only does this abnormal phenomenon prove the existence of organic disease of the nervous system, but that it goes further and supplies us with the definite information that the central as opposed to the peripheral nervous system is at fault, and that, whether alone or in conjunction with other parts, the pyramidal system is involved in the morbid process.

Location Central or Peripheral.

The following case supplies an example of how the plantar reflex serves to determine the existence of central as opposed to peripheral affection, and of how it allows of the exclusion of one central disease of the nervous system as contrasted with another. A woman whose medical man sent her with a history of alcoholic excess and loss of power in her lower limbs, presented an appearance which confirmed the history of alcoholism. Her knee-jerks were absent, so that multiple peripheral neuritis, already suggested as probable by the history, was made all the more likely. Tabes has, however, to be borne in mind in any case in which the knee-jerks are absent, in spite of the person being alcoholic. The fact that the pupils reacted normally to light supported the probability of peripheral neuritis as opposed to tabes, a view strengthened by some tenderness elicited on squeezing the patient's calves. Certain as this diagnosis now appeared, however, it had to be considerably modified when it was found that the plantar reflex was of the extensor type, indicating that, however great a part alcoholic neuritis played in the production of the clinical picture, there must be central disease to account for the behaviour of the plantar reflex. A more detailed examination of the patient, including examination of the blood, established the diagnosis of subacute combined degeneration of the cord, which was confirmed not only by the subsequent clinical course of the patient's illness ending in death, but by the post-mortem and the microscopical examination of the spinal cord.

There is one aspect of the plantar reflex that calls for our attention, but which is overshadowed by Babinski's sign, and whose importance is, therefore, liable to be overlooked. I refer to its absence in functional cases in so far as response in the toes is concerned. This behaviour of the plantar reflex does not receive the attention it deserves. I would especially direct your attention to the possibility of its proving of assistance in some cases of accidents in which there is no evidence of structural damage to the nervous system, but only such functional manifestations as can be ascribed to shock. The case of a girl who received a blow on the back in an accident, and who, as a result, suffered from functional paraplegia for a time, will serve in illustration. She subsequently became able to walk, but continued to complain of pain in her back which incapacitated her and made walking difficult. Contrary to the oft-quoted statement that these patients recover as soon as they succeed in their legal action and receive monetary compensation, this girl continued an invalid, incapacitated and unable to earn her livelihood for a long time after, in accordance with what I expected would prove the case, as with exaggerated knee-jerks her plantar reflexes were absent. They were not of the abnormal extensor type which would have been evidence of structural damage to the spinal cord, nor were there concomitant signs to support a lesion of the nerve-roots or cauda equina and account for the absence of response on stroking the soles of the feet, the behaviour of the reflexes being clearly to be ascribed to functional disturbance. There could be no doubt that, no matter how much the girl might be consciously or unconsciously exaggerating her symptoms, a genuine substratum was present which justified the opinion formed and the prognosis given.

Result or Not of Accident.

It is necessary to consider the reflexes in their relation to accidents from another standpoint, however, the importance of which is well illustrated by two cases, in both of which tabes happened to be the organic disease present in the individuals who had met with the accidents. The first of the cases presented little difficulty, as the nature of the accident—a fall on the back when alighting from a tram-car that commenced to move forward before he was properly clear of it—scarcely provided material to account for absence of the knee-jerks in a man in whom there was no actual paralysis; while, even if this were disputed, it could scarcely be argued with any show of reason that pupils which acted on accommodation but failed to respond to light revealed a defect that could be ascribed to the accident in question. The pupil reflex was equally to be relied on in the evidence it supplied in the other case to which I wish to refer, but in which, otherwise, the case was not so easily disposed of. It so happened that, in addition to a blow on the back, both lower limbs received injuries, and while those to the one limb could not possibly be held responsible for any alteration of the reflexes, it was otherwise in the other limb where some injury to the sciatic nerve might well have resulted, such as could account for loss of the ankle-jerk which was found present. But the ankle-jerk of the other limb was also absent, although the injuries to it could not possibly be regarded as affecting the sciatic nerve. Moreover, the plantar reflex on both sides remained unaffected, as would have been impossible had there been damage to the sciatic nerve sufficient in degree to abolish the ankle-jerk. Doubts were dispelled by the behaviour of the pupils, one of which failed to react to light, while the reaction was very poor in the other. I may perhaps be excused for reminding you that in a case of tabes the ankle-jerks may be absent when the knee-jerks are still present or vice versa, for in this case, contrary to what you might have expected, the knee-jerks were both present, indeed, unduly active, a state of things to be ascribed to the more general effects of the shock to the nervous system occasioned by the accident.

Relative Value of Certain Reflexes.

While it has been impossible to avoid giving first consideration to the plantar reflex, this must not be taken to derogate from the importance of the evidence to be derived from investigation of the knee-jerks. On approaching this subject, however, we are at once confronted with the question as to whether or not the knee-jerk is ever truly absent in a normal person, or whether, when not elicited, this is to be regarded as evidence of disease. All that need be said is that if it be true that there are people, otherwise normal, whose knee-jerks are truly absent, such cases must be sufficiently rare that they ought not to be allowed to invalidate the rule that absence of knee-jerks is to be taken as indicating in all probability the existence of organic disease. Far be it from me to assert that the knee-jerks are never absent in people otherwise normal, but one is, I think, justified in refusing to accept any such case without the opportunity of a personal examination, for the reason that many a patient comes to me without knee-jerks and has them restored to him before he leaves. This leads me to remind you that there are many fallacies open in attempts to elicit the knee-jerks, and that there are right and wrong ways of trying to bring reinforcement to the aid of the observer who is attempting to elicit the knee-jerk with its assistance. This being the case, no case should be diagnosed as one of organic disease on the evidence supplied by the knee-jerks alone, but with this phenomenon as possible evidence of organic disease, some other unequivocal physical sign in confirmation should be sought, and if discovered then, and only then, should so grave a sentence be passed on the individual under suspicion.

Important as the ankle-jerk may prove in the diagnosis of tabes, it plays but a secondary part to that of the knee-jerk, which is so usually absent when the patient comes under observation as to make it the exception that we find it necessary to fall back on the ankle-jerk for assistance in attempting to arrive at a diagnosis owing to the knee-jerk being still present. Although exceptional, such cases do, however, occur in which, without the assistance of the ankle-jerk, a positive diagnosis might not be possible, indeed, even an erroneous opinion might be formed.

In thus according priority to the knee-jerks, it must not be supposed that the ankle-jerk may not in its turn claim preferment, for it may even prove to be of greater diagnostic value than the knee-jerk. Indeed, so much may it dominate the situation that it is not a question as to whether it is more often of service than the knee-jerk in this particular class of case, but rather that it is always of service, while the knee-jerk can only call for attention from a negative standpoint. In any case in which there is affection of the sciatic nerve, or of the nerve strands which enter into its formation, the ankle-jerk is of supreme importance in diagnosis. One of the cases last referred to makes it evident that the behaviour of the ankle-jerk is all important in an affection of the sciatic nerve. In the ordinary routine of practice "sciatica" is naturally a common affection, but all cases of pain referred to the distribution of the sciatic nerve are not necessarily "sciatica." The state of the ankle-jerk supplies evidence as to whether the condition is purely functional or whether it has an organic basis, for in the former the ankle-jerk remains active, or even too active, while in the latter, provided the morbid process be sufficiently advanced, it is abolished.

COLONIAL HEALTH REPORTS.

HONG-KONG.

THE civil population of this colony, says Mr. A. G. M. Fletcher, Colonial Secretary, in his report for 1922, was estimated at the middle of the year under review at 662,200, distributed as follows:—Non-Chinese civil community, 15,200. Chinese population: City of Victoria (including Peak), 340,000; villages of Hong-Kong, 25,700; Kowloon and New Koolon, 133,000; new territories, 84,000; population afloat, 64,300. Total Chinese population, 647,000. Total civil population, 662,200.

The birth-rate for the year was 6·25 per 1000 among the Chinese community and 22·84 per 1000 among the non-Chinese community, as compared with 5·68 and 25·88 for 1921; but it is stated in a footnote that "this figure is wholly misleading, as it is impossible to register more than a portion of the births." The death-rate for the year was 25·88 per 1000 among the Chinese community, and 20·46 among the non-Chinese civil community, as compared with 20·29 and 18·08 for 1921. The number of deaths from malaria were 454, from plague 1071, and from small-pox 189. There were 4863 deaths from respiratory diseases (other than pulmonary tuberculosis). Pulmonary tuberculosis claimed 1385 Chinese and 25 non-Chinese victims, whilst other forms of tuberculosis represent an additional 686 deaths, making a total of 2096, or 14·8 of the total deaths among the community. Beri-beri was responsible for 829 deaths, as compared with 526 during 1921. During the past few years circulars have been distributed to all large employers of coolie labour calling their attention to the fact that beri-beri is produced by the consumption of white rice as the staple article of diet without a sufficiency of other foods, and advising that beans should be supplied with the rice when fresh meat or fresh fish cannot be afforded.

Hospitals.—Government hospitals consist of the civil hospital (to which is attached an isolated maternity hospital), the Victoria Hospital for Women and Children, and the Kennedy Town Infectious Diseases Hospital. The civil hospital contains 170 beds in 21 wards; 4447 in-patients and 25,892 out-patients were treated during the year. The maternity hospital contains nine beds for Europeans, plus three extra beds, and eight for Asiatics. The Victoria Hospital at the Peak contains 41 beds, and during 1922 178 patients were under treatment there. At Kennedy Town Hospital, which contains 26 beds, ten cases were treated in 1922, all being infectious. The lunatic asylum is under the direction of the superintendent of the civil hospital. European and Chinese patients are separated, the European portion containing 14 beds in separate wards and the Chinese portion 16 beds; 235 patients of all races were treated during the year, and there was one death. The Tung-Wa Hospital, opened in 1872, is mainly supported by the voluntary subscriptions of Chinese, but receives an annual grant of $8000 from the Government. Only Chinese are treated in this institution. Chinese as well as European methods of treatment are employed in accordance with the wishes expressed by the patients or their friends. Over half the number are now treated by Western methods. The hospital is under the supervision of a visiting physician, who is a member of the medical department, whilst two Chinese house surgeons, trained in Western medicine, are members of the hospital staff. There are 450 beds in the buildings, and 8336 patients were accommodated during 1922. The Tung-Wa also maintains a branch hospital for small-pox cases (Chinese only). It contains 60 beds, and during the year 46 cases were treated. The Alice Memorial and affiliated hospitals are managed and controlled by the missionaries resident in Hong-Kong, agents of the London Missionary Society, and consist of the Alice Memorial Hospital opened in 1887, the Nethersole Hospital (1893), the Alice Memorial Maternity Hospital (1904), and the Ho Miu Ling Hospital (1906). The number of in-patients in 1922 was 1667. The number of labours in maternity hospital was 457. To avoid the complete seclusion from friends and relatives, which removal of Chinese plague patients to the Kennedy Town Infectious Diseases Hospital entailed, four district plague hospitals are now maintained by the Chinese in various parts of the colony. The Kwong Wa Hospital for Chinese in the Kowloon Peninsula was opened in 1911. The existing buildings contain 244 beds, and 5142 patients were accommodated during 1922. The Chinese public dispensaries are institutions maintained in order to provide the Chinese with the services of doctors whose certificates will be accepted by the registrar of deaths, and with the services of interpreters who can assist the inmates of houses where a case of infectious disease has occurred. Coolies are engaged and ambulances and dead vans provided in order to remove cases of infectious disease to the infectious diseases hospital and dead bodies to the mortuary. The dispensaries receive sick infants and send them to one or other of the convents and arrange for the burial of dead infants. Free advice and medicine are given and patients are attended at their houses. There are eight of these dispensaries in existence. The Government makes an annual grant of $7000 and the rest of the cost is defrayed by voluntary subscription.

The Medical School.—The University of Hong-Kong, ncorporated under the local University Ordinance, 1911, s a residential university for students of both sexes. It ncludes the three faculties of Medicine, Engineering, and Arts. The Faculty of Medicine provides a five-year course of study in the usual pre-medical and medical sciences, supplemented by clinical work in the Government Civil and Tung Wa hospitals leading to the degree of M.B., B.S. The degrees of M.D. and M.S. may be obtained for postgraduate work. The degrees above mentioned are recognised by the General Medical Council for registration in Great Britain. The site of the University was given gratuitously by the Colonial Government. In the main buildings are housed the chemical, physical, and biological laboratories. Special medical buildings include schools of anatomy, physiology, pathological and tropical medicine, erected at the cost of Chinese gentlemen resident in the colony. During 1922 a benefaction of $500,000 was received from the Rockefeller Foundation for the foundation of full-time chairs in medicine and surgery. The complete scheme ncludes a grant of a further sum of $250,000 for a full-time chair of obstetrics and gynæcology, and provides for the creation of complete medical units for the teaching of the three subjects in the Government Civil Hospital. The University is to make provision out of its own funds for assistants to the professors of anatomy, physiology, and pathology, and it is desired to erect a hostel for medical students in proximity to the hospital. Eight scholarships of $200 each were founded by the China Medical Board for medical students who shall have carried out their premedical studies at the Canton Christian College, the Univerity undertaking to remit fees to the extent of $100 a year.

ST. VINCENT.

The report for 1922, prepared by Mr. Robert Walter, C.M.G., administrator, states that the estimated population of the colony on Dec. 31st, 1923, was 46,744. The birthrate for the year was 41·99 per 1000 and the death-rate 22·21. Illegitimate births numbered 1455, or 74·1 per cent. of the total number of all births. The general health of he colony throughout the year was good. A mild type of nfluenza was prevalent. The colony escaped altogether he visitation of alastrim, which has caused so much distress n some of the neighbouring islands. Infantile diarrhœa was more prevalent than in 1922, and the number of deaths rom this cause, 138, shows an increase of 26 as compared with the previous year. The case mortality was 8 per cent., as against 13 per cent. in 1922. It is noteworthy that children's diarrhœa is worse during the rainy months, while he case mortality rate is greater during the dry months. The campaign against yaws by intramuscular injection of novarsenobillon continued to be pressed vigorously with very satisfactory results. During the year 3492 cases, ome 7 per cent. of the population, were treated, and of hese 79 per cent. were returned as cured. The following hospital accommodation is provided: Colonial Hospital, Kingstown, 86 beds (including 4 beds for private paying patients); District Casualty Hospital, Georgetown, 4 beds; and District Casualty Hospital, Chateaubelair, 4 beds. St. Vincent is one of the healthiest of all the West Indian slands. The climate may be divided into two seasons, wet and dry; the dry season from January to May, with an average rainfall of 4·04 inches per month, and the wet eason from June to December, with an average of 8·22 inches per month. The coolest months are December to April. The temperature throughout 1923 varied from 76·3° F. to 0·4° F.

TURKS AND CAICOS ISLANDS.

The area of these islands is estimated to be about 166 square miles, but as no thorough survey has ever been made this igure may be below the mark. The Turks Islands consist of two inhabited islands, Grand Turk and Salt Cay, four uninhabited islands or cays, and a large number of islets and rocks. These islands derived their name from a species of cactus found there by the early settlers, the scarlet head of which was said to resemble a Turkish fez. The Caicos slands, which lie to the west of the channel, surround the Caicos Bank, a triangular shoal 58 miles long on its northern ide and 56 miles long on its eastern and western sides espectively. The entire group, known as the Turks and Caicos Islands, extend for a distance of 75 miles from east o west and 50 miles from north to south, and constitutes part of the long chain of low islands and banks extending rom off the Florida coast to the Navidad Bank, lying north of the Dominican Republic. The Turks and Caicos Islands are generally considered to be healthy, but during the year 922 (according to the report of Mr. H. E. Phillips, the Commissioner), owing to various causes, the public health was not as good as usual. The infant mortality was higher than in former years, owing, no doubt, to the drought which necessitated the use of well-water for drinking purposes. The Government medical officer at Grand Turk reported that "this change of the drinking-water caused numerous cases of bowel trouble in both old and young," and expressed his opinion that "this was responsible for many of the deaths that occurred among the young children and infants." Alastrim, which had been imported from the Dominican Republic during the previous year, still continued to make its appearance during the first few months of 1922. Malaria, which is nearly always present, broke out in a severe form during the latter months of the year. Tuberculosis, which seemed to be on the decrease during previous years, increased to a notable extent during 1922, owing, in the opinion of the Government medical officer, to the lack of proper food during the drought and also to the lack of ventilation in the houses. The hospital accommodation provided consists of eight beds at the Manning Hospital at Grand Turk and four beds at the Cottage Hospital at Cockburn Harbour. As regards the Manning Hospital, during the year nine cases were admitted to the surgical ward for operation, and 16 to the medical ward for treatment. The tent which had been erected in the hospital grounds to receive alastrim cases during the previous year was kept in readiness during the first part of 1922 to receive any new cases which might be imported. The medical officer reported that the isolation of these cases of alastrim, and other precautionary measures, such as vaccination and the inspection of all ships arriving from abroad, were no doubt instrumental in preventing an epidemic of this loathsome disease from invading these islands. The estimated population of the Turks and Caicos Islands at the close of 1922 was only 5711. The white population, numbering about 200, is composed almost entirely of the descendants of Bermudians. During the year 211 births were registered, giving a birth-rate of 37·5 per 1000. During the same period 179 deaths were recorded, the death-rate being 32 per 1000. The readings taken at the Weather Bureau Station at Grand Turk, at a height of 11·3 feet above the sea-level, were as follows: Rainfall, 16·30 inches; maximum temperature, 87° F.; minimum, 60°.

NIGERIA.

The area of Nigeria, including the mandated area of the Cameroons, is approximately 367,928 square miles, and it is thus larger than any British dependency other than Tanganyika, India, and the self-governing dominions. It is more than three times the size of the United Kingdom. The population, according to the 1921 census, is 18,631,442. There are about 4000 Europeans temporarily resident, chiefly in the employ of the Government and of mercantile and mining companies. The country is not suitable for European settlement. Of the native inhabitants the greater number are of pure negro race, but in the north there are Berber and negroid tribes. In the more backward communities cannibalism still occurs, and is probably more common than is realised, and cases of slave dealing are still to be found amongst the tribes to the east of the Niger. In the report for 1923, prepared by Mr. H. O. S. Wright, senior assistant secretary, it is stated that the colony and protectorate have throughout the year enjoyed comparative freedom on the whole from epidemic diseases and from the attendant mortality that follows an epidemic through a country. The outbreak of cerebro-spinal meningitis that prevailed in the Kontagaro Province during 1922 recurred in the month of February, but the infection expended itself by March and April. The country has been particularly free from any severe outbreaks of small-pox, though during the first six months of the year a small recrudescence of the disease took place in its old haunts, comprising the Okigwi and Enugo districts. In the northern provinces it made its presence felt along the Benue River in the Mora and Yola provinces. In the Cameroons a moderate outbreak of the disease occurred in the districts of Buea, Mamfe, and Bamenda. It is of some interest to record that a few cases of relapse fever occurred in Lagos mainly during the month of September. "Health Week," initiated in Lagos in 1922, was held for the second time in December, 1923. Self-help being the principle, much of the organisation was left to the people themselves who had gained experience of its working previously. It is to be hoped that as the years go by and the people become better educated, more and more will interest themselves in assisting to promote the health of the community. A visit to the Iqu waterworks was a real success, for over 1000 persons availed themselves of the opportunity of seeing how the town water was purified.

The seasons in Nigeria depend rather on the rainfall than on temperature. They are, as a rule, well defined. The dry season, with its attendant "Harmattan," commences in the north of the country in October and ends in April. It is of shorter duration in the south, and at Lagos generally lasts from November to March with only intermittent

"Harmattan." This is a dry north-easterly wind which brings with it a thick haze composed of minute particles of dust and shell. During its prevalence the nights and early mornings are cold, but the days are very hot, and it is during this period that the maximum diurnal variations occur. Generally speaking, the lowest mean temperature is in the months of July and August, and the lowest minimum recorded temperature at the beginning and end of the year. The highest mean and maximum temperatures are, as a rule, recorded in March and April. At the end of the dry season numerous tornadoes herald the approach of the rainy season which lasts until October, with a slight break in August. In the south the prevailing wind during this season is from the south-west, and with it comes the rain, which is remarkably heavy along the coast and decreases rapidly as it travels inland. The average annual rainfall at Bonny on the coast is 163 inches (in 1921 245 inches were registered). At Lokoja, situated at the confluence of the Niger and Benue, it is 48 inches; and at Sokoto, in the north-west of Nigeria, it is only 25 inches. The average rainfall at Lagos is 72 inches. In the northern parts of Nigeria there is literally no rain whatever for the greater part of the dry season: for 12 years no rain has fallen at Sokoto during the four months November to February.

LEEWARD ISLANDS.

These islands form the most northerly group of the "Lesser Antilles" in the West Indies, and lie between 18° 27′ and 15° 10′. The colony is now a federation, comprising the five presidencies—formerly separate colonies—of Antigua; St. Christopher (usually called St. Kitts), with which presidency is included Nevis; Dominica; Montserrat; and the Virgin Islands. The report for the year 1922–23, recently issued, states that the total population of the colony, according to the census of 1921, was 122,242, showing a decrease of 4951 when compared with the census for 1911. The birth- and death-rates are given as follows:—

	Population.	Birth-rate per 1000	Death-rate per 1000.
Antigua	29,512	37·24	33·51
St. Kitts	21,650	39·8	33·8
Nevis	11,854	37·5	20·4
Anguilla	4,362	33·2	18·3
Dominica	38,108	39·83	31·11
Montserrat	11,957	34·5	21·9

The general health of the colony during the year was satisfactory, and although epidemics of alastrim existed in Dominica from July, 1922, to August, 1923, the disease was of a comparatively mild type, only six deaths occurring. Thorough vaccination took place throughout the colony, and it is considered improbable that a similar invasion will occur for a long time to come. There is a central lunatic asylum at Skerrets, Antigua, and there are two leper asylums, one at Rat Island, Antigua, and the other at Fort Charles, St. Kitts. The mean rainfall in Dominica was: at 14 Leeward stations, 76·31 inches; at 3 Windward stations, 115·49 inches; at 4 inland stations, 211·51 inches; and at 5 Lasoye stations, 97·24 inches. In Antigua the average rainfall, taken at 70 stations for 49 years, is 44·18 inches, and the rainfall for 1922 was 35·14 inches, or 9·04 inches below the average. In St. Kitts the rainfall at La Guerite station was, for the year 1922, 39·7 inches.

ST. HELENA.

His Excellency Colonel Robert Francis Peel, C.M.G., the Governor, in a report on this colony for 1923, estimates the population at 3654. Births during the year numbered 114 (not including two still-born) and deaths 28, giving a birth-rate of 31·19 per 1000 and death-rate of 7·66 per 1000. The general health of the community continued to be satisfactory. A mild but widespread epidemic of influenza prevailed in the months of January and February, repeating the experience of the previous year. During these two months the trade wind frequently fails, and this occurrence certainly favours the spread of air-borne infection. There were 157 admissions to hospital during the year and 7 deaths occurred, equal to a death-rate of 4·5 per cent. New and convenient quarters were provided for the nursing staff at St. John's Villa, which has been taken over by the Colonial Government from the Admiralty, and which, after complete renovation, was occupied by the nurses in April. The mean temperature for the year was 62·0° F., the absolute maximum being 80·1° on July 25th, and the absolute minimum 50° on July 8th. The total rainfall recorded at Hutt's Gate was 45·74 inches, at Plantation 45 inches, and in Jamestown 10·14 inches.

QUEEN ALEXANDRA.

To the Editor of THE LANCET.

SIR,—On Dec. 1st Queen Alexandra attained her eightieth birthday (having been born at Copenhagen on Dec. 1st, 1844). She was married to King Edward VII. (then, of course, Prince of Wales) on March 10th, 1863, and in THE LANCET of March 14th of that year you had a leading article commenting upon the happy event, in which you stated that "the universal blessings which hallowed our welcome of a fair young stranger to her future home implied more than the exuberant greeting of an enthusiastic people. Past happiness and future hope found therein a simultaneous expression," and also "we do from this marriage anticipate special results." Sixty-one years have elapsed, and many special results from that marriage have been realised, as will be admitted on all hands with grateful recollection, not the least being the King Edward's Hospital Fund and the Alexandra Fund, established in 1912, with its exceedingly popular Rose Day, by which over a million pounds have been raised. Those who have seen the various books on the lives of King Edward and Queen Alexandra will have a good idea of their beneficent activities.

I am, Sir, yours faithfully,

Nov. 27th, 1924. W.

*** In regard to the Alexandra Fund, Miss C. May Beeman, C.B.E., the organiser, informs us that in 1925 the Rose Day will be held on the second and not the third Wednesday in June, that is, on the 10th, in order not to clash with Ascot.—ED. L.

OBSTINATE CONSTIPATION.

To the Editor of THE LANCET.

SIR,—In regard to the request by "Clinical" in THE LANCET of Oct. 11th for suggestions as to treatment for a young patient suffering from chronic and unrelieved constipation, if this condition is induced by hypo-thyroidism (a likely cause), I suggest a course of thyroid gland treatment, ½ gr. doses, which may be combined with 1 gr. pituitary whole gland, t.d.s., a.c. Should there be any duodenal insufficiency, eukinase, in granular form, after meals, is also indicated. Frequent and excessive purgatives should be avoided. The recurrent rise of temperature is possibly caused by intestinal intoxication, due to colonic stasis, and is often a grave complication. Suitable diet and abdominal massage, &c., will assist the patient.

I am, Sir, yours faithfully,

Trinidad, Nov. 11th, 1924. R. C. BENNETT, M.B.

To the Editor of THE LANCET.

SIR,—In answer to the request made in "Clinical's" letter published in the last issue of THE LANCET to hand (Oct. 11th) I would suggest that he try treatment with bile, ox or pig, by mouth and by enema. Very little stress is laid on the use of bile in the university courses on therapeutics, but recent experience has convinced me that no other treatment is so efficient in cases of obstinate constipation such as "Clinical" describes. I could cite several instances quite as bad, if not worse, that have been completely cured by this simple mode of treatment. Perhaps the reason why bile is so seldom used is because it is such an unpleasant thing to take by mouth, besides being liable to go bad, but pills of pig and ox bile are made in quite a convenient form by Burroughs, Wellcome and Co., and both pills and a preparation for use as an enema are made by the Laboratoire Panbiline, Annonay, Ardêche, France.

I am, Sir, yours faithfully,

South Africa, Nov. 6th, 1924. C. LUNDIE.

TEACHING ON CONTRACEPTION.

To the Editor of THE LANCET.

SIR,—In view of your contention, in an annotation published last week entitled Teaching on Contraception in Medical Schools, that students' text-books on gynæcology omit to discuss the principles and technique of contraception, you may note that in "Gynæcology and Obstetrics," by Dr. J. S. Fairbairn, reviewed in your own columns on its appearance some six months ago, a section in the chapter on Social and Ethical Aspects is devoted to an exposition of this subject. I am, Sir, yours faithfully,

A STUDENT.

*** Dr. Fairbairn's remarks on the subject are clear and impartial.—ED. L.

A WARNING.

THE Chief Constable of Leeds sends word that a man who gave the name of Mr. Ferguson, aged about 70, called on a doctor in that city and asked for financial assistance. He stated that he was a doctor, and obtained his M.B., Ch.B. Edin. in 1894, and had practised in Harley-street and Henrietta-street, and also in Edinburgh, and at present he was residing at Bradford. He produced a letter purporting to be written by another doctor, who had apparently assisted him to the extent of 10s. No one with the name and qualifications given appears on the Medical Register.

An Address
ON
NVALIDITY FROM CHRONIC JOINT DISEASE.

Delivered before the Royal Institute of Public Health

BY JAMES R. KERR, C.B.E., CH.M. GLASG.,
SURGEON IN CHARGE OF THE PILKINGTON SPECIAL HOSPITAL, ST. HELENS, LANCS.

IN the report on the Incidence of Rheumatic iseases, issued by the Ministry of Health, there re arresting figures showing the amount and the ost of industrial invalidity from diseases, acute and hronic, classed as "rheumatic." We find that hronic joint diseases cost the approved societies early £1,000,000 a year in sick benefit, and are esponsible for the loss of over 1½ million weeks of ork per year. From the financial standpoint alone he importance of chronic joint diseases is therefore ery great.

The chronic joint diseases to which I shall refer clude chiefly the conditions variously described as eumatoid arthritis, osteo-arthritis, and arthritis eformans, other forms of arthritis being excluded. he thesis I submit consists of two parts—(1) that he term "rheumatic" when applied to chronic int diseases is frequently misleading, and is a ource of danger to the patient; (2) that intensive rthopædic treatment can do much to counter the isabilities associated with these diseases.

DIVERGENT VIEWS OF THE PATHOLOGY OF RHEUMATIC DISEASES.

Now, although these chronic joint diseases are enerally classified as "rheumatic," there is hardly ver a complete and convincing discernment of the teps and stages from their chronic condition back o the well-defined specific fever known as acute heumatism. Yet, as Prof. R. Stockman, of Glasgow, oints out, "rheumatoid arthritis" is not an inap- ropriate term since, as in acute rheumatism, so lso here, we have (*a*) lesions of the fibrous tissue of he locomotor system, and (*b*) the joints prominently volved. The confusion of nomenclature is very reat, and we find eminent authorities at diametric ariance one with the other, the reason being the nsatisfactory state of the ætiology and pathology f the disease. Indeed, on any accepted classification here are, say, 15 per cent. of cases which do not it into any of the categories.

For the present purpose I cannot deal with the acteriological researches of the past, nor can I ven refer to the present lines of investigation. We o know, however, that many varieties of micro- rganisms are capable of producing arthritis in man nd in rabbits. We also know that during an attack f acute rheumatism a certain amount of immunity ust be established, seeing that natural cure takes lace. As Prof. Stockman says:—

> "The reason of the rapid and complete disappearance of nflammation from the joints is of extreme interest. It can nly be explained by supposing the development of a local mmunity through the formation of an antibody, but such mmunity is evidently not very lasting, as the same joint may gain become inflamed during the illness. So far as I am ware no researches have ever been made to elucidate this. t is possible that the closed cavity of a joint favours the ufficient accumulation of an antibody, for the same rapid ubsidence of inflammation does not take place in the open ibrous tissue structures, but rather the contrary. In them he inflammation tends to linger on."

We may take it, then, that our pathological know- edge of acute rheumatism has got some length, eeing that we acknowledge the existence of causal rganisms, the formation of antibodies, natural cure, nd therefore some degree or type of immunity. Further, it is well known that in a joint suffering from acute rheumatism the synovial membrane is in a state of intense hyperæmia, the cells on its surface proliferating and containing many nuclei. These are the changes one finds in any infection of a joint, and they are similar to the reactive efforts of any acutely inflamed region.

Many chronic joint disabilities called "rheumatic" run a less clearly observable course. We know that the liability to attacks of acute rheumatic fever diminishes after the age of 35 years, and that the bulk of the chronic joint lesions are recorded in patients over that age. Yet 80 per cent. of these chronic joint patients give *no* history of a previous attack of acute rheumatism, and so one can infer that acute rheumatism does not predispose to joint disability of the chronic type at a subsequent date, and it is even conceivable that a degree of immunity is established against what we may reckon as a low-grade infection, whose results take months or years to become manifest.

There is considerable evidence, clinical and pathological, tending to suggest that the causal agent produces its various effects, subject to the modifying conditions of its immediate environment and of the physiological or pathological state of the joints and synovial membranes of the host, and that throughout the range of chronic "rheumatic" disabilities definite co-relation exists. I would class these disabilities under one category, although the prominent manifestations in differing types demand treatment apparently different, yet fundamentally and essentially based on definite visualisation of the pathological changes, the present stage, and the likely course of the disease in each case. The most appropriate name can be determined later, but it is of interest to note that the Encyclopædia Britannica (Medical) in 1901 stated that the terms arthritis deformans, rheumatoid arthritis, and osteo-arthritis are synonymous and indistinguishable; that the American view is that arthritis deformans is a synonym for rheumatoid arthritis and quite distinct from osteo-arthritis; and that authorities in both countries are found to accept or reject these classifications. It would be clearly wrong to dogmatise, but I am bound to say that in the important matter of the amelioration or cure of the patient's disability the pathological pictures I have formed have proved most useful as foundations on which to base prognosis and treatment.

COURSE AND ORDER OF THE JOINT CHANGES.

Briefly, I assume that cartilage and bone changes in the joint follow after failure of the synovial membrane and antibodies within the joint. The stage of even extensive hypertrophic villous synovitis may endure for years before cartilage erosion at the weight-bearing surfaces takes place, but wherever the hypertrophied synovial membrane is constantly in contact with cartilage some erosion is liable to occur. In operating on such knee-joints one observes the hyperæmia and loss of lustre of the cartilage at the region of the subpatellar pad, at the margins of the condylar notch which is non-weight-bearing, and also at the periphery where villous masses lie constantly overlapping. Accordingly recession of the hypertrophic synovial membrane is one aim of our treatment associated, of course, with orthopædic considerations regarding joint function. One is aware that much research has been directed towards the discovery of the causal organism of this chronic villous synovitis, and we find that a disease has been called "chronic villous arthritis" on account, no doubt, of the cartilage erosion observed. To explain the observation of the two appearances within the joint—namely, the villous hypertrophy and the cartilage erosion—it has been suggested that probably several different organisms are producing the long-continued irritation. I urge that the avascular cartilage is affected secondarily, and that chronic villous arthritis is the later stage of chronic villous synovitis—i.e., when cartilage erosion has occurred—and, in fact, that those chronic joint diseases actually consist of different stages or combinations of stages of the one disease.

Theories and views may require modification as further facts are disclosed. It may be that recurrent attacks of subacute or mild rheumatism in a joint have the effect of devascularising, sclerosing, and atrophying the synovial membrane and rendering it less liable to respond—10, 20, or 30 years later—to the continuous or intermittent stimulus of organism or toxin.

The Synovial Membrane.

It seems to me that the end-result in a joint varies with the type, previous history, and present condition of its synovial membrane. I believe that synovial membrane has a highly specialised function, of great adaptability, comparable to the omentum or the peritoneum, which also are called upon to deal with a variety of assaults. As an example of the adaptive and defensive powers of the synovial membrane one may cite the case of sepsis in the knee-joint. The modern surgical treatment of sepsis in the knee-joint is based on an enlightened appreciation of the power and function of the synovial membrane, and has given results which are in contrast to those of the former methods, and recovery of function has been obtained in hundreds of cases. Yet when we consider a joint having a different type of synovial membrane, as, e.g., an inter-phalangeal joint, we find that a correspondingly unsatisfactory response is made by it, and the most modern treatment of infection in such a joint gives results which are often very bad. The synovial membrane seems to me to be the important factor in the resistance of a joint to invasion—microbic or toxic, chronic or acute. The pathological changes resulting seem to have close relation to the functioning power of the synovial membrane of the particular joint concerned. It must be borne in mind that synovial membrane is not really an epithelial structure. It consists of flattened, irregular, stellate, connective-tissue cells, with definite gaps in the surface, so that the term epithelioid is more accurate. It has between it and the fibrous tissue capsule a layer of soft fatty tissue which pushes and expands the synovial membrane down into any vacancy in the joint as the normal movements are executed. There are loops of blood-vessels in intimate relation with the peri-articular vessel groups, and on stimulus the vessels of synovial membrane become engorged, and a reactive, defensive hyperæmia is produced. Proliferation of the epithelioid cells occurs, and eventually synovial fringes may be formed, as is observed in numerous cases. The knee-joint responds readily to treatment, and this, I think, is due to the reactive possibilities of its synovial membrane. After the synovial membrane has become fibrous, sclerosed, and devascularised, then one expects and finds that the cartilage becomes thinned, and degeneration and atrophy proceed. Later fibrous tissue from the bone, and ultimately bone itself occupies the joint spaces.

Degenerative Process in Different Joints.

In the case of the knee-joint there is a long and successful resistance to this degenerative process, but in the hip-joint its advance is steady. Yet in these cases of "morbus coxæ senilis," or "chronic osteo-arthritis" of the hip, which are not uncommon in patients between 30 and 40 years, it may be that in the absence of a completely adequate protective and adaptable synovial membrane, some degree of protection is still offered. At all events, in cases where X ray examination shows a relatively early stage of the disease we find that appropriate orthopædic and physiotherapeutic measures give some relief to the general condition, and also seem to effect some retardation in the progress of the disease. In the presence of advanced bony changes one has, of course, to use some of the modern plans to relieve pain and secure stability and power of locomotion.

In the finger-joints reactive hypertrophy of synovial membrane is limited by the firm and tight capsule and periarticular structures, and one finds degenerative changes relatively early, although it has to be remembered that these are secondary to contracture and are chiefly of the decalcification type, which is amenable to treatment.

THE PRACTICAL ASPECT.

The foregoing will probably serve to indicate the enormous field open to research in this subject. With regard to what may be called the practical aspect my experience of cases previously investigated elsewhere, who had suffered removal of various infected organs and had undergone medical and massage treatment, but who nevertheless were crippled with joint lesions, makes it manifest that while research was seeking the actual ætiology a great deal remained undone to relieve what one may call the symptoms—which really are of first concern to the patient. It seemed to me clear that the first warning of joint injury—microbic or toxic—was given through the synovial membrane. In particular, knee-joints gave early signs, although many patients delay seeking help till the signs are advanced and serious crippling threatens or is actually present.

A Typical Case.

Let me sketch a typical case—a married woman of 48 who has been bedfast for six months owing to contractural flexion of both knees, which were swollen and painful when moved. The label rheumatism had been applied. The friends and neighbours sympathised. The eldest daughter was recalled home from a good post, and as she had been the chief wage-earner for the household there was financial catastrophe, especially for its younger members. All this was because of the patient's inability to walk about the house and attend to even directional domestic duties. What the woman suffered from was chronic villous hypertrophy of the synovial membrane of her knee-joints, and modern treatment has proved successful beyond expectations. I need not detail the procedures we employ, but it is sufficient here to say that everything is guided by orthopædic considerations and with a view to the functional needs. The knees are straightened without delay, all harmful reaction in the joint being avoided. Rest and repair are encouraged by supporting appliances modified to suit, and from time to time as progress is made. Intensive physiotherapy directed to the atrophied muscle groups, and particularly towards increasing the blood-supply collateral with that of the pathological synovial membrane, such agencies as hot water, hot air, melting paraffin wax, ionisation, faradic stimulation, massage, mechano-therapy, &c., being used for the purpose, the forms of treatment and the dosages being selected appropriately. In three weeks the patient should be able to stand up, and in two weeks more to walk with two sticks, although her hips will still be stiff from flexion-deformity developed while she was bed-fast. Progress then goes on rapidly, and she is restored to some degree of working capacity in, say, three months. In her case X ray examination reveals no bony change, and in all probability bone changes will develop very late in the disease, if at all, provided that the posture and function of the joints are maintained by the proper means.

A joint untreated degenerates and disintegrates, with erosion of cartilage, and fusion of bone following the usual course, and accompanied by hip, ankle, and foot deformities, which render even the nursing services most difficult and discouraging in the comfortless downward path which inevitably awaits the patient. Briefly told, that is the story of thousands of women. The balance seems to be delicately poised between power of resistance and the gradual assailability of synovial membrane as regards these chronic infections. Appropriate treatment commenced at a reasonably early stage turns the balance in the ajority of cases. The necessity for wage-earning, or he demand of domestic duties prevails in a great umber of cases to delay the moment of seeking elp, and so one finds these patients working on for ears with steadily increasing disabilities, relieved om time to time by periods of rest, till a stage of otal disability arrives, when general and local onditions are unfavourable for rapid or complete ecovery. About 1 in every 100 working women etween the ages of 45 and 55 years suffers from ome chronic joint trouble, most commonly in the nee, and both knees are often affected. The number f cases among men is almost as great. Chronic joint iseases cost the approved societies about £1,000,000 er year (as has been stated already), but there has to e reckoned also the personal loss of wages and the uffering. This enormous bill can be reduced by early nd adequate treatment on the lines I have outlined. t has to be remembered that many women between 5 and 55 years of age are employed in domestic rvice, mostly outdoor, and being dependent on heir earnings they tend to suffer long till crippling isables them and the duration of their incapacity ecomes very great. Sooner or later they become a harge on the country.

In the most broad way I have depicted one type f case, its course and its treatment, and the results.

PRINCIPLES OF TREATMENT.

In many respects the patient in better financial ircumstances is often not much more fortunate. er general condition is well looked after, but the ocal or orthopædic needs may have insufficient ttention, and time, from this point of view, seems be lost in visiting various resorts according to the eason, and to overlooking several primary warnings. rrors can be made by attempting to relieve "rheuaticky" knees without reviewing the entire locootor apparatus. Systematic examination usually eveals a predisposing cause of some prolonged rain. It may only be an increasing eversion and ronation of the feet associated with some degree of nock-knee, but to stabilise the limb by rectifying a abitually bad posture with possibly the help of odifications in the footwear may make all the ifference in the activities of a woman. Foot strains nd foot pains from any cause require correction. he patient's general fitness may have been well aintained, but the "creaky" and stiff knees do ot respond satisfactorily to the general treatment hich has been undergone, and usually require pecific and specialised attention. The rate of proress of the crippling is, of course, slow, but, on the ther hand, it has to be noted that after a good egree of recovery has been obtained by treatment, he joints can be kept in satisfactory condition by an ccasional short course of treatment.

A similar chronic condition of synovial hyperrophy is common among men also, and in view of he frequency of an injury being the attributable ause, a careful preliminary examination of the knee required. When a blow is stated to have been eceived the situation is nearly always described as st below the knee-cap. In cases of a twist or wrench he same region is indicated. On examination one ommonly finds a thickened and tender subpatellar ad. The question of aggravation by injury or ccident arises, but we need not discuss it here.

The Operation of Synovectomy.

Under treatment improvement or recovery follows. great deal of industrial invalidity in men arises om this condition of the knee-joint. In certain ases the recurrent effusions, associated with the reat hypertrophy of the synovial membrane, have amaged the knee ligaments, and instability is becomg an additional complaint, wage-earning power eing absolutely lost. In selected cases I have perrmed the operation of synovectomy, excising in ne mass the entire suprapatellar pouch with its xcessively hypertrophied and its grossly villous synovial membrane. The posterior compartment of the joint, and any fringes or villi at the periphery or elsewhere, are cleared out as much as is possible. This operation is performed through the split-patella route and a painless, weight-bearing, and movable joint is obtained in most cases. Even with a limited movement in the joint the stability and freedom from pain are highly acceptable to the patients. In the case of a working man free knee movement is an important additional consideration. We plan the post-operative treatment for early active and passive movements—i.e., commencing about the tenth day, and continue towards full range of movement with contemporaneous development of muscular power by faradic stimulation, massage, and exercises. The procedure is utilised at the Mayo Clinic, and the success of their earlier cases is now encouraging them to operate in less advanced conditions, and this seems a logical course, for at the operation one can eradicate at least 90 per cent. of the disease in the joint. We thus see that invalidity from this very common form of chronic disease in the knee-joint can be enormously reduced by the methods described. For most cases intensive physiotherapy treatment with correction of simple orthopædic errors is sufficient. In the ultimate or penultimate stages, carefully planned and possibly extensive operative intervention may be required.

Similar methods are applicable to other joints, which, however, do not usually offer so good a prognosis as in the case of the knee. In children and young adults the rapid course which the disease sometimes takes in the direction of cartilage erosion and its sequelæ requires a most guarded prognosis. Each case and condition requires a full review and careful diagnosis. Postural and static and most painful disabilities of the feet, often called "rheumatics," which the sufferers, especially women, accept quite patiently as a heritage, do not come under our scope except from the point of view of error in diagnosis and their relative susceptibility to alleviation by proper means. Nor need one refer further to the so-called "rheumatic" pains in knees, hips, and spine due to sudden alterations in the height of the heel of the shoe, either to meet a changing fashion or to maintain deportment as weight and age increase. In so many cases are "bunions" quasi-traumatic and postural results, that the association with chronic joint diseases need not occupy us here.

In the upper limb disease of the shoulder follows the course of the hip, but the weight-bearing factor is absent. Here periarticular lesions, unless treated, are followed steadily by postural cripplings, which later require vigorous and thorough correction.

In the elbow-joint we find that chronic disease is accompanied at an early stage by bone changes, which are visible under X ray examination. Here the differential diagnosis from myositis ossificans requires to be borne in mind, particularly as the patient may be only, say, 30 years of age, and the question of occupational injury may arise. The wrist and hand are particularly affected by what is described as rheumatoid arthritis or infective periarthritis, the latter term being accurately descriptive. Women are great sufferers from this type, being affected according to various age-groups, from two to six times as frequently as men. The inter-phalangeal joints of one or both hands are first involved. They first appear swollen and spindle-shaped, but pain is not prominent. The general appearance of the patient suggests a toxic state, and, as one would expect, further joints are progressively involved, particularly those of the carpus. X ray examination shows no bony change at first. The swelling is due to thickening of the synovial membrane, the capsule, but chiefly of the periarticular fibrous tissues. Later, when X ray examination shows great modification of the joint structures, these consist of the signs of atrophy and disuse. Later, again, there is dislocation from contractures, fibrous ankylosis, and ultimately bony union. The early bone changes are those of decalcification, which are essentially trophic changes, and are similar to those found frequently after nerve lesions.

Physiotherapy for Degenerative Changes.

Experience of intensive physiotherapy treatment of such degenerative changes goes to show that in many cases they are definitely amenable to great improvement, so that subsequent X ray examination shows restoration of the joint contours and joint spaces, and that is a point I want to urge, not only because of the financial loss to the worker and the State, but also because of the patient's suffering and distress of mind which follow the incidence of this disease, and the attitude of helplessness which has tended to encompass all connected with its course. Here, as in the chronic knee condition, the synovial membrane remains till the penultimate phase in a state of reactive hypertrophy, but in these smaller joints, of a different structure, offering less room for expansion, and probably defective in blood-supply, for example, the joint of the phalanges or of the carpus, the accompanying accommodative hypertrophy and proliferation of the synovial membrane cannot take place to a sufficient extent. But if one gets cases before new fibrous tissue predominates in the joint cavity, much can be done by physiotherapy treatment. In later stages other methods are employed according to the needs of the case, and the ingenuity and orthopædic skill available. The treatment of these conditions is an uphill fight at all times, and not being associated with dramatic effects, such as are achieved in acute abdominal work, it demands of those in charge of the case temperamental qualities of a kind recognised well by the unfortunate victims.

My remarks have aimed chiefly at establishing a working basis on which treatment should proceed. A large experience under particularly favourable conditions convinces me that it is well worth while urging for early recognition and treatment of these chronic joint diseases which are contributing to so much suffering, invalidity, and loss of money to the industrial population.

On the ætiology and pathology of chronic joint disease earnest and able investigators are at work. Much has been achieved, but the last words are still to be written. Here, as in virtually all instances of scientific advance, practice breaks ground for theory, and it is not beyond the record to say that hope is being radiated on the afflicted from the results of intensive, coördinated, persistent treatment, carried on with confidence and in the modern orthopædic spirit.

CHRONIC BACKACHE IN GYNÆCOLOGY.*

By DANIEL DOUGAL, *M.C.*, M.D. MANCH.,
ASSISTANT LECTURER IN OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF MANCHESTER; GYNÆCOLOGICAL SURGEON, MANCHESTER NORTHERN HOSPITAL.

A GOOD deal has been written in recent years about chronic backache in women, and on the whole the tendency has been to take a broader view of the subject. Formerly, a woman with backache was considered to be the peculiar property of the gynæcologist, but the pendulum has now swung in the other direction and large numbers of these cases are claimed by the general physician and the orthopædic surgeon. Martyn,[1] writing from the physician's point of view, believes that many of the backaches are due to infection and obtains good results by attention to septic foci in the mouth and throat. Goldthwait[2] thinks that undue mobility of the sacro-iliac joints as a result of pregnancy or even menstruation is an enormously frequent cause of the backache, and would therefore consider most cases to be orthopædic in origin. When full allowance has been made for these cases there will still remain a large number in which a definite gynæcological lesion is present, and the importance of this lesion is shown by the good results which follow its removal by surgical treatment, For instance, Bullard[3] claims 85 per cent. of cures in 721 cases of backache treated in this way.

It is generally agreed that women suffer more frequently from backache than men, and their greater susceptibility must therefore be due to physiological or occupational factors peculiar to the sex. Certain forms of housework no doubt put a special strain upon the spinal muscles, but these occupations are not more tiring than the heavy work of unskilled labourers for instance, and so far as I know the latter do not suffer in any special way from pain in this region. The occupational factor must therefore be relegated to a position of secondary importance, and the real cause sought for in some lesion directly or indirectly connected with the sexual organs. The function of menstruation, the growth of the uterus, and the stretching of neighbouring structures in pregnancy, the strain on the abdominal muscles, pelvic joints, and supports of the uterus and pelvic organs during labour, and the special liability of the female sexual organs to infections and tumour formation, readily explain the greater incidence of backache amongst women.

Backache is a very common symptom in gynæcological patients, but varies much in severity and may be so slight as to be of little importance. In some women it is obviously severe, in others it is only mentioned in reply to a leading question, so it is difficult to obtain reliable information as to its frequency One hundred and twenty-nine hospital patients were asked specifically if they were troubled with backache and 43 per cent. answered in the affirmative. This figure no doubt includes many of the slighter cases and rather exaggerates the importance of the symptom A better plan is to take a series of cases where the clinical history has been investigated by one individua in a uniform way and each patient allowed to describe her symptoms without any prompting. There are obvious disadvantages in this method, but on the whole the results will give a fairer idea of the rea importance of backache. I have studied the case cards of 1000 patients seen in my own consulting-room and the results form the basis of the following observations. In the series I found that 235 cases, or about 23 per cent., complained of backache, and that it was the principal symptom in a third of this number

Gynæcological backache is generally confined to the lower lumbar and sacral regions, especially the latter, and is not usually the only or indeed the chief symptom. Its value in diagnosis is therefore small, and for this reason it is apt to receive very little attention. The pain is often looked upon a part of a neurosis—"some women's backs always ache"—but although this may be true of some cases there remain a large number where a definite lesion can be discovered and the pain cured or very much relieved by suitable gynæcological treatment. The backache varies much in character; it may be described as a dragging or twisting, as a dull constant ache, or as a soreness. It is generally located ove the sacrum, sometimes to one or other side, and i often associated with pain in the lower abdomen and less frequently with pain down the thighs. One patient wrote: "I am not free from pain in the lower region of my back about six square inches." The pain may be constantly present or only fel after exertion or at definite times in relation to the menstrual periods. It may be of long standing dating from before marriage or even from puberty but in the majority of married women the trouble i stated to have commenced shortly after a confinement

Social and Obstetric History.

The great majority of the cases investigated belonged to the class who either have to earn thei own living or perform heavy household duties at home Twenty-two of the patients were single, rather les than 10 per cent.

---

* Being one of the opening papers of a discussion before the Manchester Medical Society on Dec. 3rd.

The figures as to pregnancy were as follows :—

Married, nulliparæ	48 (21 per cent.)
,, uniparæ	54 (23 ,, ,,)
,, multiparæ	102 (45 ,, ,,)

Gynæcological Lesions Associated with Backache.

The diseases found to be most commonly associated ith backache were genital prolapse, chronic cervicitis, ndometritis and metritis, adnexal and peri-uterine nflammation, uterine fibroids, adenomyoma, and ancer of the cervix. Table I. gives the total cases each group, and the number and percentage of ose complaining of backache.

TABLE I.

Disease.	Total cases.	Cases of backache.	Per-centage.
enital prolapse	227	66	29
hronic cervicitis	44	26	59
hronic endometritis ..	108	46	42
hronic metritis	53	11	20
dnexal and peri-uterine inflammation	101	25	24
terine fibroids	82	15	18
denomyoma, &c.	29	15	51
ancer of cervix	35	9	25
varian tumours	31	3	9

There were 63 cases with no gynæcological lesions, nd 10 of these complained of backache. It is not ontended, however, that of over 200 cases of backache nly 10 were non-gynæcological; the results of perative treatment show that even when the gynæcogical lesion is cured, some of the patients still omplain of this symptom, and in many of these he pain was probably due to an entirely different ause. Retroversions and retroflexions of the uterus ave not been placed in a separate group although hey are generally looked upon as the principal auses of backache. They do play a part, but not a redominant one, and in my opinion the size of the terus, the condition of its walls, and the strength r otherwise of the supporting structures of the pelvic oor are of more importance in this respect than ere changes in the direction of the uterine axis. obile retroversions and flexions have been included the cases of prolapse, chronic endometritis, and hronic metritis, and the adherent cases naturally ll into the group of adnexal and peri-uterine inflamations.

The term chronic endometritis is open to criticism n pathological grounds, and is used here merely as matter of convenience to describe the type of case fully investigated by Donald and Fletcher Shaw.[4] he symptoms as described by these authors are enorrhagia, metrorrhagia, leucorrhœa, dysmenorhœa, and chronic pain, and two or more of these are enerally present in each case. The physical signs re enlargement of the uterus with undue tenderness n bimanual examination. Table II. shows the osition of the uterus and the incidence of backache 108 cases belonging to this group.

TABLE II.

Chronic endometritis.	Total cases.	Backache present.	Per-centage.
nteversion and anteflexion .	78	31	40
etroversion and retroflexion	30	15	50

The figures show that, although backache is ndoubtedly more common with retroversion and etroflexion, the greater frequency is not sufficient o warrant the importance attached to these dislacements in this connexion.

Results of Operative Treatment.

All the backache cases were "followed up" and sked about the effect of the operation on this articular symptom. Replies were received from 152 patients as follows: No backache since operation, 69; much improved, 42; no better, 41. The improved cases generally stated that the backache was now only felt after any special exertion. The replies taken as a whole show that 73 per cent. of backaches associated with a gynæcological abnormality were cured or much relieved by appropriate surgical treatment, and that in 45 per cent. the pain completely disappeared after the operation.

Results of Treatment.

The results of treatment in the different groups must now be examined.

Genital Prolapse.—The operation performed in every case was a double colporrhaphy with or without amputation of the cervix. Replies (51): No backache since operation, 30; much improved, 12; no better, 9. The results in cases of prolapse are therefore distinctly good, the backache being cured or much relieved in 80 per cent. of cases. The figures include seven cases of complete prolapse and all were completely cured by colporrhaphy.

Chronic Cervicitis.—Two cases were treated by total hysterectomy (and not relieved of their backache), the others by curetting and amputation of the cervix. Replies (20): No backache since operation, 7; much improved, 6; no better, 7. The results in this group are moderately good, 65 per cent. being cured or much relieved.

Chronic Endometritis.—The majority were treated by curetting, the results from this operation being as shown in Table III.

TABLE III.

Uterus.	Cured or much relieved.	No better.	Total.
Anteversion and anteflexion ..	10	3	13
Retroversion and retroflexion ..	4	3	7

In addition to the above, the uterus was replaced by a round ligament sling operation in four cases, but the results were very disappointing. One patient was rather better till she became pregnant again when the pain recurred, the other three reported that the backache was as bad as ever. The figures are much too small to throw any light on a subject about which there is such a wide difference of opinion, and it is only fair to state that very high claims have been advanced by those who make a practice of replacing the uterus by operation in cases of backward displacement. Bullard found that backache was complained of in 129 of 149 cases of mobile retroversion and succeeded in curing about 80 per cent. by replacement operations. Donald and Fletcher Shaw lay no special stress on backache in chronic endometritis even when the uterus is retroverted, but include it under the heading of chronic pain. In 107 cases treated by curetting this symptom was improved in a little over 84 per cent., and the general result of the operation was rather better in cases where the uterus was retroverted. As to the good results claimed by ventrifixation and similar procedures, these authors believe that if some degree of prolapse is associated with the other changes in the uterus the sensation of weight and dragging may be relieved by these operations. It is very easy to overlook a certain degree of prolapse especially when the patient does not actually complain of anything coming down, and I think that in many of the cases of retroversion with backache the pain is chiefly due to weakening of the pelvic floor. My figures in the prolapse group prove that backache can be cured or much relieved by colporrhaphy in a large percentage of cases, although the uterus still remains in a backward position after the operation.

Chronic Metritis.—Replies (8): No backache since operation, 4; much improved, 1; no better, 3. The uterus was anteverted in eight and retroverted in three of the 11 cases of chronic metritis. One case was treated (and cured) by curetting and radium, the others by total or subtotal hysterectomy. A third of the patients were not relieved of their backache even after removal of the uterus and appendages.

Adnexal and Peri-uterine Inflammation.—Replies (21): No backache since operation, 9; much improved, 7; no better, 5. 76 per cent. were cured or much relieved by operation, and the results were better in cases where both appendages were removed as well as the uterus.

Uterine Fibroids.—Replies (13): No backache since operation, 7; much improved, 4; no better, 2. In only four of the 13 cases was the tumour sufficiently large to cause pressure on the pelvic walls and the backache was presumably due to the weight of the enlarged uterus.

Hysterectomy, either total or subtotal, was performed in every case and the ovaries were also removed in all except two (both cured).

The results are quite good, but the percentage of complete cures is not as high as one would expect. A heavy and enlarged fibroid uterus is such an easily understood cause of backache that its removal would be thought to give complete relief in almost every case.

Adenomyoma, &c.—In this group are included the adenomyomata involving the tissue behind the cervix and also the cases of "tarry" cysts or "endometriomata" of the ovaries. Replies (10): No backache since operation, 3; much improved, 3; no better, 4. The results as regards backache are not very good considering that the uterus and appendages were removed in every case, but this is not surprising when it is remembered how the growth infiltrates the rectal wall and pelvic cellular tissue. One of the worst cases of chronic backache I have seen belonged to this group. At the first operation double ovarian "tarry" cysts were removed but not the uterus. The pain in the back became more severe, and as much nodular thickening could be felt behind the cervix it was decided to try the effect of a total hysterectomy. This was done, but the adenomyomatous tissue could not be completely removed as it surrounded the rectum and extended on to the lateral pelvic wall. The patient recovered well from the operation, but her backache remains as bad as ever.

Cancer of the Cervix.—Nine cases of cancer of the cervix complained of backache and of these all but two were inoperable. Wertheim's operation was performed in the operable cases and both are well at the present moment and quite free from backache.

The Mechanism of Gynæcological Backache.

I am convinced that the great majority of gynæcological backaches are due to certain muscles becoming fatigued as a result of extra strain being thrown upon them. The spinal muscles may be affected in this way in the case of large abdominal tumours, but with lesions confined to the pelvis the strain falls chiefly on the muscular components of the pelvic floor, the levatores ani. These muscles are normally protected against undue strain by the strong fibromuscular tissue of the parametrium, but when that barrier is weakened by stretching or by the weight of a large uterus or tumour they may become fatigued and cause aching pain in the back. This appears to be a reasonable explanation of those cases of backache associated with enlargement of the uterus or prolapse. There may be more than one factor present in a particular case, and this may account for the fact that the backache still persists after removal of the more obvious cause. For instance, of the cases treated by removal of the uterus and appendages, 30 per cent. still complained of this symptom after operation. Fatigue occurs more readily in some individuals than in others, depending on the condition of the nervous system, and we therefore find that the backache is not a constant symptom in these conditions and may even be improved by attention to the general health and without removing the actual cause.

In cases where there is no question of pelvic floor weakness the pain may be due to irritation of the sensory nerves which serve the pelvic viscera and are contained in the sympathetic system. These fibres are the axons of spinal ganglion cells, and so the pain may be referred to the somatic area supplied by these same ganglia—i.e., the back and lower abdomen. The source of irritation may be some abnormality of the sexual organs themselves (inflammatory conditions of the uterus, especially the cervix, &c.), or a lesion affecting the pelvic cellular tissue and involving the sympathetic nerves and plexuses there (advanced cancer of the cervix, adenomyoma, pelvic cellulitis, &c.).

Conclusions.

1. Chronic backache is an important symptom amongst gynæcological patients, being present in from 20 to 30 per cent. of all cases.
2. The importance of backache in uncomplicated retroversion and retroflexion has been much exaggerated as it is found almost as frequently in cases where the uterus is in a forward position.
3. The most important factor in producing backache is fatigue of the pelvic-floor muscles, and this may result from increased weight of the uterus but more frequently from stretching of the parametric tissues.
4. Where there is a definite indication for surgical treatment the backache can be cured or much relieved in over 70 per cent. of cases, the results being especially good in cases of prolapse treated by colporrhaphy.

MASSIVE COLLAPSE OF THE LUNG IN ACUTE POLIOMYELITIS.

Case Reports and Comments.

By JOSEPH C. REGAN, M.D.,
ASSOCIATE, DEPARTMENT OF PEDIATRICS, LONG ISLAND MEDICAL COLLEGE.

(From the Kingston Avenue Hospital of the Bureau of Hospitals, Department of Health, New York City.)

The occurrence of massive collapse of the lung in acute poliomyelitis is a condition of such rarity as to warrant the report of a case. A search of the literature of Heine Medin's disease has been entirely without result so far as the finding of a similar example is concerned. It is doubtful if the rarity of atelectasis in acute poliomyelitis is as great as this would seem to indicate. Other instances may have been overlooked in the study of the more prominent clinical phenomena, or may have been considered as pneumonic complications. This is the more likely, as the condition would presumably originate mostly in the bulbo-spinal forms of the disease in which the medulla and upper cervical region of the cord are involved, and such cases are many times rapidly fatal. The following report of a patient presenting this unusual symptom of a massive collapse of the lung was observed at the Kingston Avenue Hospital.

S. M., girl, aged 10 months, was admitted on Nov. 10th, 1921, with a diagnosis of acute poliomyelitis.

History.—Family history irrelevant. Previous history: varicella at 4 months.

Present Illness.—On Nov. 9th the child developed a high fever (104° F.) and the physician called made a diagnosis of pneumonia. Towards evening the parents observed that the child was breathing very rapidly, and that there was retraction of her lower chest with respiration. The child was in a drowsy state and "slept all day." On the 12th it was noticed that the neck was weak, so that the child could not hold her head up; the fever, however, had entirely subsided. On the following day the temperature remained normal, and for the first time a suspicion of poliomyelitis was entertained by the family physician.

Physical Examination on Admission.—The child is a well-nourished and very well-developed baby, mentally quite bright, but at present extremely irritable on being disturbed, and quite acutely and desperately ill. She lies in her crib with her head turned to the right, crying continually in a peculiar low, soft, feeble voice. The skin and lips are of a rather cyanotic colour. Her respirations are extremely embarrassed. The respiratory rhythm is irregular and of exaggerated jerky type, characterised in inspiration by a marked upward and forward movement of the chest with the accessory muscles brought into play, and a visible tugging movement of the larynx and trachea, associated with a retraction of the upper abdomen, giving it a scaphoid appearance. On expiration there is an equally sudden downward movement of the ribs and a protrusion of the abdomen. When the child cries the respirations become more rapid, and assume a still more irregular rhythm, and beads of perspiration stand out on the face. The pulse is very irregular. The second sound at the apex is of a slightly impaired quality. MacEwen's sign is present and markedly positive. The neck is painful on manipulation and when the child is lifted up the head drops backward. The pupils are equal and react to light. The expression of the face is very anxious, the skin is of an ashen-grey colour with cyanosis of the lips, and dilatation of the alæ nasi occurs with inspiration. There is an asymmetry between the two sides of the face, noticeable when the patient cries.

Lungs.—The left side especially shows pronounced physical signs which might at first be taken for those of a pneumonic consolidation or effusion. There is impairment of resonance over the left lower posterior chest, including the axilla from the seventh rib downward, and over this same area there are markedly diminished breath sounds or rather almost inaudible breath sounds. Above this area is broncho-vesicular breathing approaching in a few places a pure bronchial note; no râles of any kind heard. On the right side posteriorly there are dullness and slight diminution of breath sounds over the lower few interspaces.

Abdomen.—Liver and spleen are not palpable.

Extremities.—The left upper extremity is partially paralysed, the child apparently being unable to lift the arm above the head. The lower extremities and right upper extremity are apparently normal, except for the loss of the patellar reflexes and slight polyneuritis in the former. No Kernig, Oppenheim, or ankle clonus. The back and neck muscles are weak and the child is unable to sit up. The temperature, pulse, and respiration ratio on admission was 99°, 128, and 62. At no time was the temperature subsequently elevated above normal, and the respirations reached 32 by the fourth day in the hospital.

Subsequent Clinical Course.—Nov. 16th: The peculiar type of breathing still persists but the rate is normal when the child is not disturbed. The paralysis of the face has almost entirely disappeared. The child's general appearance is greatly improved since admission. She still perspires when she cries, and at such times the chest excursion increases greatly and she becomes slightly cyanotic. The cardiac arrhythmia persists, although it is not so pronounced. Her neck muscles and right upper extremity are still paralysed, and the muscular power in the right leg is less than in the left. 20th: General condition is improved. There has been a change in the lung signs. The percussion note over the left lower chest has now altered to an impaired resonance and the breath sounds are more audible at the base than previously, but there is still a marked diminution in vesicular breathing. The right side, on the contrary, presents more pronounced signs. There is impairment of resonance over the entire right lower posterior chest with dullness above. On auscultation there is intensified respiration somewhat broncho-vesicular in type over the right interscapular region, and absence of vesicular breathing over the lower four or five interspaces. No râles and no temperature. 26th: Lungs: The right side anteriorly shows slight impairment of resonance and diminished aeration, especially of the right axillary region. Posteriorly. there is dullness throughout most all of the right posterior chest with an almost flat note over the lower few interspaces, and on auscultation broncho-vesicular breathing over the right upper chest, diminished breath sounds over the upper portion of the right lower, with absence of breath sounds at the base. The left side posteriorly shows an almost normal percussion note and only a diminution in respiratory murmur over the lower three interspaces. Neck and back muscles weak, right lower and left upper extremities unchanged. Dec. 8th: Symptoms unchanged with the exception of the lung findings. The signs anteriorly over the right side are same, but posteriorly there is now normal percussion and breathing as far as the seventh rib, downwards. From there one finds dullness and absence of breath sounds. The left side is practically normal. 13th: The child's general condition and symptoms have improved. With support she can stand and even walk. Jan. 5th: Child convalescent. Breathing is now normal. The left lung shows normal physical signs; the right lung presents a very slight diminution in resonance and in breath sounds at the right base. There is slight dropping of the right shoulder apparently from atrophy of the muscles around the shoulder-joint and she cannot raise her arm above a right angle with her body. The heart rhythm is regular. Dec. 15th, 1922: She walks well, and the gait is steady, but there is slight limping with the right leg, which is considerably under the left in development. The chest is well developed, with normal respiration. No atelectatic areas found. Lumbar punctures were made on nine occasions, from 10–26 c.cm. of clear fluid being withdrawn under pressure, marked at first and afterwards moderate.

Laboratory Data.—(1) Spinal fluids:—Nov. 15th: Globulin, –; Fehling's, 3 plus; 30 small lymphocytes per c.mm. 21st: Globulin, 1 plus; Fehling's, 3 plus; 20 small lymphocytes per c.mm. Colloidal gold curve: 1–1–2–2–1½–½–0–0–0–0. Dec. 15th: Globulin, –; Fehling's, 3 plus; 7 small lymphocytes per c.mm. Colloidal gold: 1–1–1–1½–0–0–0–0–0–0. (2) Cultures from nose and throat: Negative for K.-L. bacilli; Schick test negative. (3) Urinary analysis: Negative for albumin and sugar. (4) Blood count: Total leucocytes, 11,200; polymorphs, 50 per cent.; small lymphocytes, 44 per cent.; large lymphocytes, 5 per cent.; transitionals, 1 per cent.

Discussion.

The diagnosis of acute poliomyelitis and atelectasis is scarcely open to question. A pneumonia and pleurisy with effusion would certainly not have presented the symptoms and signs which accompanied the pulmonary process. The rarity of massive collapse of the lung in acute poliomyelitis lends importance to the case, but a greater interest still attaches to the manner of its production. It is not necessary here to cite in detail the various subdivisions of the two main types of acquired atelectasis—namely, the obstructive and the compression forms—to show that the ætiological factor could not have been any of the well-recognised causes. There are only two possible explanations: (1) the compression of the base of the lungs by the paretic diaphragm, which, although passively, nevertheless carried on an increased respiratory excursion accompanying the dyspnœic type of breathing (which was so peculiar to the case); and (2) the obstruction of the bronchi by inhibition or paralysis of the broncho-dilator fibres of the vagus with over-activity of the broncho-constrictor fibres or tonic activity from irritation of the broncho-constrictor fibres; in either case leading to a constriction of the bronchial muscles and a collapse of the portion of the lung innervated. Between the two possibilities it is not an easy matter to decide, and, indeed, we are in a similar position in this regard to that in which Pasteur [1] and Bradford [2] found themselves in attempting to explain in the former author's cases post-operative massive collapse and in the latter's the same condition occurring after gunshot wounds, especially of the chest. Both were strongly inclined to believe that the condition of relative immobility and retraction of the chest wall and diaphragm on the affected side, which was present, was primary and the collapse secondary. The chest wall in this patient was not immobile, neither was the diaphragm. Hence, we cannot attribute it to this cause. Even if they were, it is certainly open to question whether diaphragmatic weakness or paralysis alone is a frequent cause of atelectasis, for if so we should certainly have expected it long ago to have found a place under the symptomatology of that condition. This case is more suggestive, of course, in the sense that the diaphragm, although in an inversion of its normal rhythm, had a very forcible although passive movement, which might possibly have compressed the bases of the lungs.

The second possible explanation demands serious thought. As far back as 1842 Longet concluded that the vagus nerve supplied constrictor fibres to the bronchial muscles, and subsequently many classical experiments have been carried on which appeared to prove that the lung may be made to contract on vagal stimulation. Mention may be made of the work of Roy and Graham Brown[3] in this regard. Later Dixon and Brody[4] concluded that the vagus contained both broncho-constrictor and broncho-dilator fibres which they believed were controlled by a double medullary centre. They showed that collapse of the lung on the one hand or over-distension on the other might be produced, depending on the force of inflation in one instance and the time allowed for deflation in the other, as a result of bronchial constriction following vagal stimulation in experimental animals. Within the past few years Vernet[5] has called attention to the work of Lesbre and Maignon, who showed that excitation of the eleventh cranial nerve caused the contraction of the muscular layers of the bronchi, and had advanced this as an additional support of his view that the pneumogastric is the sensory nerve and the spinal accessory the motor nerve to the lungs.

Both Pasteur and Bradford admit the possibility of some obscure reflex phenomena in their cases of atelectasis as a cause of the immobilised chest wall and collapsed lung. Pasteur went further and stated that the post-operative cases he had collected had commonly occurred after laparotomies on the lower abdomen, and that the initial disturbance had been either within or in close proximity to the area of distribution of some branches of the vagus nerve. Neither Pasteur nor Bradford was able to present any facts which would clearly indicate that the pulmonary collapse was purely secondary to the immobilisation of the chest wall or the weakness or paralysis of the diaphragm.

Our patient, it will be remembered, presented symptoms which were decidedly suggestive of a cardio-respiratory syndrome of bulbar origin. Peabody, Draper, and Dochez,[6] in their classical monograph on poliomyelitis, have observed a very similar cardiac arrhythmia in several of their fatal cases and applied the name of a rhythmic arrhythmia to it, believing it also to be a vagus nerve disturbance. Wickman[7] has mentioned likewise the peculiar bulbar crisis with attendant changes in pulse and respiration seen at times in Heine Medin's disease. One is therefore thoroughly justified in considering a bulbar lesion in our patient, and if there is a broncho-constrictor and broncho-dilator centre in the same area it is perfectly logical to infer that they might have been concerned in the acute congestive lesion induced by the poliomyelitic virus in the immediate region of these nerve centres. From such a standpoint this case is important as it gives better grounds than previously cited instances for the belief that a true paralytic atelectasis may exist. Further research is required to throw light on this problem, and to show whether paralytic atelectasis may exist, and to study the peculiar reflexes arising which may account for some of the phenomena seen in such cases as those reported by Pasteur and Bradford.

Summary.

A case of acute poliomyelitis is reported in which there occurred a massive collapse of the lower lobes of the lungs, involving first predominantly one side and later the other. Atelectasis in poliomyelitis is a complication of considerable rarity, and could not have been produced by any of the commonly recognised causes of the condition. Two possible explanations are to be considered: (1) The compression of the bases of the lungs by the paretic but over-active diaphragm which kept pace with the dyspnœic respiration which was so peculiar to the case; and (2) the paralysis of the broncho-dilator fibres or the over-activity of the broncho-constrictor fibres of the vago-spinal nerves, in either case leading to constrictor action and a collapse of the dependent lung. While the former explanation cannot be excluded as the primary cause the latter may be more logically incriminated in our case, owing to the concomitant existence of a cardio-respiratory syndrome of bulbar origin. The possibility of a paralytic atelectasis should be given more serious thought in the future both from the experimental and clinical standpoints, so that if it really occurs, as our case is suggestive in indicating, its existence may be established on a more definite basis.

CONJUGAL TUBERCULOSIS.

BY STEPHEN ROWLAND, M.D. EDIN.,
D.P.H. CAMB.,
TUBERCULOSIS OFFICER, NORTHAMPTON.

THE subject of conjugal tuberculosis has received much attention from medical writers, who, however, display a great lack of unanimity as to the frequency of its occurrence, the manner of infection, and the morbidity of the disease in the two partners.

Divergent Opinions.

The generally accepted opinion has been that conjugal infection seldom occurs, but recently Dr. E. Ward, tuberculosis officer for South Devon, has published results which seem to show it is by no means uncommon. If we accept the inhalation method of infection as the only one which takes place in phthisis, one would expect, considering the intimate relations of a married couple (where they are, for more than 8 hours out of the 24, under ideal conditions for infecting each other) transmission of the disease from one partner to the other would be relatively a common occurrence. It would appear to a casual observer that it must be merely a matter of time before one partner infects the other, where one is an open case of phthisis—i.e., is excreting tubercle bacilli in the sputum, as practically all phthisis cases do before the end. Any case in which T.B. cannot be found in spite of marked physical signs in the chest should be looked upon with suspicion, and the diagnosis reconsidered. The writer is convinced that many cases of what Dr. Clive Riviere[1] so aptly labels "damaged lung" have been in the past, and still are, looked upon and treated as phthisis. Nevertheless, in spite of ideal conditions for the transmission of infection, it very seldom occurs, and Fishberg,[2] after a careful study of the subject, goes so far as to say it never takes place. He examined 9 women and 161 men. Out of this number there was only 3 per cent. of cases where husband and wife were tuberculous. On the other hand, Sir Hermann Weber[3] found in 68 persons, male and female, who, with more or less pronounced consumptive taint, had married healthy partners, that ten of the partners of these 68 cases became consumptive, or 14·7 per cent. Dr. Ward[4] in THE LANCET gives the results of his examination of husbands and wives of tuberculous patients, and out of a total of 156 examined (120 wives and 36 husbands) he found 91 to be tuberculous, the astonishing figure of 58 per cent. The above differences are rather difficult to explain.

As far as the writer can ascertain the greater part of the work on conjugal tuberculosis has been carried out with regard to "infection" rather than with regard to "death" of the partner. It is his opinion this is not the most satisfactory method of attacking the problem, as it leaves too much to the personal equation of the observer. What one clinician may consider a case of early infection may be rejected by another as not showing sufficient symptoms or physical signs to warrant a diagnosis of pulmonary tuberculosis. In the writer's opinion the most accurate information regarding the amount of phthisis amongst both married and single is to be obtained from death certificates, for in the closing phases of the disease the chance of error in diagnosis is reduced to a minimum, and for this inquiry death certificates alone have been used. The writer has investigated the 1242 deaths from phthisis which occurred in the borough of Northampton during the ten-year period 1911–20, with a view to ascertaining the frequency of conjugal tuberculosis, as compared with the findings of other observers—i.e., the frequency of death from phthisis of the spouse of a tuberculous person.

Historical Outline.

Dr. Tillische,[5] of the Grefsen Sanatorium, Norway, published in 1914 the result of his inquiries into the previous history of 841 patients, with a view to ascertaining in what per cent. of them clinical tuberculosis had existed in childhood. He found evidence of it in 156 cases, or 18·5 per cent. This figure agrees with the figure Dr. Harbitz arrived at during his work as a pathologist. Dr. Sophie Tillische[6] gave in *Tubercle* the result of her own investigations during the ten-year period 1911–20, the period embraced by the writer's examination into the deaths which occurred in the borough of Northampton certified as being due to pulmonary tuberculosis. Amongst the 3151 sanatorium patients examined by Dr. Tillische 1152 were married, and of these 85, or 7·4 per cent., were found whose consorts were also tuberculous. Thirteen of these 85 cases are excluded as being too doubtful to include amongst those of undoubted conjugal origin. There remained 72 cases, or 6·2 per cent. of the total, in which "tuberculosis can in all probability be assumed to have been conveyed from one partner to the other." Even in this group there are isolated cases not above suspicion—i.e., with a history of tuberculosis in the inner family circle. If these figures be accepted it shows that marriage with a consumptive does carry with it a certain amount of risk for the healthy partner, that risk being, roughly speaking, doubled. Amongst the 1152 married persons there were 94 widows and widowers. In 44 of these cases, or in 47 per cent., the consorts of these patients had died from tuberculosis.

These observations deal entirely with sanatorium patients, and no mention is made as to the presence or absence of T.B. in the sputum. Much stress cannot be laid on the information gleaned as to the presence of tuberculosis in both parents, which is usually very unreliable, and to be of any statistical value requires to be supported by written evidence.

Arnold Minning,[7] of Denver, U.S.A., investigated 1000 successive dispensary cases, of whom 502 were married, classifying none as tuberculous which were in the least doubtful. His conclusions are as follows: 1. He finds the incidence of marital tuberculosis to be 8·76 per cent., and when a consort dies the mate has been infected in 50 per cent. of cases. 2. There is such a thing as adult infection, and we should constantly bear this in mind in our advice to the layman. 3. It is evident that when there is a continued massive infection over a period of years, and especially when the consort dies (in these last years patients are especially careless and slovenly), there is not only a possibility of contagion, but in one out of every two cases active tuberculosis supervenes. 4. These investigations covered only dispensary cases. In private practice the incidence of marital infection is smaller, proving that intelligent prophylaxis is worth while.

Dr. Harry Lee Barnes,[8] of Wallum Lake, Rhode Island, gives in the *American Review of Tuberculosis* his experiences of 2262 married persons admitted to the Rhode Island State Sanatorium between Nov. 1st, 1905, and May 5th, 1921. Of these 62, or 2·7 per cent., claimed to have partners suffering from pulmonary tuberculosis. Barnes rightly states that statistics based on patients who have had consorts die from tuberculosis are more valuable, not only because plenty of time may elapse for the development of the disease, but also because death is something definite. Patients' statements that their consorts died from consumption, like the physicians' certificates on which they are usually based, are subject to occasional error, yet they probably minimise rather than exaggerate the number of cases of tuberculosis. Barnes draws two conclusions from his investigations: 1. The histories of 229 consecutive widowed patients admitted show that 40 per cent. lost their consorts from tuberculosis, a tuberculosis mortality over three times as great as that of the married people of the community. 2. Immunity from many diseases is short lived, and until much more convincing evidence of permanent immunity against tuberculosis conferred by infection during childhood is forthcoming, a cautious logic will not accept the confident statements that are being made as to the impossibility or rarity of adult infection.

Burney Yeo[9] collected records of 1055 cases of consumption which came under his notice in hospital. Of this number 621 were males and 434 were females. Of the males, 306 were married, 297 were single, and 18 were widowers. Of the 18 widowers only two, or about 11 per cent., could state positively they had lost their wives by consumption. Of the 434 females, 199 were married, 206 were single, and 29 were widows. Only five, or 17 per cent., were able to state positively that their husbands died from tuberculosis. In the writer's opinion these figures, whilst interesting, are not very reliable from a statistical point of view, representing only the statements of patients, and taking no account of other sources of infection or tuberculosis in the inner family circle.

Among 159 couples in which one of the partners was tuberculous, Brehmer[10] found that in 19 cases, or 12 per cent., both suffered from the same disease. Brehmer was dealing with "infection," not with "death," and much depends upon what evidence he based his findings. Haupt,[11] on investigating 417 cases, found 22 instances, or 5·2 per cent., in which both partners were affected by tuberculosis. Here, again, it is a question of "infection," not of "death." Cornet[12] found amongst 594 couples both partners were tuberculous in 23 per cent. of the instances. The same criticism may be offered as in Haupt's cases. Jacob and Pannwitz[13] collected information from a number of German sanatoriums, and found conjugal tuberculosis present in 8·57 per cent. of the cases. Weinberg[14] found amongst 1426 husbands of tuberculous wives that 118, or 8·3 per cent., died from tuberculosis, and amongst 2506 wives of tuberculous husbands 112, or 4·5 per cent., succumbed to the disease, or amongst 3932 consorts of tuberculous persons 230, or 5·9 per cent., died from tuberculosis. He finds the mortality from phthisis amongst those married to consumptives is about double that observed in the general population. It will be noted that Weinberg's observations embrace a large number of cases, and deal with death, not merely with infection. Ludwig Levi[15] investigated 317 married couples who lived in poverty and want; 34 shared the same bed. This group is one in which marital infection might be expected to reach its maximum, but he only found $2\frac{3}{8}$ of the disease was due to marital infection. Another study was made by Crouch,[16] of the Modern Woodmen Sanatorium, Colorado Springs, U.S.A., embracing 2771 married men and 233 widowers. Out of these 193, or 6·4 per cent., had wives who either showed a history of tuberculosis or who died from it. When he took the widowers he found that 136, or 58 per cent., lost their wives from tuberculosis. He concludes that 58 per cent. of tuberculosis amongst 233 widowers is more than a coincidence. The writer agrees that such a figure, if a correct one, points to more than a coincidence, but he would like to see the patients' statements supported by death certificates before accepting them.

More Recent Studies.

Dr. Paul Roussel,[17] assistant physician to the Sanatorium des Pins and the Villemin Dispensary at Nancy, has recently published a memoir on the subject. At the dispensary he found both husband and wife were tuberculous in 11·6 per cent. of 423 families investigated, and 25 per cent. of tubercle amongst the children of these families. These figures led him to conclude that in 11·6 per cent. of open pulmonary tuberculosis marital infection had occurred, and 37·5 per cent. of the children were affected. If *all* cases were included, the percentage of conjugal infection dropped to 5·2 per cent., and the infection rate for the children to 25 per cent. Dr. Roussel also makes the interesting observation that, as a rule, conjugal infection is milder than other infections, especially those of children, the difference being explained by a sur-infection in one case and a primo-infection in the other. An infection frequently repeated at short intervals seems to be the most dangerous. The danger of repeated infections at short intervals is what one would expect. The dose is repeated before the protective mechanism is properly established—i.e., during the negative phase, when for a time immunity is actually lowered.

One of the most recent and interesting communications on the frequency of conjugal tuberculosis was published by Dr. E. Ward[18] in The Lancet. After examining a large number of contacts Dr. Ward finds himself in marked disagreement with the generally accepted view that conjugal infection rarely if ever occurs, and his figures are of such a nature as to rule out the theory of assortive mating, or mere coincidence. He believes the important factor in the spread of tuberculosis is direct infection, not predisposition. In other words, it is the sowing of the seed, not its falling upon suitable ground which leads to fresh cases of the disease—i.e., to its spread. His figures are shown in tabular form.

Table showing the Result of Dr. Ward's Observations on Conjugal Tuberculosis.

—	Number exam.	Tub.	Suspect.	Negative.	Percentages.		
					Tub.	Suspect.	Negative.
Husbands: Wives first notified ..	120	66	12	42	55	10	35
Wives: Husbands first notified ..	36	25	4	7	69	11	20
Totals	156	91	16	49	58	10	32

It is Dr. Ward's opinion that the majority of the spouses of tuberculous husbands and wives sooner or later show signs or symptoms of tuberculosis. He makes a further interesting and far-reaching statement in which he says that not only do they develop consumption, but the great majority recover and make a speedier recovery than do tuberculous patients whose disease is not due to conjugal origin. This, he thinks, may be owing to an acquired immunity due to repeated infections by graduated doses of bacilli. He thinks the subject of conjugal or marital infection should be reconsidered in the light of recent findings, as upon a correct view of the subject, involving as it does the whole question of childhood or adult infection, depends the success of the present and future campaigns against tuberculosis.

Arent De Besche[19] and Jorgen Jorgensen have recently investigated this subject, using the statistical material of the City Board of Health of Kristiania. They found that in 11 cases (1·48 per cent.) it may be assumed that life in wedlock with a person suffering from infectious tuberculosis had been the prime factor in the development of their own tuberculosis. The authors conclude that a slight tuberculous infection during childhood very probably offers a considerable protection against tuberculosis in later life, the immunity thus acquired being, however, only relative, so that exogen infection during adult life will always be of some importance in the ætiology of tuberculosis. There is some risk connected with life in wedlock with an individual suffering from open infectious pulmonary tuberculosis.

The late Ernest G. Pope,[20] of the Adirondack Cottage Sanatorium, Saranac Lake, N.Y., was at the time of his death engaged on the problem of conjugal tuberculosis. The work has been completed and edited by Dr. Karl Pearson. As a result of investigation by modern statistical methods Pope arrived at the following conclusions: 1. It is possible that there is some sensible but slight infection between married couples. 2. That this is largely obscured or forestalled by infection from outside sources. 3. That liability to the infection depends upon the presence of the necessary diathesis. 4. That assortive mating probably accounts for at least two-thirds and infective action for not more than one-third of the whole correlation observed in these cases.

Ætiology and Pathogenesis.

When one considers the apparent facility for infection of the sound partner where the other is suffering from open phthisis the most remarkable feature of the problem is the number who escape, or at least do not die from the disease. It may be taken for granted that phthisis is infectious, and whether a mixed infection plays a large or small part in bringing about the fatal end, there is no doubt that the tubercle bacillus is the causative organism, and it is by repeated doses of this organism that the disease is produced. It is familiar to all that cough is generally a prominent feature of the disease, and it is chiefly by means of the cough that the source of infection is spread around the patient; the more violent the cough, the more widely is the infection scattered by the droplets of saliva and sputum thrown in the air with the paroxysm of coughing, especially as so few patients take the precaution of shielding the mouth with a handkerchief, &c. When we remember that the sound partner passes a large part of the day and often the whole night in close proximity to the sick one, it is difficult to see how he or she escapes.

The writer is convinced the risk of infection is slight even in those cases in which practically no precautions are taken to guard against it. The explanation is that by the time men and women have reached the marriageable age they have passed the age of greatest susceptibility, which the writer believes is during childhood. In no other way can he account for the few deaths of the partners of tuberculous persons where so many factors which would lower resistance and favour the onset are present, especially amongst the working class—e.g., anxiety, want of rest, and frequently want of food.

While some workers, Roussel and Ward, believe the most important factor in the production of marital infection is the sowing of the seed, Pope finds that two-thirds of the infection is due to the seed falling upon a suitable soil—i.e., to the tuberculous diathesis. That there is such a predisposition or diathesis is apparent from the number of persons of the same families included in the 1242 deaths investigated by the writer, viz.:—

	Instances.	
Brothers	33	Three families each lost three brothers.
Sisters	22	Four families each lost three sisters.
Father and son ..	13	Including one father and two sons.
Father and daughter ..	14	Includes three instances of father and two daughters and father, son, and three daughters.
Mother and son ..	7	In one instance, mother, son, his wife and child.
Mother and daughter ..	8	
Brother and sister ..	30	

The Northampton Figures.

When we come to consider the figures for the Borough of Northampton we find that 1242 deaths from phthisis were certified by medical practitioners during the ten-year period 1911–20, and when we examine the marital state of these 1242 persons we find them divided as follows: Married, 525; single, 562; widowed, 49; state unknown, 106. Amongst this number we only find 15 instances where both partners have been certified as having died from phthisis within the decennium under consideration, and from these 15 it is necessary to reject one couple owing to a history of tuberculosis in the inner family circle, rendering the source of infection too doubtful to be included amongst the cases of genuine marital infection. Out of the 1242 deaths from phthisis in Northampton in ten years, we can only find 14 couples of whom it may be said that one partner probably infected the other. As the number of deaths of married persons was 525, the 14 accepted cases give a figure of 2·7 per cent. There are several other instances where married couples have died from phthisis; but one of the spouses has died outside the ten-year period under consideration. If by extending the period under review these had been included, we would, of course, have obtained a larger number, but the total deaths from phthisis would also have been greater, and I see no reason for believing the percentage figure for married couples would have been increased.

Others who have made a study of marital tuberculosis with the percentages of contagiousness they have found in their investigations are given herewith. Elasser, 39 per cent.; Gebser, 5 per cent.; Joussert, 3 per cent.; Thom, 3 per cent.; Arent De Besche and Jorgen Jorgensen, 1·48 per cent.; Turban, 6 per cent.; Ludwig Levy, 2·8 per cent.; Ward, 58 per cent. It will be noticed there is a marked difference in the findings of these investigators, ranging from less than 1·5 per cent. to the astonishing figure of 58 per cent., but it must be remembered some of these workers dealt only with infection, a very doubtful quantity varying with the personal equation of the observer, whilst the figures for Northampton deal solely with deaths where errors of diagnosis are surely reduced to a minimum. Now, the figure 2·7 per cent. for the amount of contagiousness amongst the married couples in Northampton varies little from the generally accepted figure for the clinical tuberculosis rate for the general population.

Amongst the 14 accepted cases the husband was notified first in eight instances, and in the remaining six the wife was notified before the husband. The average period between notification of the husband and wife when the husband was notified first was approximately 25 months, but when the wife was notified before the husband it was 32 months.

Summary and Conclusions.

My investigations lead me to the following conclusions:—

1. Conjugal tuberculosis is rare.
2. The death-rate from phthisis of the spouses of tuberculous persons varies little from that for the general population of a corresponding age. The phthisis death-rate for Northampton 1911–20 was 1·4. For England and Wales during the same period it was 1·1.
3. Ideal conditions for infection exist, but infection rarely occurs owing to the age of greatest susceptibility having passed by the time the marriage age is reached.
4. My findings support the view that infection usually occurs during childhood, hence the advisability of protecting children whose parents are suffering from open phthisis. Upon these lines the Grancher system is founded, and is being worked successfully in France.
5. When conjugal infection does occur the disease usually runs a relatively short course.

THE PREVENTION OF STILL-BIRTH.

By GILBERT I. STRACHAN, M.D. Glasg.,
M.R.C.P. Lond., F.R.C.S. Eng. & Edin.,
ASSISTANT GYNÆCOLOGIST TO THE CARDIFF ROYAL INFIRMARY; FIRST ASSISTANT TO THE PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE.

In papers dealing with obstetrical difficulties it is usual for the claims of the mother to be considered almost to the exclusion of those of the fœtus. While it is agreed that, in cases of danger to life, there should be no hesitation in sacrificing the fœtus in the interests of the mother, it appeared to the writer that it would not be out of place to consider the means most suitable for saving the life of the fœtus in cases where it might be in danger.

Causes of Still-birth.

Before considering the means of preventing still-birth, it is advisable to glance, for a moment, at its causes. Prenatal fœtal death is brought about usually by some condition which interferes with the placental circulation. The most common of these conditions are syphilis, toxæmia of pregnancy, nephritis, eclampsia, and retro-placental hæmorrhage. In such cases, if the dead fœtus is not expelled at once, it will be more or less macerated when born, and the placenta will probably show hæmorrhages or infarctions or, in syphilitic cases, will be large and pale. Intra-natal death occurs during the course of labour and is usually due to fœtal injury. The strain causing the injury falls mainly on the cranium, and the effect is, by compression of the head antero-posteriorly, to cause such vertical elongation that the tentorium is pulled on and is torn near its attachment to the falx, with hæmorrhage (Eardley Holland). In other cases intra-cerebral hæmorrhage occurs, sometimes, and especially in premature fœtuses, into the ventricles. Hæmorrhages, in some cases accompanied by rupture, are occasionally seen in the liver and suprarenals—less commonly in the other organs; rarely these hæmorrhages may be brought about by forcible pressure, more often they are due to vascular back pressure associated with asphyxia. Neonatal death, which occurs during the first few weeks of life, is often due to some cause acting during labour, e.g., dystocia, or even before the onset of labour such as syphilis, and it has to be considered along with the foregoing conditions.

Signs of Fœtal Distress.

The signs of fœtal distress *during labour* are slowing or quickening of the fœtal heart, the appearance of meconium when the presentation is other than breech, or the formation of a large caput. *After birth* the signs of distress are mainly respiratory. Thus the child may never breathe, and yet the heart beat for half an hour or more; again, respiration may be established but not satisfactorily, and fail in a few hours. In this class of case some intracranial injury is usually found. In a third type of case respiration may be apparently satisfactorily established and then fail gradually or even suddenly in a day or two, and in these cases hæmorrhagic pneumonia is often found post mortem.

Antenatal Examination and Care.

By proper antenatal examination much may be learned and efficient treatment established. From the *physical aspect* contracted pelvis, post-maturity, and malpresentation of the fœtus are the most important points to be guarded against. Early in pregnancy a full pelvic examination should be made, and the external and internal measurements carefully noted. This should include a careful measurement of the diameters of the pelvic outlet as in a number of cases unsuspected contraction may be present here, and may be the cause of complete perineal laceration (Blair Bell), the head having to pass entirely behind the ischial tuberosities. At the thirty-sixth and again, if necessary, at the thirty-eighth week the relationship between the fœtal head and maternal pelvis should be ascertained; this is done most accurately by the Munro Kerr method. If the disproportion be such that it is thought impossible for the head to come through the pelvis, Cæsarean section can be arranged for about term; if the disproportion be only slight, the patient or her friends should be warned that labour is likely to be prolonged and that instruments may be required. If the disproportion be of a medium degree, the best line of treatment is to induce premature labour just when the head can be engaged in the pelvis with slight difficulty, as estimated by the Munro Kerr method. It is of little avail to induce before the thirty-sixth week, as the chances of the child surviving are but slight: the later in pregnancy it can be delayed the better the outlook for the child. A breech presentation should be left alone until the eighth month when external cephalic version should be performed. Often anæsthesia is required for the satisfactory performance of this operation, and the head should then be pushed well down into the pelvis and an attempt made to keep the fœtus in its new position by applying a thick pad on each side of the head on the lower abdomen and fixing a tight binder round. If performed before the eighth month the malposition is likely to reappear as the fœtus is then liable to float round in the relatively abundant liquor amnii. In the rare cases where a face presentation is diagnosed before labour a determined attempt should be made by manipulation to flex the head and convert it into a vertex. If an occipito-posterior position be found it is an open question whether anything should be done at this stage. The great majority of these cases undergo long rotation spontaneously so that the occiput comes to lie anteriorly during labour. Before the onset of labour the best method of treatment is the two-towel method of Buist. The late J. W. Ballantyne reported considerable success with this manœuvre of prophylactic rectification and also with prophylactic version in breech cases. Post-maturity, accompanied as it is by enlargement and excessive ossification of the fœtal head, constitutes a grave risk to fœtal life in the same way as contracted pelvis. When the date of parturition has been carefully determined from the date of the last menses and of quickening, pregnancy should not be allowed to go on beyond 48 hours of that date in a primigravida or seven days in a multipara. Labour is most easily induced in these cases by the castor oil, quinine, and pituitary method of B. P. Watson, who records 95 per cent. of successes. Only rarely does a bougie require to be introduced, and then under strictly aseptic conditions.

Certain *toxæmic states* may also be diagnosed and treated during pregnancy. Syphilis in the mother during pregnancy should be treated as soon as diagnosed, irrespective of the period of gestation. Adams recommends intravenous injections of 20 cg. galyl, or a proportionate dose of novarsenobillon, increasing the dose to 30 cg. Intramuscular injections of mercury gr. 1 in emulsion are given at the same time. At birth a specimen of fœtal blood should be taken from the umbilical cord and a Wassermann test performed, and this test is to be repeated at six-weekly intervals on blood pricked from the heel.

Treatment of the infant is begun during the first week and consists of intramuscular injections of galyl, 2 cg. in glucose, repeated fortnightly, the dose being increased in time to 5 cg. Mercury gr. ¼ should be injected into the buttock and repeated weekly and, when two or three weeks old, hydrarg. c. cret., gr. ½, is given daily by the mouth. This treatment is to be continued until the Wassermann is negative, and is to be repeated if it subsequently again becomes positive. In the toxæmias of pregnancy treatment should be started when albuminuria is first noticed. If the patient comes under treatment only when the condition is advanced, the fœtus has probably already perished. Hence the important point is to get the patient under treatment early, and this can be done only if the urine and the general condition are examined at monthly intervals during pregnancy, and if she be told to report at once on the occurrence of headache, sickness, œdema, interference with vision, or hæmorrhage. She should at once be put to bed between blankets and surrounded by hot-water bottles; this diminishes metabolism and produces diaphoresis. The diet should be cut down relentlessly and if necessary reduced to water and imperial drink, milk being added later, and then fish, chicken, and meat as the condition improves. Eggs are to be prohibited throughout pregnancy. Magnesium sulphate should be given as required; it not only clears out the bowel, but also removes a large amount of toxin-laden fluid, and is very valuable in this respect. The action of the skin will usually be sufficiently stimulated by the blanket, hot-water bottles, and imperial drink. It is to be repeated, however, that fœtal life can be saved only if the case be treated in an early stage and if the patient be put under rigid supervision for the remainder of pregnancy. It is in cases of this nature that antenatal observation and treatment reach a high sphere of usefulness.

Prevention of Fœtal Death during Labour.

During labour much may be done to conserve fœtal life. While antenatal care and treatment are of the first importance in this respect, there is rather a tendency at present to forget that the most efficient antenatal observation and treatment will fail unless followed by equally efficient treatment during parturition. In this connexion Eardley Holland found that 60 per cent. of still-born fœtuses died *during* labour, while in a series of cases examined by the writer it was found that 71 per cent. had died under similar conditions.

During labour the factors to be considered are almost entirely mechanical and resolve themselves into two groups: (1) where there is some disproportion between the maternal bony pelvis and the fœtal head, and (2) where some fœtal malpresentation exists.

1. If the disproportion be extreme, as with a severely contracted pelvis, Cæsarean section should be performed if the patient be early in labour and if the conditions as regards sepsis are satisfactory. If the disproportion be only slight, probably forceps will be successful. But they should be applied only after sufficient time has been given for the head to mould to the maximum, and they are to be pulled on as gently as possible and screwed together just tightly enough to grip the head. If haste be avoided a fair proportion of these cases will be born spontaneously, and while it must be admitted that there is a definite risk to fœtal life in a prolonged labour terminated spontaneously, such risk is considerably increased by the application of forceps. Where the disproportion is moderate the difficulty is greatest, and in this class of case the widest choice of method —pubiotomy, forceps, Cæsarean section, and even symphysiotomy—is offered. Looking at the matter from the point of view of fœtal life, the best methods of delivery are the induction of premature labour under the conditions previously mentioned, Cæsarean section or pubiotomy, but for any of these to be of the fullest benefit the patient should have been under antenatal observation. It is of the first importance to see such a case as early as possible in labour. If seen early and before much examination and with the membranes intact Cæsarean section may be performed with safety to mother and child, while if she has been in labour several days it may be that craniotomy will be the only possible treatment.

2. In occipito-posterior presentations plenty of time is to be given, as we know that spontaneous long rotation occurs in the majority of these cases, and it is only when the posterior position is persistent that treatment is indicated. It must be remembered that turning the head alone is bound to fail, as this results merely in the twisting of the neck, and when the hand is removed the head slips back at once. Two methods are available: in one the head is rotated through a quarter or half a circle with the fingers of one hand

in the vagina, while the other hand grasps the anterior shoulder through the abdominal wall and rotates it in the same direction at the same time. The other method, devised by the late Lamond Lackie, consists of displacing the presenting part and inserting two fingers along one side of the head and behind the anterior shoulder, which is then rotated, usually easily, through a quarter or half a circle. The head usually follows easily and remains in its anterior position. Labour may then be allowed to go on spontaneously or be terminated by forceps delivery. Breech presentations, when seen first in labour, present many difficulties. The high proportion of still-births in these cases is brought about not so much by prolapse of the cord and pressure on the placenta, or even by premature efforts at inspiration, as by the pressure of the maternal soft parts on the after-coming fœtal head causing tentorial laceration and hæmorrhage as described above.

The points to be emphasised in the conduct of a breech case are (1) to keep up flexion of the head; (2) to avoid haste in delivery; and (3) to keep the exposed parts covered with a warm towel. Flexion is maintained best of all by suprapubic pressure, and this should never be relaxed after the buttocks are born. The best way to produce extension of head or arms or both is to pull on the legs in an attempt to complete delivery rapidly. Again, should the after-coming head be held up, it is justifiable to wait up to 20 minutes (Holland) for delivery rather than to deliver by one of the grips. During this period it is very necessary to ensure that the parts of the fœtus already born are covered by warm towels to prevent premature respiration. Only with this precaution attended to is it justifiable to wait longer than the few minutes usually recommended. Thus any delay in the birth of the after-coming head places us in a dilemma. If birth be hastened, intracranial injury is likely to be caused, and if an expectant attitude be adopted, premature inspiration may cause the fœtal air passages to become filled with vaginal mucus.

Probably a middle course is the best. The head is not to be rapidly extracted for fear of causing intracranial trauma, but up to 15 minutes may be allowed for spontaneous expulsion with firm suprapubic pressure. After that period the interference with placental circulation is likely of itself to stimulate respiration in the fœtus, and further delay should not be allowed. This is obviously a point of prime importance, and necessitates a considerable alteration in our ideas regarding the management of breech cases. Since rapid extraction of the after-coming head predisposes strongly to the production of tentorial laceration and hæmorrhage, the teaching in most of the text-books recommending extraction within a few minutes of the birth of the breech would appear to require modification in the direction indicated.

Ante-partum hæmorrhage and eclampsia are frequently associated with still-birth, but in these conditions the risk to the mother is so great that it does not appear justifiable to consider any measures except those in the maternal interest.

Asphyxia is the clinical condition usually associated with still-birth, and it is appropriate to consider here the effect of artificial respiration. Blue asphyxia is mostly due to lack of blood aeration, and seldom fails to respond to clearing of the air passages and gentle artificial respiration. White asphyxia is usually associated with cerebral injury due to intracranial hæmorrhage, and, with the best intentions, energetic artificial respiration is apt to be practised, especially if the heart is still beating. It is evident from what has been said that the only effect of such manipulation will be to tend to a further increase of the hæmorrhage, and so the last chance of life may be lost. In these cases, after clearing the air-passages, the fœtus should be wrapped up warmly and left absolutely at rest.

While the claims of the fœtus have been the primary consideration in this communication, in no case have the interests of the mother been prejudiced by any procedure recommended. Indeed, it can be said in general that what has been urged for the benefit of the fœtus is also for the benefit of the mother.

It is estimated that, on account of congenital defect, ante-partum hæmorrhage and similar conditions, 1 per cent. of still-birth is unavoidable. This is probably correct, and our duty lies in attempting, by all the means at our disposal, to prevent the occurrence of still-births in any individual case in which it is preventable.

FEMORAL HERNIA.

OPERATIVE TREATMENT BY ROUX'S METHOD.

BY FRANK HARVEY, F.R.C.S. EDIN.

THE radical cure of femoral hernia presents considerably more difficulties than that of the inguinal variety, owing to the difficulty in closing the crural canal satisfactorily. This is due to: (1) The rigidity of the internal and inferior boundaries of the crural canal, (2) the presence of the femoral vessels on the outer side of the canal. The question of whether femoral herniæ are congenital is disputed.

Sir Arthur Keith,[1] in his Mitchell Banks lecture on Nov. 1st, 1923, states that "at no point of the development of man or beast does an invagination of the peritoneum take place at the femoral ring." Hamilton Russell [2] (Melbourne) in 1902 and again in 1923,[2] propounded the saccular theory of hernia. He states that R. W. Murray [3] examined 100 bodies and found sacs in surprising numbers. My experience tends to prove that femoral hernia is not of congenital origin.

My series show 51 cases of adults, and only one in a child 5 years of age. These cases have all reported within a period of three months after the appearance of the swelling. This is contrary to my experience in inguinal herniæ where a large proportion of cases are known to have existed since birth.

Femoral hernia occurs more frequently, according to statistics, in women than in men, and rarely in children. Here my series of cases is in contradiction to the above statement, men having formed 28 of the cases and women 24. This variation may be explained by the fact that these men were engaged in heavy manual labour.

A great many varieties of operation have been devised for the radical cure of femoral hernia, but having tried many of the methods devised I have found that the results given by Roux's operation are by far the most satisfactory.

Fifty-two Cases of Roux's Operation.

In my series of 52 cases in which Roux's operation was performed, covering a period of 15 years (1905–20), 28 were males and 24 females. The youngest patient was a girl aged 5 and the oldest a woman aged 72. Forty-six cases have been traced and have replied stating that the hernia has not recurred, and pain is not complained of.

Technique of the Operation.

Roux's operation is a very simple one and is quickly performed. An incision is made parallel to the inner half of Poupart's ligament and along its lower border. The lower part of the incision is retracted so that the femoral canal is exposed. The sac is defined and opened. Omentum is often present and will usually be found to be adherent. All adhesions are freed, and it is frequently necessary to ligature and remove redundant omentum before returning it to the peritoneal cavity. Bowel, if present, is carefully examined where it has been in contact with the neck of the sac before it is returned into the abdominal cavity. The sac is pulled down with moderate tension, twisted to obliterate its lumen, and ligatured high up, the redundant portion being excised. A rectangular staple, which is made in various sizes, is now taken, and the points passed through the inner portion of Poupart's ligament. The inner limb of the staple passes just internal to the crescentic border of Gimbernat's ligament and the outer limb immediately internal to the common femoral vein. The staple is pressed firmly into the horizontal ramus of the pubic bone.

---

[1] Sir Arthur Keith: Brit. Jour. Surg., 1924, i., 469.

[2] R. Hamilton Russell: THE LANCET, 1902, i., 1519; Brit. Jour. Surg., 1923, xi., 150.

[3] R. W. Murray: THE LANCET, 1906, i., 363.

Roux's punch is now placed on the staple, which is gently hammered into the bone until the crural ring is obliterated. Care must be taken not to drive the staple in too tightly, or Poupart's ligament will be torn. The external wound is then closed with silkworm-gut sutures. Roux's punch is 5 inches long and has a groove in its lower end into which the staple loosely fits. Of the 46 cases, which I have traced, one (No. 38) recurred in six months. I removed the staple, and introduced a fresh one. There has been no recurrence, the patient having since worked as a coal-miner.

Conclusions.

I consider the following conclusions can be drawn from my experience of these 52 cases.

1. That Roux's operation is a simple and efficient one, and can be performed more quickly than any other operation for femoral hernia.
2. That the staple does not tend, in my experience, to become loose, and does not give rise to pain.
3. That right femoral hernia is more common than left. In my series of 52 cases, 37 were on the right and only 15 on the left side.
4. That the commonest type of femoral hernia is an epiplocele.

Queen Anne-street, W.

Clinical and Laboratory Notes.

AVULSION OF THE ANTERIOR SUPERIOR ILIAC SPINE TREATED BY OPERATION.

By A. G. ORD, F.R.C.S. EDIN.,
HON. ASSISTANT SURGEON, ROYAL PORTSMOUTH HOSPITAL.

THE cases of this injury here recorded are somewhat uncommon. Operative measures appear to offer by far the best hope of an early return to full activity and are, I think, quite justified in view of the surprising amount of disability the injury causes.

A boy of 17 was admitted with a history of limping and pain in the right thigh following on kicking a football hard with his right foot, and swinging round on his left leg.

Condition on Examination.—It was observed that there was some swelling but little bruising in the region of the anterior superior iliac spine. The limb lay in a position of slight flexion and internal rotation. There was no true shortening, and only slight limitation of voluntary movement at the right hip-joint in the directions of extension and external rotation. About 1 inch to 1½ inches below the iliac crest a lump about the size of a Kentish cob-nut could be felt, which was movable. Crepitus was easily elicited. A diagnosis of avulsion of the anterior superior iliac spine was made and confirmed by X rays.

Operation.—A U-shaped skin-flap was made of some 3 square inches in area over the swelling, and the fascia lata split longitudinally. The bony fragment was mobilised and approximated to the ilium by flexing the thigh. The periosteum was sewn together with catgut, and a doubly transfixed ligature of the same material around the whole gave additional security. The wound was closed in layers in the usual manner.

The patient was returned to bed with his thigh flexed, and it was only gradually extended, so that a position of full extension was obtained only on the ninth day, when the stitches were removed and the patient discharged. He was instructed to walk as much as he liked, but not run or kick. He came back to report in nine days, when firm union appeared to be established, and he was permitted to resume football, &c., and has had no further trouble.

Precisely similar details are found in another case of a boy of 17, but he was left-footed, and the injury was transposed to the opposite side. The same result was obtained by the same methods and in the same time. Subsequently, however, a case came to my notice which I have no doubt was originally one of avulsion of the iliac spine, which had been treated by strapping and recumbency. Although it was some seven or eight weeks after the injury when I first saw the case, yet there was still sufficient pain on extension and external rotation to prevent the boy recommencing his football activities. There was a mass the size of a hen's egg in the region of the spine, indicating excessive callus formation. It is certainly doubtful if he will play again this year, for the callus is soft, and may possibly be pressing on nerves.

It is a little difficult to explain the exact mechanism of the above injury. It would seem to be due to overaction of the sartorius when the thigh is semiflexed, adducted, and internally rotated, although it is surprising that such a comparatively weak muscle should be able to separate the epiphysis in this manner. Certainly the exact similitude of all three histories and the total absence of any direct injury support this hypothesis, but there must be other factors, for otherwise the injury would surely be a great deal more common.

TWO CASES OF SARCOMA IN CHILDREN.

By D. R. BLUNN, M.R.C.S. ENG.,
SENIOR HOUSE SURGEON, WALTHAMSTOW, WANSTEAD AND LEYTON CHILDREN'S AND GENERAL HOSPITAL, E.

THE following two cases of sarcoma seen in this hospital may be of interest :—

CASE 1.—A mother brought her boy, aged 4½, to hospital in March, 1924, saying that she had noticed discharge from his left ear for the last 12 months. He never complained of pain. Two polypi were found in the ear and removed with a snare. Peroxide drops and boric lotion were given for the treatment of the otitis media. The child did not come up again until the following June. On examination he was then found to be suffering from acute mastoiditis.

Operation.—The middle ear, antrum, and upper portion of the mastoid were found to contain pus and a polypoid fleshy mass, the whole of which was removed together with surrounding bone. On section the neoplasm proved to be a myxosarcoma. Radium treatment was given over a period of a week. Five weeks later a small swelling appeared below the site of operation, and gradually increased in size. The child showed signs of increased intracranial pressure. As the tumour increased, the lower jaw was pushed towards the opposite side and the left eye destroyed. The child died in October, with a tumour half the size of his head. It was not possible to obtain a post-mortem examination.

CASE 2.—A girl, aged 8, was sent in by the school authorities. The child said she had knocked her left cheek on the desk at school three weeks before. After this a small swelling appeared on the cheek and gradually increased in size. On examination a hard rounded swelling about 1¼ inches in diameter was found attached to the left malar bone immediately below the infra-orbital margin. The skin was freely movable over the swelling, but there was a mucocele caused by pressure on the lacrymal duct.

Operation.—A very vascular tumour was removed, and this proved to be an osteosarcoma on section.

Although a small swelling has recurred, radium treatment appears to be checking advance of the growth, as it is now six months since the operation.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

A MEETING of this section was held on Dec. 3rd, under the presidency of Mr. HERBERT J. PATERSON.

Diagnosis of Malignant Disease of the Thyroid Gland.

Mr. JAMES BERRY initiated a discussion on this subject. He intimated his intention to deal with it in a general way, chiefly from the clinical aspect, relating cases which were chosen because of the difficulties in diagnosis which they presented. Fortunately, malignant disease of the thyroid was not a very common occurrence. There were many difficulties in the way of a correct diagnosis of it. Some had allowed a malignant goitre, under the supposition that it was harmless, to grow to a considerable size before seeking medical advice; and in other cases a patient would be treated for months with iodine or with thyroid preparations without the suspicion having been entertained that the condition was other than an ordinary goitre. That was especially likely in districts where goitre was common; the practitioner was so familiar with ordinary goitre that he was apt to overlook the rarer and more serious disease when it occurred. One reason for this was that most malignant thyroid tumours caused no symptoms beyond the discomfort due to a growing lump in the neck. Alterations in health occurred only when the disease had reached an advanced—often an inoperable—stage. Pain, dysphagia, and dysphonia were, usually, quite late accompaniments—namely, after the growth had penetrated the capsule and when it had begun to affect the surrounding structures. These signs and symptoms might occur in the case of tumours of the gland which were not malignant—namely, those of inflammatory nature. In many cases, n the speaker's opinion, it was impossible to arrive at a certain diagnosis before operation. Malignancy might attack a goitrous tumour previously benign.

Thyroid tumours might have a wide area of contact with the trachea, and with the latter the thyroid capsule became quickly incorporated and so restricted movements. He pointed out that malignant goitre could not be moved on the trachea, as could innocent goitre unless definitely inflamed. The thyroid was n close relation with the recurrent laryngeal nerve and with the pharynx, hence the importance of paralysis of the vocal cords and dysphagia. These signs might occur when the tumour was but small if the disease began at the posterior part of the gland. Such cases usually, because of their symptoms, came irst to the laryngologist rather than to the general surgeon. The latter saw first the cases in which the disease formed a tumour on the front aspect.

An important factor in the diagnosis was the displacement of the carotid vessels; the malignant disease did not usually displace them to the same extent as did innocent goitre. When the malignant disease began in the anterior part of the gland and he tumour could grow forward, away from the recurrent laryngeal nerve and larynx, the patient was likely to be spared distressing symptoms. For hat reason it was possible that the malignant tumour might be allowed to attain a considerable size before medical or surgical advice was sought. In one case of the kind he dealt with, the tumour weighed 16 oz., and six months after the operation the patient died of recurrence of the disease.

The commonest degenerations of ordinary goitres were fibrosis and calcification. The statement had ecently been made in America that adenomata of he thyroid having a fibrous star-shaped centre were apt to become malignant, but Mr. Berry definitely dissented from that view. In his own series of 373 cases from which he had removed solid (not cystic) adenomata, only three or four eventually became malignant. These ordinary tumours should not be removed unless there was some definite reason for it, such as the production of pressure symptoms. Both fibrosis and calcification caused the occurrence of hard masses within the goitre, in this way enhancing the diagnostic difficulties already sufficiently great. Clinical histories were very misleading. A calcified thyroid tumour might exist for years without the patient being aware of it, especially if it lay behind the clavicle or the sternum.

The presence of a recently noticed hard lump in the thyroid region in middle age or later should always arouse the suspicion of malignancy, even in the absence of any other sign, though most such hard tumours were not malignant. Careful palpation helped greatly in the differentiation. Hæmorrhage was very common in thyroid tumours, but this was no indication of malignancy; indeed, among many cases of cystic adenoma and others in which bleeding occurred he had never seen any considerable spontaneous hæmorrhage within a malignant thyroid tumour. It was seldom that patients with innocent goitre complained of difficulties in swallowing; even when the pharynx and œsophagus were displaced it rarely was a permanent occurrence. But in malignant disease of this part, when the disease began at the back, dysphagia was often an early and important sign. Error was here also possible, however.

Mr. Berry said one of his main objects in bringing forward the subject was to draw attention again to the class of innocent thyroid swelling, which was frequently mistaken for malignant tumour. In the present day, when operations for thyroid disease were becoming increasingly safe and easy, there was a danger lest severe operations should be needlessly undertaken. He stated very definitely that removal of the whole thyroid gland should never be carried out, even for carcinoma of it. He had himself never done so, nor felt that he ought to have done it. He laid special emphasis on the fact that in the innocent variety of tumour there was nearly always present in the patient a waxy pallor, which indicated commencing atrophy. It was the beginning of what was seen more markedly in advanced myxœdema. This waxy pallor was practically always absent from the patient who had true malignant disease at that early stage before the growth had penetrated the capsule. He had been many times impressed by the apparent general well-being of patients who were suffering from even advanced and extensive malignant disease.

Around the hall were a large number of photographic enlargements of micro-photographs of different varieties of thyroid growth, and for several hours there had been on view many actual specimens from the Royal Free Hospital, which had been arranged by the pathologist to that institution, Dr. G. S. Williamson.

Discussion.

Mr. WILFRED TROTTER said that, to the practical surgeon, the subject divided itself into two groups: (1) The diagnosis of the nature of the condition being dealt with; (2) the diagnosis of the operability of the given tumour. Under the first of these he referred to carcinoma of the cervical œsophagus invading the thyroid gland. This presented a remarkably stable and constant clinical picture, and was very common. In its early stage it was essentially operable, but usually it was met with in a very misleading form. In most cases the first symptom was paralysis of a vocal cord, and the patient would at this stage deny that anything else was wrong. He showed sections illustrating how in a case of the kind the disease had come through from the œsophagus into the thyroid body, enlargement of which was the second symptom in this disease.

With regard to the diagnosis of operability, the task of diagnosis in connexion with malignant disease of the thyroid was not completed with the beginning of the operation. Diagnosis continued throughout the operation, the important matter being whether there was justification for continuing the operation. In his view malignant disease of the thyroid was not attacked with sufficient enterprise, and minor conditions encountered during the operation should not be too readily accepted as determining the diagnosis of inoperability. A further point in this matter of operability was the question of early recurrence. He had a patient with a papilliferous thyroid, which was operated upon as a benign tumour. Within six weeks recurrence took place, and it was somewhat firmly fixed to the tracheal wall, from which it had to be cut away. For fully ten years there had been no further recurrence. Kocher stated that cases of malignant disease in which the capsule of the thyroid was penetrated and in which glandular involvement occurred were very unfavourable. But the speaker had dealt with a youngish woman in whom there was a string of carcinomatous glands along the neck, and a mass in the right lobe of the thyroid, which at the operation was seen to have penetrated the capsule in several places. That was excised, and a systematic gland operation carried out, and the patient had remained free from recurrence to the present time, a period of 17 years.

Mr. A. J. **Walton** said no definite statement could be made which would be applicable to all varieties of thyroid tumour. He did not think a pathological classification was possible. He had had 13 cases which had been diagnosed as carcinoma in a series of 402 patients operated upon, or 3·2 per cent. malignant. If groups of cases seen in the out-patient department were included, the percentage would be reduced to 1·6. In goitrous districts the frequency of malignant disease of this gland was a little less than in non-goitrous regions. Usually it came on at about middle age; his youngest patient was a male aged 21, and his oldest a woman aged 79. Carcinoma might be present secondary to adenoma, and in these cases hyperthyroidism was an early symptom. There might be a cellular overgrowth within the capsule for a long time before the carcinomatous stage was evident. The only safe course was to remove them because of their liability to malignancy. Three symptoms, especially if combined, could be regarded as evidence of malignancy: (1) rapid growth, (2) irregularity of the surface of the tumour, and (3) its hardness. He made an important exception in the case of changes occurring in the gland in the course of pregnancy. No operation for goitre should be done on a pregnant woman unless there was some grave reason for it. Many thyroid changes ceased with the termination of labour. A suspicious sign of early malignancy was a radiating pain passing towards the ear; and stress should also be laid on the adherence of the tumour to the trachea.

Mr. T. P. **Dunhill** said that since he came to London from Australia he had operated upon 350 cases of goitre. These could be classed into three groups. In the first of them there was no doubt about the diagnosis when the patient was seen; there were lumps, usually irregular, sometimes involving the skin, sometimes the skin could be moved freely over them in parts. In some parts the tumour could be seen to fade away into surrounding tissues, and there was difficulty in breathing, perhaps in swallowing too, and the voice might be altered. In the face of such cases the surgeon felt helpless. In the second of his groups the nature of the case was not so obvious; the swelling was asymmetrical and less hard than in Group 1. The edges were fairly defined, and the breathing difficulty was greater than would have been suspected. The aid of the radiologist showed masses in the mediastinum. But even when such cases were felt to be malignant the patient should not be given the idea that nothing could be done for him. Sometimes the bulk of the tumour could be removed, and then the patient placed where he could receive skilled deep radiotherapy. In the third group he thought a correct diagnosis could only be arrived at with the aid of the pathologist. Five of his 350 cases had malignant adenomata. He urged a close working association between surgeon and radiologist, and a freer removal of early doubtful tumours, to avoid the risk of allowing a malignant growth in this region to develop unchecked.

Dr. G. W. **Nicholson** entered with some detail into a discussion of the pathology of the kind of cases under consideration. He thought tumours which were malignant in a portion only should be called parathyroid growths, though without implying that they arose in the parathyroid. It was safer to regard them always as malignant. He considered it impossible to diagnose malignant adenomata. He had seen three cases of squamous-celled carcinoma in which the growth probably originated in the thyroid gland. Two had keratinised freely.

Mr. **Zachary Cope** commented on the lack of exact knowledge in regard to the operability of these tumours, except in the case of the obviously hopeless ones, and here knowledge was not of much value. He narrated a case in a boy aged 10, in regard to whom the lump in the right lobe of the thyroid—which was removed—was reported to be "not typically malignant." But there were four recurrences, and the boy died. Surely four recurrences argued a very definite malignancy.

SECTION OF ORTHOPÆDICS.

A meeting of this section was held on Dec. 2nd, Mr. H. A. T. **Fairbank**, the President, being in the chair.

Mr. P. **Jenner Verrall** opened a discussion on

Sacro-iliac Disease.

He said that of the many branches of orthopædic surgery still imperfectly understood, the sacro-iliac joint was not the least important. When one considered that all the weight of the superincumbent body was borne on these joints and that they were all the time subjected to a shearing strain, and that the advantages of a bony ankylosis had been sacrificed to the needs of parturition and the necessity for shock absorption, one might well expect to find frequent disabilities in this region. Whatever the disorder of the joint the same clinical picture was presented—viz., a characteristic stance and gait, designed to spare the affected joint, with a tilting up of the pelvis on the bad side; the gait was especially striking in going upstairs, when the patient very carefully selects a painless position on the bad side, then swiftly swings the good leg on to the next stair and passes the weight to it; this procedure was in marked contrast to the process in hip conditions where the joint is painful in all positions. The history was usually vague, the onset being insidious, unless the pain followed pregnancy or some stooping strain. A very characteristic complaint was that of marked instability, the sensation of "falling to pieces." Since the joint was supplied by all the nerves near it, pain might be referred in many directions; the pain was increased by standing and walking, and especially by any sudden jar and by going upstairs. The condition produced a high degree of neurasthenia, with exaggeration of all symptoms, and in order to make a diagnosis it was necessary for the essential signs to be found. These included swelling, and possible abscess, over the joint, in the abdomen, the buttock, iliacus muscle, and pelvis; deep tenderness over the joint, to be distinguished from superficial tenderness referred from abdominal or pelvic lesions; the latter was usually rather lower down, being conveyed by the third sacral nerve. A conclusive test was the production of pain in the joint by prolonged compression, either of the crests or of the pubes. Hip movements were normal when the knee was flexed, but with an extended knee there was pain when the hamstrings began to tilt the pelvis. There was rigidity in the lumbar spine, but no true psoas spasm. The differential diagnosis must consider, firstly, strains in muscles and ligaments, which were common, and which did not produce the characteristic gait or the feeling of instability; and, secondly, the constant pitfall of referred pain. X rays did not materially help, as the joint was too tortuous for the antero-posterior view to show minor displacements.

The commonest form of affection was the toxic, due to chill, minor injury, or of insidious onset. Other joints were usually affected at the same time, as also was the case when the gonococcus is the causative organism. Tuberculosis of this joint was rare, severe, and fatal; abscess formation was very common, and might be the first indication of the disease. A condition of undue laxity of the articulation was not uncommon; it might be congenital, but more often followed repeated strain, or parturition. The restoration of this joint proceeded pari passu with the involution of the uterus, and might fail if the upright position was resumed too soon. Abnormal strain was also thrown on the joint by such things as a stiff hip or spine, traumata, or habitual bad stance. The acute case usually resulted from a bending strain, the upper end of the sacrum being forced backwards on the ilia; in chronic cases the sacrum tended to slip downwards and forwards. The treatment was operative, manipulative, or conservative. A severe arthritis demanded long immobilisation, from lumbar spine to hip, in a Thomas frame or plaster, with or without internal splinting. Mr. Verrall demonstrated a case showing excellent results from sliding a bone-graft right across under the erector spinæ from one posterior superior spine to the other; the bone might be taken from the tibia or ilium. The manipulation he preferred was that of full flexion, with subsequent support by some form of brace or elastic corset.

Treatment by Support.

Mr. J. B. **Mennell** expressed his gratification at finding sacro-iliac disease recognised by this Section; the majority of the cases were seen by physicians and diagnosed as sciatica, lumbago, neuritis, or chronic rheumatism. He showed a number of external supports of the type which he preferred, consisting of a large oblong back plate and a short, broad anterior plate, prolonged so that its ends lay just below the anterior superior spines, with three straps passing round from the front to the back and ending in front again; the highest strap was round the lower ribs, in order to get the top of the back plate above the lordotic curve, the middle one round the lumbar spine, and the third round the ilia. The breadth of the back plate depended on the nature of the strain; if there was forward torsion it was narrow to fit between the posterior superior spines, while the anterior plate pushed the sacrum backwards; if backward torsion was present the back plate was broadened. Referring to the puerperium, he suggested that more danger lay in sitting up in bed with an unsupported lumbar spine than in resuming the erect position too early, and advocated the old maternity binder, from waist to mid-thigh, as a support. He stressed the importance of examining the anterior aspect of the joint, as the sacro-iliac spot was close to McBurney's and confusion was liable to be made between them.

Treatment by Manipulation.

Dr. **Edgar Cyriax** maintained that subluxations of this joint were exceedingly common, as shown by a slight asymmetry of the bony points. He treated his cases by the usual method for subluxations—reposition by manipulation, a process which was painless, simple, and effective. Occasionally it required to be repeated, but in most cases one manipulation was sufficient and no after-treatment was required. Out of some 1500 cases he had only had half a dozen failures.

Mr. H. B. **Roth** described the manipulation he was accustomed to perform: he followed this up by strapping round the pelvis below the anterior superior spines, left on as long and as tightly as the patient could bear. Except in very severe cases requiring prolonged rest or operation, he obtained cure by this method in three to four weeks. He believed that the clinical picture of true sacro-iliac disease always began with sudden strain, never insidiously, and the patient, if asked to point to the site of the pain, would always put his thumb precisely over the joint.

Mr. R. C. **Elmslie** commented on the diversity of opinion as to the prognosis of the condition and considered that no real standard of diagnosis had yet been reached. He preferred to keep the term "lower backache," with which everyone was familiar, until a better one was found. There seemed no doubt that of this complaint there were many different causes, and some were cured by manipulation, some by support. He had found the painful spot very variable—over the crest, the erector spinæ, the lumbar or gluteal muscles, the side of the coccyx, &c., that over the sacro-iliac joint being rare. He submitted that there was no proof that the manipulations described had special action on the sacro-iliac joint; they might do many things with the lumbar and gluteal muscles. He quoted a case where a very obstinate pain of this nature had been cured by the processes of operatic dancing. He pointed out a characteristic flattening of the sacrum which accompanied the tilting of the spine.

Mr. G. R. **Girdlestone** described a case of prolonged and serious pain in which the insertion of a wedge-shaped piece of bone in the joint had failed to produce bony union owing to the rarefaction of bone which was practically always found in chronic cases. He had therefore repeated the grafting operation in the sacro-iliac joints combined with an arthrodesis of the symphysis pubis. At the present time there appeared to be commencing union.

The **President** said that it was clear that another discussion on this subject would be advantageous in two years' time; many points of operative procedure, such as the exposure of the joint, excision, &c., had not been touched on, and there was no agreement as to what was meant by the term "sacro-iliac disease." The diagnostic sign he found most useful was the production of tenderness in the joint by putting it on the strain by forcible flexion or extension. In treatment the important thing was stabilisation with lateral pressure on the crests, the sacrum being inaccessible to direct pressure.

Mr. **Verrall**, in replying, pointed out the importance of differentiating from ovarian pain, and maintained that in all true cases there was a tender point over the joint, often in association with other tender points—e.g., over the sacro-sciatic notch—due to pain referred along the nerves.

At the conclusion of the meeting Dr. **Cyriax** gave a demonstration of his method of manipulation.

SECTION OF OTOLOGY.

EXHIBITION OF CASES AND SPECIMENS.

A meeting of this section was held on Dec. 6th, Dr. **Kerr Love**, President of the section, being in the chair.

Malignant Disease of the Ear.

Mr. **Sydney Scott** showed skiagrams of a man, aged 27, who had malignant disease of the ear. About three years ago an epithelioma had been removed from the patient's scalp, glands being at the same time excised from the left side of the neck. There had since been several recurrences. The sections of the growth showed well-marked cell-nest formation, as reported by Mr. C. O. Davies, of Liverpool. The left pinna was now protruding, and an ulcerating mass blocked the meatus. Below the ear was an irregular mass, which adhered to the skin and was fixed. X rays showed that the apex of the mastoid had become absorbed. This appeared to be a secondary malignant growth of cervical lymphatics, with invasion of the auditory meatus and mastoid process.

Mr. W. H. **JEWELL** related the case of a woman who died of a fungating growth behind the ear. Two years previously a breast was removed on account of carcinoma.

Sir J. **DUNDAS-GRANT** showed some sections to illustrate the beneficial action of radium on endothelioma which was grafted upon angioma of the middle ear. The radium had produced a great change in the microscopical character, for there was now no sign of tumour cell structure, and there was not now the liability to bleed when touched.

Sir **WILLIAM MILLIGAN** said no great change should be expected in a squamous-celled growth such as this from the application of radium. It was a different matter in the kind of growth mentioned by Sir James Dundas-Grant, in which there was a fair quantity of fibrous tissue. In such a case as Mr. Scott's he advised surgical removal of the ear and a careful dissection of the lymphatic plexus, followed by diathermy. If, however, radium should be preferred, it should be applied by means of a dense " barrage " of small tubes charged with the salt.

Mr. H. V. **FORSTER** spoke of a case of epithelioma of the external meatus which he curetted and examined. There was a rapid recurrence, and he then did a radical mastoid operation. Though a good deal of relief followed this, there was a further recurrence, and he used a heavy dose of radium, but without any good result. He hesitated to employ diathermy because the disease had now implicated the bone.

Dr. **LOGAN TURNER** pointed out that the case alluded to by Mr. Jewell might not have been one of recurrence or metastasis, but possibly a new tumour altogether.

Mr. **SCOTT**, in his reply, showed how very rare it was for secondary cancer to appear on a neighbouring surface, such as on a contiguous lip of the vulva. Nowadays there was no need to fear that necrosis of bone would be produced by diathermy.

Mastoid Fistula Closed by Tube-flap.

Dr. **DAN MCKENZIE** showed a boy, aged 9, who, after a Schwartze operation, was left with a large wound which would not close. Success followed the use of a tube-flap cut from the neck. Dr. McKenzie said that if he should meet with the same difficulty in another case he would cut the flap from the forearm.

Temporo-sphenoidal Abscess.

Mr. T. H. **JUST** showed a man, aged 32, who for five years had had discharge from both ears. During the past eight weeks he had been giddy; also had suffered from headaches and rigors for six days. Mr. Just carried out a radical mastoid operation, when he found a cholesteatoma, perisinus pus, with a clot in the sinus; therefore the sinus was obliterated. There was a large fistula in the external semicircular canal. A day or two later there was violent headache; the patient was drowsy. Exploration of the temporo-sphenoidal lobe revealed a large abscess which was washed out and the residue aspirated. Recovery thereafter proceeded without interruption. Three weeks later a plastic operation to close the wound behind the ear was done, but in a day there was again violent headache. The wound was thereupon left widely opened, and recovery was uneventful.

The case was fully discussed, and Mr. Just was much commended on his success.

GYNÆCOLOGICAL HOSPITAL ACCOMMODATION IN LIVERPOOL.—Negotiations for better accommodation, long on hand between the Shaw-street Hospital for Women and the Samaritan Hospital for Women, have now been brought to a happy conclusion. For many years these institutions have struggled against great handicaps in the shape of the improvised nature of their premises. House after house has been taken in as the work expanded and as far as possible altered, but narrow passages, small doors, and a multiplicity of rooms remained. The corporation have now given a suitable site, and the gynæcological hospitals of the city should before long have ample and efficient accommodation to carry on their good work.

MEDICAL SOCIETY OF LONDON.

INSULIN IN THE TREATMENT OF DIABETES.

A MEETING of this Society was held on Dec. 8th, under the presidency of Dr. **EUSTACE M. CALLENDER**, when Dr. **GEORGE GRAHAM** introduced the discussion by reading a paper on the Present Position of the Treatment of Diabetes by Insulin, which appears substantially in full on p. 1265.

Prof. **HUGH MACLEAN** agreed that insulin had been a very great success in the treatment of diabetes, and when one met with an uncomplicated case one could say, almost with certainty, that the disease could be controlled by the intelligent use of insulin. He foresaw that the discussion on the best methods of using the new preparation would last for some years. The safest way was to observe what Nature did, and if that process was followed by the physician, he could not go far wrong. Keeping the blood-sugar within normal limits was comparatively easy with the patient in hospital, but when there was not this control it might prove a very difficult matter. It was difficult to so arrange matters that there would not be a small quantity of acetone in the urine. He did not quite agree that when a patient on a certain amount of carbohydrate stopped insulin there was a great danger in so doing. A patient who had been living as a result of the insulin he was taking might pass into coma, but in cases of medium severity he had seen the patient stop his insulin with no supervention of symptoms. He deplored the fact that the lay press had published far and wide the statement that when once insulin had been commenced it must be continued. Severe cases would naturally have to continue it, but that was not the fact in regard to moderate ones. He agreed that children made difficult subjects, and said that, in winter especially, when they had other complaints, they were liable to coma. A question which was now being asked was as to whether a diabetic person under treatment with insulin might be given medical permission to marry. Without expressing a decided view, he thought the psychological effect on the patient of a negative answer on this question might prove as harmful as permitting him to take the risk of matrimony. In the case of a medical man with the disease, who was taking insulin, he gave permission to marry. He was inclined to agree with the American authority who said that every patient under 40 suffering from diabetes of definite degree should have insulin; he did not mean those who simply had a defect of storage without evidence of lack of oxidation, as they might go on for many years. He referred to an extraordinary type of case in which there was definite renal glycosuria associated with definite diabetes. The patient passed almost into coma, yet the blood-sugar never went beyond 0·25, and later came down to 0·18. After 5 units of insulin she had definite symptoms of hyperglycæmia. In conclusion, he spoke of the definite tonic effect of insulin on some patients.

Dr. C. M. **WILSON** said the whole question of the value of insulin in diabetes was still sub judice. It was necessary to have series of cases treated in both ways and compare them He did not think that had yet been done, and even if it had, the time which could have elapsed since the introduction of insulin had not been sufficient for a judgment to be formed. In the present state of knowledge it was important to keep the blood-sugar within normal limits; and, that being so, was it best done by dieting or by the use of insulin? The general tonic effect of the latter made the problem a difficult one from the scientific standpoint. He hoped to hear something about the elderly diabetic who had eye symptoms. What had been the result of the use of insulin in these diabetics with diabetic retinitis? He had seen several such treated with insulin, and, on the whole, the results were somewhat disappointing. Elderly and young diabetics were usually keen on the treatment, but the middle-aged subject was apt to treat the matter lightly, and to be very reluctant to conform to the rules laid down for him. He agreed that insulin had been most valuable in the dramatic cases, such as the comatose, but there was still needed a good deal of careful observation and comparison.

Dr. E. G. B. CALVERT related his treatment of four selected cases of diabetes by insulin and gave the results. Winter and Smith, and others, showed that parathyroid enhanced the action of insulin, possibly by preventing the loss of calcium; similar beneficial effects occurred in Graves's disease, in which also there was a calcium loss. In cases without ketonuria or signs of acidosis, improvement after parathyroid was nil, but when acidosis or ketonuria was marked small doses did considerable good. He had also been noting the influence on metabolism of dextrose, fructose, sucrose, and starch when given with varying doses of insulin. These he stated at length, emphasising in this connexion the great value of orange-juice.

Sir JOHN BROADBENT referred to an extraordinary case which he had under his care last summer—that of a man who had 6 per cent. of sugar in the urine, and whose blood-sugar was 0·29 per cent. Two days of starvation did not materially reduce either. He was put upon insulin and the dose gradually increased to 25 units twice a day—i.e., 50 units per diem—taking at the same time only 10 g. of carbohydrate. Still his blood-sugar was 0·25, and the urinary sugar 4 per cent. He was then starved 72 hours. The urine thereafter became sugar-free, and he was again put on to 10 g. carbohydrate and had 10 units of insulin on this diet. He had remained sugar-free without insulin. His carbohydrates having been steadily increased until the quantity was now 40 g., he had since remained sugar-free without insulin.

Dr. W. LANGDON BROWN said much injury had been done to the cause of the treatment of diabetes by insulin by the unfortunate remark that people who started with insulin must continue with it for the remainder of their lives. He thought Dr. Wilson had taken an unduly pessimistic view of the outlook. He gave some particulars of successful cases in children treated by the preparation, and expressed his strong view that the outlook for diabetic patients was now much better than at any former time.

Dr. E. P. POULTON advocated, in some cases, splitting the daily dosage of insulin into three portions. He related a number of cases, and advocated the use of insulin, especially in young cases, as soon as the symptoms began to be manifest. In older patients the first definite effect of the insulin seemed to be the disappearance of the tiredness which had been so striking. Carrots and Jerusalem artichokes were much preferable to bread and oatmeal and potatoes.

Dr. GRAHAM, in a brief reply, said he regarded the retinitis as a part of the arterial condition in these diabetics. One reason why children were such difficult subjects was the risk they ran of acute infectious fevers, &c., and he did not know how this risk was to be diminished. With regard to marriage, permission to marry could not be so freely given to the woman as to the man, as the former had the very real risks attending pregnancy, the incidents of which were liable to place a great strain upon her in the presence of such a disease as diabetes.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING of this Society was held at Sheffield on Nov. 21st, Prof. A. DONALD, the President, being in the chair.

The discussion on the President's paper on the

Treatment of Mobile Backward Displacements of the Uterus,

adjourned from the previous meeting of the Society, was resumed (THE LANCET, Nov. 8th, p. 964).

Mr. W. W. KING (Sheffield) said that he only operated upon those cases of mobile retroversion in which the symptoms were relieved by replacement of the uterus and the use of a pessary. No woman objected to the use of a pessary for three months when it was pointed out that it was being used as a test as to the advisability or otherwise of operation. The use of this test eliminated the necessity for suspension operations in all but a very few cases. He considered that dyspareunia, sterility, and repeated abortions were, of themselves, indications for operation. He related cases of the cure of symptoms by sling suspension operations and their recurrence when the round ligaments gave way, so that the uterus again became retroverted. He took this to prove that retroversion did sometimes cause symptoms. He rarely undertook the operation of curettage except as a diagnostic procedure or in cases of retained products of conception.

Dr. LEITH MURRAY (Liverpool) tabulated his cases of ventro-suspensions during the three years 1921–23; they numbered 31 of a total of 593 abdominal operations carried out at the hospital for women. Of 12 cases nine were in married nulliparous women, mainly for sterility, and three were in single women and were decided on after exploration, an original diagnosis of mild inflammatory disease having been made. He was in complete agreement with the President, that there was little need for suspensory operations in nulliparous women, but contrasted the large number of cases for which the President recommended curetting with the rare occasions on which he himself considered this necessary. No single woman was curetted during the three years analysed, and only one married nulliparous woman. With regard to multiparous women he found much difficulty in appraising the more usual complications of child-bearing, such as subinvolution, mild appendage disease, and slight descent, in relation to symptoms. He considered that in mobile retro-displacements hyperæmia was intrinsic, and was not determined by the backward position. Curettage was the best treatment for subinvolution, except possibly in very big, heavy, tender, and retroflexed uteri, where he was of the opinion that a suspensory operation in addition to the curettage would more quickly lead to improvement. He preferred the term functional hyperactivity to "disordered action of the uterus" and subinvolution, in most cases, to "endometritis."

Mr. MILES H. PHILLIPS, who was unable to be present, had asked Dr. JOHN CHISHOLM to express the following views on his behalf. He was in agreement with Prof. Donald that the chief symptom of mobile retroversion was: (1) pelvic discomfort, varying in amount, and even in the same patient at different times. If neglected, frequently neurasthenia followed. The other troubles were: (2) sterility, (3) liability to abortion, and (4) dyspareunia, more especially when the ovaries were prolapsed. All these symptoms, if uncomplicated by other conditions, could be cured by replacement of the uterus, and its retention by a pessary or suspension operation. Mr. Phillips was astonished that cases of this kind occurred so rarely in the President's practice. The retroversion, however, was often of much less importance than some other conditions also present, for example: (1) gonococcal or other infection of the cervix, endometrium, myometrium, or appendages; (2) vaginal prolapse; (3) hypertrophied vaginal cervix. To overlook these and attend only to the retroversion was a frequent cause of disappointment. Often it was easy to tell what degree of attention the retroversion required in the inflammatory cases. But, in others, a pessary was first employed as a test before operation was advised. Mr. Phillips was satisfied that a retroversion did not cause endometritis. This was a statement made by people who looked upon any condition of hyperplasia as being caused by endometritis. He believed that congestion of the cervix and body of the uterus were produced by retroversion in many but not in all cases. This depended on the tone in the broad ligaments and utero-sacral folds. He was astonished that the

President had overlooked the paper by the late Sir W. Japp Sinclair on the engorgement and erosion of the posterior lip of the cervix in retroflexion. The speaker had on many occasions demonstrated that the condition disappeared after the uterus had been put in its proper position, a fact which pointed to some interference with the circulation. Again, drainage was interfered with by a retroversion in the puerperium and occasional cases of lochiometra resulted. In these the benefit of the semi-prone position for an hour or two, or even longer in bad cases, before the retroverted uterus could be reduced, was often seen. Mr. Phillips knew of three cases of acute abdominal pain produced by the retroverted uterus being caught and held by the utero-sacral folds. In two of the cases the surgeon at the operation (abdominal section) had considerable difficulty in dislodging the fundus, although there were no adhesions. In one of these cases the patient was a young nurse who was lifting a heavy bed.

Dr. FLETCHER SHAW said his views on this subject exactly coincided with those of the President, and, as he had on two previous occasions collaborated with him in papers upon this subject, there seemed no object in further reiterating his views, but it might be useful if he gave the reasons for his convictions. Many years ago, when resident surgical officer at St. Mary's Hospitals, he worked under two chiefs whose views were diametrically opposed on this subject. In one ward these mobile retroflexed uteri were always fixed up and in the other ward they were treated by curetting, just as an anteflexed uterus with the same symptoms would be, and in order to form his own opinion on the subject he had investigated a large number of these cases which had been treated by curetting. The symptoms were tabulated, the position of the uterus noted, and a questionnaire sent to each patient asking for the result in each separate symptom. These patients were then divided into two groups: anteflexed and retroflexed uteri. In each group the symptoms were the same, the only difference being the position of the uterus, and so if retroflexion was the cause of the symptoms it would be impossible for curetting, which left the uterus in the same position, to cure this group. The results showed, under every heading, that the group of retroflexed uteri had a slightly higher percentage of cures than the anteflexed uteri. That was many years ago, but quite recently he had made another investigation of a series of his own cases—163 altogether—and found the results exactly the same. The anteflexed uteri gave 75·7 per cent. of cures and the retroflexed 82 per cent. After this investigation it would be impossible to believe otherwise than that a mobile retroflexion did not produce symptoms, except in very rare instances. He thought that practically all the speakers in this discussion were in agreement with the President, who believed that retroflexion did not produce symptoms, but he granted that, like almost everything in medicine, there were a few exceptions, and most of the speakers who were supporting ventral fixation in this discussion seemed to be arguing largely from these exceptions, as they very seldom performed ventral fixation for simple mobile retroflexion.

Reply.

The PRESIDENT, in replying, said that as he had dealt with most of the criticisms which were really pertinent in the body of his paper he would not occupy more time. Some of the speakers had evaded the main point at issue—mainly the significance of retroversion and the criticisms of the congestion theory. He thought that he might say that the discussion as a whole showed that the feeling was against the indiscriminate performance of suspension operation.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The third meeting of the session will be held at the Miller General Hospital, Greenwich, S.F., to-day (Friday) at 8.45 P.M., when the Purvis oration will be delivered by Mr. Bellingham G. Smith on the Importance of Antenatal Clinics. This will be followed by a demonstration of the super-microscope by Mr. F. Davidson, illustrated by lantern slides.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

FURTHER SITTINGS.

(Continued from p. 1134.)

THE Commission resumed its sittings on Dec. 2nd, with Mr. H. P. Macmillan, K.C., presiding.

EVIDENCE OF EXECUTIVE OFFICERS.

Mr. H. F. Keene, the Chief Officer, Mental Hospitals Department, L.C.C., continued his evidence. He said discrimination was now made in regard to diet between manual and non-manual workers, the dietary being now less rigid than formerly. During 1923 3152 patients were admitted to London mental hospitals and 881 were discharged recovered. During 29 years 30,718 patients had been discharged recovered, and of these 9177 had been readmitted, one-third of them within 12 months of their discharge. Questioned by the Chairman as to the extent to which visiting committees safeguarded the interests of patients, he said he thought the present arrangements in respect to visiting committees did safeguard the patients' interests, and medical officers and chaplain and visiting ministers helped in that matter also. He said the population of the mental hospitals under the L.C.C. was 18,918, and that of the institutions of the Metropolitan Asylums Board was 5148. In the latter establishments there had been a diminution in the number of chronic and harmless lunatics of recent years.

Mr. W. G. Lobjoit, J.P., who is chairman of the Visiting Committee of Middlesex Mental Hospital, was strongly of the view that there should be two certificates for the detention of all cases, whether rate-aided or private. If, however, only one certificate was agreed to, it should be given by a doctor expert in mental diseases.

Mr. W. E. Lovsey, representing the Visiting Committee of the Birmingham Mental Hospitals, also urged the assimilation of procedure in Poor-law and private patients. He thought the present system of discharging patients worked without any injustice. Dealing with the question of allegations of ill-treatment, he said that in his ten years of experience disciplinary action had had to be taken in only one instance, that of a probationer.

EVIDENCE OF MEDICAL SUPERINTENDENTS.

Dr. Henry Yellowlees (medical superintendent, The Retreat, York) and Mrs. Constance Crosland (a member of the managing committee of that institution) were the next witnesses. Dr. Yellowlees explained that only private cases were taken at "The Retreat." Its foundation was due to the Society of Friends, and it was run on lines parallel with those of the other 12 registered hospitals. The hospital was not on the villa system, though it had two or three associated villas. There were 180 beds in the establishment, and the institution was mostly self-supporting. There were two medical officers in addition to himself. He thought that before a nurse finished her training for a permanent position in a mental hospital she should have had experience in a general hospital. In reply to questions, the witness spoke of the system followed should there be any complaints by patients. He preferred that the nurse should be present during the hearing of the complaint. A medical officer of experience and knowledge saw every patient every day, and he did not think any greater safeguard could be provided. Most of the complaints received had reference to roughness practised by the younger nurses. One was in respect to a female patient who had a very strong objection to taking a bath, and other patients who heard the struggles reported that torture was being carried out. Mrs. Crosland herself witnessed the next attempt, and saw it was necessary to carry the particular patient to the bath in a sheet, and the struggling was so violent that it was impossible to avoid dropping her. Dr. Yellowlees agreed, in answer to Earl Russell, that in some such cases an ordinary washing would suffice. With regard to patients' letters, the medical witness said that when he had been warned about letters to particular persons, he took care that any so addressed were not sent. Otherwise freedom was allowed in this matter. He spoke of the parole allowed, during which patients went shopping in the town or visited relatives. Sometimes relatives of patients from a distance took accommodation in the town so that such visits could be paid. He did not have to turn applicants away through lack of accommodation. Sometimes patients were sent there who might well have been treated elsewhere first, such as those with acute delirium, which might be recovered from in three or four days. In practically all the cases which came to "The Retreat" the boundary line into definite insanity had been undoubtedly passed, and it might be said that a proportion of them would not have crossed that boundary if proper treatment had been commenced early. It was a gradual process. He once declared, in an article, that it was only in a court of law that a man was declared to be sane on a Monday and insane on the Tuesday. In his institution recently he tested the feeling of all the certified patients, by means of a questionnaire, as to whether they definitely resented their detention. If an answer was at all resentful it was included in the affirmatives. The result was: Yes, 15; incoherent, silent, or doubtful, 46; No, 89. If, when a patient was ready to be discharged recovered, it was represented by the relatives that the conditions at home were not favourable for his reception and he thought this was not genuine, he discharged the patient, and so forced the relatives to do their part. In answer to a further question, the witness said he did not know of cases in which a discharged patient changed his medical attendant out of resentfulness for what had happened. Dr. Yellowlees detailed the equipment of the hospital for treatment purposes and the care exercised over the custody and administration of hypnotic and other drugs. He had not known of drugs, such as croton oil, being given for punishment purposes. The nurses in his institution were in the proportion of one to every two patients, but that was largely because some patients paid for the exclusive services of one, sometimes two nurses. Patients suffering from epilepsy or from the gross congenital defects were not received at the institution. About half the admissions in any one year were voluntary boarders, and not certifiable. In answer to Sir David Drummond, he admitted it would be an advantage to have a woman doctor on the staff of a mental hospital; many of the female patients expressed a preference for a woman attendant.

Dr. J. G. Porter Phillips (physician-superintendent of Bethlem Royal Hospital) was the next witness. He was accompanied by Mr. Lionel L. Faudel Phillips, the governor of the hospital. He said the voluntary boarder system had been in vogue at Bethlem for 40 years, and from the careful observations made by his predecessors and himself he considered it was a system to be encouraged in every way. Nearly 40 per cent. of the inmates were voluntary patients, and the straightforward voluntary patient did not cause trouble; he knew he was ill, and sought advice. Quite 70 per cent. of the patients were admitted on a free basis, the expense being met by a charitable foundation. Among voluntary patients he had had a recovery-rate as high as 50 per cent. Quite a number were restored to society without certification, and he advocated an extension of this system of voluntary residence. For all patients he would like to see operative a temporary "observation order," with some necessary power of control, but short of that attaching to certification. This would probably result in a reduction in the number of certified patients. A certain number of cases could be adequately looked after and treated in a general hospital, not in the general wards, but a separate wing or special wards could be set apart for them. Their mental state might be causally associated with acute physical illness, and then everything was to be gained by retaining the atmosphere of a general hospital; certainly the patients had more confidence in themselves. In the mental out-patient department at St. Bartholomew's Hospital the patients derived great benefit, but they sometimes retrogressed between visits. That hospital had no wards for mental cases.

Mr. Faudel Phillips spoke of his work at Bethlem Hospital and his investigation of complaints. In ten years he had not seen a patient whom he considered to have been wrongfully detained. He expressed himself as strongly in favour of the system of voluntary patients. The stigma attaching to certification was a very real thing, and the very name "Bethlem"—corrupted to "Bedlam"—was an obstacle to the hospital's work. Perhaps 99 per cent. of the patients on leaving thanked the doctors and the committee for what had been done for them. In reply to Sir Humphry Rolleston, Dr. Porter Phillips admitted it would be a great help if there were a system whereby a patient agreed to his detention for such time as the doctor decided was necessary.

Reviews and Notices of Books.

ANAPHYLAXIS AND SENSITISATION.

By R. CRANSTON LOW, M.D., F.R.C.P., Assistant Physician for Diseases of the Skin, Royal Infirmary, Edinburgh. Edinburgh: W. Green and Son, Ltd. 1924. Pp. 384. 25*s.*

THIS volume is a reproduction of a thesis submitted by the author for the degree of M.D. of the University of Edinburgh, and we are not surprised to learn that it gained a gold medal. Some idea of the labour involved in its preparation may be gathered from the fact that the bibliography of references at the end occupies 75 pages, roughly one-fifth of the whole volume. The value of such a complete bibliography in itself is, of course, very great, and the author deserves the sincere thanks of his fellow-workers for its compilation; but the chief merit of the book lies in the impartial way in which he has collected the facts established and the theories put forward by others, and incorporated with them results of his own investigations and his own views. It is, of course, mainly with reference to diseases of the skin that the problems of anaphylaxis and sensitisation are considered, but the first two chapters form a good survey of our present knowledge of the whole subject. Serum sickness is generally regarded as a true anaphylactic phenomenon, and the author considers that the natural hypersensitiveness to foods, animal emanations, and plants which characterises certain persons, and is manifested by urticarial rashes, gastro-intestinal disturbances, hay fever, and asthma, is also of an anaphylactic nature. This view has, of course, been warmly contested, but the objections to it do not bear analysis. The hereditary transmission of this hypersensitiveness, which has also been denied, is a striking point, and may correspond to the transmission of sensitiveness to their young by experimentally sensitised animals.

After these two introductory chapters, various skin diseases, in the production of which sensitisation may be assumed to play an important rôle, are considered. Urticaria of internal origin is in all probability always a true anaphylactic phenomenon, as the observations of Widal and others would suggest, but the various drug-rashes can hardly be so regarded, since experiments on animals, with a view to producing in them active and passive anaphylaxis to drugs, have proved negative with a few doubtful exceptions; it is, however, possible to desensitise a person to a drug by preliminary small doses or by prolonged administration of minute doses. In the chapter on the erythemata and purpura, the author rightly takes the view that erythema exudativum multiforme is a clinical entity, and should be separated from the erythemato-urticarial eruptions that may follow the taking of drugs, of certain foods, and the administration of foreign sera. There would seem to be no doubt that true recurrent erythema multiforme is due to sensitisation of the skin to a streptococcus, possibly a specific strain which cannot, however, be at present defined by laboratory tests. Dr. Low states that "erythema multiforme is not associated with true rheumatic fever, and any rheumatic eruptions are possibly due to absorption from the throat or other septic focus." This statement raises the question: What is true rheumatic fever? That erythema multiforme occurs not infrequently with attacks of typical acute rheumatism and rheumatic endocarditis is unquestionable, and we have seen it usher in a fatal malignant streptococcal endocarditis in a child with old rheumatic valvular disease. We must admit that we cannot see any reason for separating acute rheumatism from other forms of streptococcal arthritis and endocarditis, although it may be admitted that different strains of streptococcus are probably responsible for the different types of cases met with. The same question arises, of course, with regard to erythema nodosum, the association of which with acute rheumatism has been affirmed by some and denied by others. It can hardly be doubted that the usual form of erythema nodosum is due to streptococcal infection, the lesions bearing the same relationship to this infection as erythema induratum bears to tuberculosis; streptococci have actually been demonstrated in the lesions and have been found in the blood during an attack. There is no more reason to suppose that it is caused by a specific organism other than a streptococcus than in the case of acute rheumatism, and Rosenow's claims to have isolated a specific diplo-bacillus require the confirmation that is singularly lacking in nearly all his work on focal infection. It is obvious that this, the common form of erythema nodosum, is the deep or subcutaneous variety of true erythema multiforme; the two may appear simultaneously, and cases have been seen in which recurrent attacks of one or the other recurred over a period of several years until the tonsils were enucleated and an autogenous streptococcal vaccine given.

At the same time nodose erythema and eruptions of the erythema multiforme type may occur in persons sensitised not only to infections other than streptococcal, but to sera and certain drugs. Thus the evidence that an erythema nodosum, distinct from erythema induratum, may be a manifestation of tuberculosis is very strong, and probably the same is true in leprosy and syphilis; it is also a rare form of trichophytide, and, of course, nodular erythematous lesions may be produced by iodides. To sum up, although erythema multiforme and erythema nodosum in their most characteristic forms may be regarded as specific entities and due to streptococcal infection, similar types of cutaneous reaction may be caused by sensitisation to other toxins. In a short chapter on dermatitis herpetiformis and pemphigus, Dr. Low suggests that the former is "due to sensitisation of groups of cutaneous nerve-endings to some bacterial protein from the bowel." He is also inclined to consider pemphigus vulgaris as having a similar cause, but in this disease there is probably a general infection of the blood and internal organs, whereas in dermatitis herpetiformis the infection is confined to the intestines. He refers to the bacteriological work of Radaeli and Tominasi, but does not mention the more recent observations of F. Eberson.

After dealing with sensitisation in tuberculosis and syphilis, Dr. Low contributes a most valuable chapter on sensitisation and immunity to fungus infections. The important work of Jadassohn, Bloch, Rasch, Sutter, and others on the trichophytides has not been given the recognition it deserves in text-books of dermatology, and we welcome the very full account that is here provided, not only of the observations of the above authors, but also of Dr. Low's own investigations in this subject. The study of the mode of production of these trichophytides and the tuberculides, and of the close analogy that exists between the two, is one of the most fascinating subjects in dermatology, and has thrown much light on the pathogenesis of skin eruptions in various infections. The chapters on dermatitis venenata, in which the author's well-known experiments on himself with *Primula obconica* are described in detail, and those on eczema and focal infection, afford an admirable review of these subjects, which are almost of as much importance to the general physician as to the dermatologist. We are delighted to find at last an intelligent account of the pathogenesis of eczema, seborrhœic dermatitis, and seborrhœic eczema, and with Dr. Low's views we are for the most part in entire agreement. Eczema, of course, is merely a reaction of the skin dependent on epidermal sensitisation, and this sensitisation may be due to an external irritant or to a toxin absorbed from within. The actual sensitising agents are numerous and varied; thus they may be chemical, of animal or vegetable origin, or bacterial. The confusion between so-called seborrhœic dermatitis and seborrhœic eczema is quite unnecessary; the former term should be applied to the group of eruptions that occurs in seborrhœic persons, in which the inflammatory changes in the skin are entirely due to the active growth of the seborrhœic organisms, the staphylococcus, and the "bottle-bacillus" (it is doubtful whether the microbacillus ever causes inflammation, although it is the cause of the comedo of acne); these eruptions are exactly comparable to tinea circinata. When, however, sensitisation of the skin to the staphylococcus takes place, an eczema results and the eruption is no longer due merely to the parasitic growth in the skin of the staphylococcus. Seborrhœic dermatitis is easily cured temporarily by local applications, but seborrhœic eczema is intolerant of such treatment, and, the skin being in a sensitised state, the eczema is made worse by their use.

The last two chapters deal with tests for cutaneous hypersensitiveness and non-specific desensitisation. The cutaneous protein tests, which have been much in vogue of late, are discussed in detail. With regard to non-specific desensitisation, various methods are considered—e.g., intravenous injections of typhoid and other vaccines, peptone, intramuscular injections of milk, and autosero- or auto-hæmotherapy. Dr. Low gives details of cases treated by himself with peptone and with milk. Prurigo, psoriasis, seborrhœic eczema, and generalised exfoliative dermatitis were the principal conditions treated. With the exception of one case of psoriasis, in which exfoliative dermatitis supervened, and which reacted very well to injections of milk, the results were not good. No cases of seborrhœic eczema treated by injections of peptone are, however, recorded, although the author's colleague, Dr. Frederick Gardiner, has testified to their undoubted value in this condition. On the whole, however, non-specific protein therapy and auto-hæmotherapy have not yielded the results that were at one time looked for; occasional brilliant successes have been recorded by a number of authors, but both methods are very inconstant and usually disappointing.

Dr. Low's book deserves a very warm reception from the whole medical profession; it is the result of many years toil and is a great credit to the Edinburgh School of Dermatology, which, under the inspiration of Sir Norman Walker, has deservedly earned its reputation for the excellence of its teaching and the sanity of its views. The volume is very well produced, the illustrations, though few in number, are well chosen, and the printing in large type of the names of the authors referred to is a welcome innovation.

Recent Advances in Medicine.

Clinical, Laboratory, Therapeutic. By G. E. Beaumont, M.A., D.M. Oxon., F.R.C.P., D.P.H. Lond., Assistant Physician to the Middlesex Hospital, and to the Hospital for Consumption and Diseases of the Chest, Brompton; and E. C. Dodds, M.B., B.S., B.Sc. Lond., Chemical Pathologist to the Middlesex Hospital, Bland-Sutton Institute of Pathology, and Lecturer in Biochemistry in the Medical School. London: J. and A. Churchill. 1924. Pp. 292. 10*s.* 6*d.*

It is with increasing difficulty that the physician is able to keep pace with the recent advances in biochemistry and other departments of scientific medicine and to apply them in his practice. Only those who have access to a wider field of literature than the ordinary practitioner, or are in the fortunate position of being able to interchange ideas and information with workers in different countries, can hope to be leaders in the application of such discoveries. As the outcome of the combined efforts of a physician and a biochemist who are engaged daily in the routine application of the newer methods this book is of exceptional value. The first chapter deals with the chemical analysis of the blood by the methods of Folin and Wu. It includes also an account of MacLean's method of blood-sugar determination, the estimation of the fragility of the red cells, the cholesterol content, and a section on blood-grouping. Succeeding chapters deal with renal function tests and their practical application; tests for glycosuria and acetone bodies; an account of acidosis and methods for its determination, with a section on diabetes mellitus and its modern treatment. The investigation of pancreatic, hepatic, and gastric functions is dealt with in detail, and methods for determining basal metabolism are given with their interpretation. A chapter is devoted to the investigation of the heart, and includes an account of the polygraph, electrocardiograph, and blood-pressure apparatus, to which is added some notes on digitalis (including Eggleston's method of administration), strophanthus, and quinidine. The electrocardiograph is described briefly, although little is said as to how to use it. The interpretation of electrocardiograms is more fully dealt with, with the aid of 13 examples from Lewis's "Clinical Electrocardiography." Further chapters include artificial pneumothorax, the protein reactions in hay fever, asthma, and urticaria, Schick test for diphtheria carriers, the diagnosis of the enteric group of infections, and the examination of the cerebro-spinal fluid.

In fewer than 300 pages Dr. Beaumont and Dr. Dodds have thus collected a mass of information of high value; often they have added comment of great excellence, and there are interspersed accounts of several recent therapeutic advances which are not easily accessible. In these chapters are to be found complete technical descriptions of nearly every laboratory test of proven utility, although we miss any description of methods for estimating the calcium content of the blood, and of the tests for mucin and pus in the urine. A book containing a description of the macroscopic Widal test and the cutaneous tests for asthma should perhaps also give the technique for the quantitative von Pirquet reaction, and since methods of blood-grouping and estimation of corpuscular fragility find a place, a subsequent edition might well include an account of modern methods of counting and measuring the blood corpuscles. The chapters are enriched by comments in which the value and limitations of the various tests are discussed, and in many cases, particularly with regard to renal, pancreatic, and hepatic function and basal metabolism, these comments will be found of great utility.

Perhaps the authors have attempted too much, aud many of the therapeutic measures described can be found in other easily accessible works. But it is a real achievement to have brought together successfully within the compass of a small book all the important recent advances in practical medicine. The volume should find a place in every clinic where attempts are made to keep abreast of the times in laboratory methods. It will also make a strong appeal to the practitioner, who, though he may have no opportunity of carrying out tests for himself, must have sufficient knowledge of the technique involved and of the interpretation to be sought from their results to satisfy himself and the patient that they are worth the inconvenience and expense involved.

Diseases of the Skin.

Hautkrankheiten (Mracek-Jesionek). Fifth edition. Edited by Dr. P. Mulzer, Professor of Dermatology and Syphilis at the University of Munich. Munich: Lehmanns Verlag. 1924. With coloured plates. Pp. 260. M.22.

A copiously illustrated text-book of dermatology has two main advantages: (1) It recalls the visual memory of cases formerly studied in the skin out-patient department, and (2) it records actual cases, and affords to dermatologists of other countries an opportunity of revising nomenclature and keeping it up to date. Coloured plates, therefore, tend to international standardisation, and are for that reason greatly to be encouraged in dermatological literature. Several different processes appear to have been utilised in the coloured reproductions of this book, and the results are therefore very uneven. The most pleasing and true to nature are the group of colour-photographs towards the end of the book, dealing with tinea in its effects in various situations on the body and scalp. These plates are not original, being reprints from an excellent text-book, "Fadenpilz-Krankheiten," on this subject, by R. O. Stein-Henning. Intermediate in accuracy and artistic value are some coloured reproductions of museum moulage specimens, while very crude and sometimes even misleading are the old-fashioned prints from original water-colour sketches. These are doubtless relics from a former edition, and might well have been omitted. There are also a number of good plain photographs, which to the trained eye, at any rate, are of more use than the last named. Most of the plates are described from actual cases, which are reported, in some detail, on the opposite page. This seems an excellent plan, and one which adds greatly to the interest and educative value of the letterpress. Treatment is discussed in general terms in a dissertation of 38 pages at the beginning of the book. Under the different diseases it receives more detailed consideration, and differential diagnosis is also shortly specified. The arrangement of the text could be improved. The subjects appear to have been taken haphazard, and there is no attempt at classification on modern lines. This necessitates a constant and tiresome reference to the index, and entirely obviates the possibility of consecutive reading.

On the whole this book can be recommended both to students and practitioners with a knowledge of the German language as reaching a fairly high standard as a text-book.

Toxicology, or the Effects of Poisons.

By Frank P. Underhill, Ph.D., Professor of Pharmacology and Toxicology, School of Medicine, Yale University. Philadelphia: P. Blakiston's Son and Co. 1924. Pp. 292.

This manual of toxicology, intended as the preface states for medical students and physicians, has many excellent features. The material is well and concisely put together, and each poisonous substance is treated systematically as regards general properties, symptoms, fatal dose, post-mortem findings, and treatment.

The author, at the outset, states that no attempt has been made by him to enter into details of the isolation and identification of poisons. The word "toxicology" may be taken to mean the science of poisons, covering a wider field than the subtitle. The omission of any analytical detail is unfortunate. It is doubtless true that the student of medicine and the physician are not expected to have skilled knowledge of this branch, but they should at some period of their academic career have mastered the general principles. In cases of poisoning where, for example, a bottle is found beside the patient, the knowledge of a few simple tests for some of the commoner poisons may enable the physician to gain an idea of the nature of the poison, which will greatly assist him in his diagnosis and treatment. Though omitting details of this sort the author does not hesitate to give in full the constitutional formulæ of a number of the complex organic drugs, including the alkaloids, many of which are still speculative. This branch of the subject is intriguing, but it is rather overwhelming. Incidentally the graphic formulæ for antipyrin and camphor are incorrectly rendered.

The sections on treatment are good, and the author has been wise in omitting the older traditional antidotes which have little, if any, practical value, such as ferric hydroxide in arsenical poisoning. In carbon monoxide poisoning mention is made of the value of the inhalation mixture of carbon dioxide and oxygen in order that alkalosis of the blood may not occur, and it is pointed out that transfusion of blood, if it is to be of value, must be done at once.

At the end of each subject references are given to journals and books, most of which are recent. It is satisfactory to find this, since too often in works on toxicology and forensic medicine cases of half a century ago are depended on for details, and when such cases are investigated they are often of doubtful value.

Altogether a useful manual.

UNSCIENTIFIC ESSAYS.

By FREDERIC WOOD JONES, M.B., D.Sc., Elder Professor of Anatomy in the University of Adelaide. London: Edward Arnold and Co. 1924. Pp. 208. 6*s*.

THIS book of essays is concerned with "the expression of things too trivial and too inexact to be reckoned as scientific." Prof. Wood Jones indeed plays happily, like a child "tidying" his mother's silks, with the confused medley of skeins and reels in Nature's work-basket. He makes no methodical attempt to disentangle the threads, but, picking up a strand here and there, he unravels it from its fellows and follows it far enough to indicate clearly its origin and probable destination; then he drops it, intrigued by the colour, quality, or texture of another strand. Thus he passes from the reasons why the iridescence of a patch of kerosene excites less rapture than that of the wings of a dragon-fly to those why coconuts never fall on a man's head; from the mystery of phantom tigers to the place of faith-healing in modern medicine. All must delight in the delicacy of his touch, and in the Christmas holiday season many will drop all other preoccupations to sit with him in Malaya, on the Banka Strait or on a coral island, and play with him the game at which his prowess is so infectious and so stimulating.

THE SITE OF THE GLOBE PLAYHOUSE, SOUTHWARK.

Second edition, revised and enlarged. By W. W. BRAINES, B.A. Published by arrangement with the London County Council. London: Hodder and Stoughton, Ltd. 1924. Pp. 112. 6*s*.

TWENTY-FIVE years ago the late Sir Walter Besant wrote: "The site of the Globe theatre is generally allowed to have been at a spot 150 feet south of Park-street, close to the Southwark Bridge-road and on the east of it." Ten years later this theory was attacked by a university professor from Nebraska who believed that Shakespeare's theatre was built on the north side of Park-street. Since Dr. C. W. Wallace published his articles in the *Times*, a controversy between the partizans of the North and South theories has raged intermittently, till it may now be said to have received its coup de grâce by the publication of the second edition of "The Site of the Globe Theatre." In this enlarged and revised edition of the first volume published three years ago, Mr. Braines has sifted every particle of evidence obtainable and has succeeded in demolishing one by one the arguments advanced by Dr. Wallace and Mr. George Hubbard in support of a north side site. With meticulous care he has examined the documents relating to the properties on both sides of Park-street, then called Maid-lane, the evidence of the early views and the statements of the various historians of Southwark, and the conclusions deduced in favour of the south side site may be taken as final.

The somewhat chaotic method of arrangement, by which the book ends on page 62, and then is carried on in six appendices for another 46 pages of equally interesting material, rather detracts from its value for a lay reader, but the student of old London, among whom a considerable number of medical men take a place, will find Mr. Braines's work extremely useful. The book is enhanced by 17 excellent illustrations, including reproductions of the Agas, Visscher, Merian, and Hollar views, and some interesting conjectural reconstructions by Mr. G. Topham Forest, architect to the London County Council, of "this unworthy scaffold . . . . this wooden O," on which Shakespeare once tried to represent the vasty fields of France.

PHYSIOLOGY.

Principles of General Physiology. Fourth edition. By Sir W. M. BAYLISS, M.A., D.Sc., LL.D., F.R.S., late Professor of Physiology in University College, London. London: Longmans, Green and Co. 1924. Pp. 882. 28*s*.

DURING the long illness of the late Sir William Bayliss the preparation of a fourth edition of his famous book was undertaken by various friends as a tribute of affection. Their earnest hope that he would recover, and be able himself to undertake a further edition in course of time, was disappointed. Everyone knows that this book marks an epoch in the history of the development of physiology; it is an indispensable reference book. In these days of specialisation, all must deplore the loss of a man whose knowledge was so wide and understanding so deep; the learning which could have produced from one individual such a comprehensive survey of physiological principles was indeed of no common order. Some 25 collaborators have assisted with the revision of the present edition; yet all these specialists felt satisfied that little alteration, beyond bringing a few details up to date, was required. The work will long remain a monument to one of our greatest scientific minds.

Fundamentals of Human Physiology. Third edition. By R. G. PEARCE, B.A., M.D., formerly Director, Medical Research Laboratory, Lakeside Hospital, Cleveland, Ohio; and J. J. R. MACLEOD, M.B., D.Sc., F.R.S., Professor of Physiology in the University of Toronto, Canada. Assisted by Dr. NORMAN B. TAYLOR. London: Henry Kimpton. 1924. Pp. 349. 18*s*.

THIS is a thoroughly sound introduction to elementary physiology, which students of medicine would profit by reading. It gives much really modern information in a clear and simple fashion, and is well produced. Our only fear is that the high price of the volume, which is perhaps in part due to the insertion of some coloured plates which might have been dispensed with, may prove an obstacle to the sale of the book in this country.

THE LANCET.

LONDON: SATURDAY, DECEMBER 13, 1924.

PAYMENT FOR RESEARCH.

A Berlin patent agent recently showed a list which he had compiled of famous scientists who were proprietors of bacteriological patents, telling a meeting of German naturalists that a decision of the German Patent Office had made it possible even to patent the vital processes of nature. This list might interest those who feel, rightly or wrongly, that there is some sort of taint about the word "scientist," put forward though it was 85 years ago by the learned Dr. Whewell. In the current issue of *Nature*, where the word and its associations are fully discussed, Prof. Ray Lankester implies rather unkindly that the word has acquired the significance of a charlatan's device. Professional feeling in Germany was at one time bitter on the subject of E. v. Behring's large income from biological patents, wisely though he may have spent it, and there were widespread murmurs at the enhancement by royalties of the cost of salvarsan and its congeners. It is a little unfortunate that scientific results should require to be protected against commercial exploitation by the taking out of letters patent, and while the medical profession is under a debt to many reputable houses for the readiness with which they take up and apply the findings of recent research for the benefit of the public, it is also true that there are others who avail themselves of any striking line of work, however tentative, and commercialise it in no other interest than their own. We have recently become accustomed, in the case of insulin, to the taking of measures for the protection of scientific results against unworthy exploitation. In the September number of the *Journal of Biological Chemistry*, in connexion with a paper by H. Steenbock and A. Black on "The induction of growth-promoting and calcifying properties in a ration by exposure to ultra-violet light," there appears the following footnote: "To protect the interest of the public in the possible commercial use of these and other findings soon to be published applications for Letters Patent, both as to processes and products, have been filed with the United States Patent Office and will be handled through the University of Wisconsin."

The proper reward of scientific endeavour is a matter on which very divergent views have been held. The National Union of Scientific Workers of Great Britain has made a pronouncement upon it in a recent report of its Research Committee entitled "The Encouragement of Fundamental Research." This Committee divides research into "practical," that is to say, undertaken primarily with a view to results of a practical nature, and "fundamental," that is to say, research undertaken without any immediate expectation of such results—and it is with the latter that the report is concerned. Fundamental research is of value to the community for the obvious reason that it does often lead to practical results, but quite apart from what may be called its utilitarian aspect such research work is desirable for its own sake. It tends to produce a broadmindedness and to develop the intelligence of the individual engaged in it: research does, in fact, promote that inquiring turn of mind which is such a desirable quality of citizenship. How, then, is fundamental research to be encouraged? On the question of rewarding successful research by money prizes or by granting patent rights the report before us is emphatic in its disapproval. Payment by results is, in general, wasteful—this sums up in a sentence the Research Committee's opinion. Special grants in hard cases where investigators have obtained their results only by personal sacrifice are condemned on the ground that the real remedy is to prevent the occurrence of the hard case. Prizes are criticised because they offer encouragement often to those who are in no need of them. The granting of patents is only possible for the practical application of some new principle, and this is condemned as an unsatisfactory method of rewarding the research worker. Similar views are expressed in the recent report[1] of the Privy Council Committee for Scientific and Industrial Research. This Committee is "strongly of opinion that both the community and the original investigator would alike suffer if the seeker after new knowledge were encouraged to lay claim to a share in the profits that may accrue from the subsequent applications by other workers of purely scientific discoveries to productive ends." Against these negative views both reports are strongly in favour of securing adequate means of livelihood to the man of science. This does not only mean that salaries should be of a sufficiently high standard to enable the research worker to live; he should be able to live comfortably and enjoy the leisure and independence enjoyed by others of the same rank and class, whose services to the community can never be in the aggregate so great.

This brings us back to the financial support of research. In the direct method of financial encouragement the worker may be either full-time or part-time. The former is held to be desirable for the young worker and post-graduate student, and the report of the National Union of Scientific Workers urges that such work should always be undertaken in connexion with a university. While this recommendation raises several difficult problems, the principle seems to be generally accepted. Part-time research work presents several different points of view. Most university professorships are really part-time research posts, but in some cases it is to be regretted that the time allowed for research is insufficient. On the other hand, at the lower end of the scale many junior university appointments are so inadequately paid that students with the ability to undertake research are attracted elsewhere. Funds for the encouragement of research could admirably be devoted to the retaining of keen young minds. Then come the questions of grants for apparatus and for publication. While the offer of out-of-pocket expenses at the present time often produces results out of proportion to the sums expended, it is recommended that research workers should receive salaries large enough to enable them to provide their own material. Publication is undoubtedly a stimulus to research, and while grants in aid of this are very commonly made it is also desirable that the present overlapping of many societies and publications should be eliminated. The research worker has certain obligations to the community, but at the same time the community has many obligations to the research worker, and the claim of these workers is reasonable that they should be given adequate reward, so that they may pursue their investigations without financial worry and untempted by speculative prizes.

STIFF AND PAINFUL JOINTS.

CHRONIC arthritis, under which name we include all the conditions which used to be called rheumatic or poor man's gout, is a disease that is always with us, as it is has always been with our forefathers for hundreds, nay, thousands of years. Bones showing some of its unmistakable effects have been found in ancient Egyptian graves and cases of it seem to have occurred in almost every land and in most climates. The gout, which in the main is caused by over-indulgence in the pleasures of the table and of the bowl, becomes rarer year by year and bids fair to become only a pathological curiosity, but those forms of chronic arthritis which as far as we know are due to no excessive indulgences on the part of their victims, show no signs of departing from among us. The agricultural labourer has too often been rewarded for a manhood of frugal fare and hard labour in all weathers by an old age of crippled limbs and bowed back. The poor seamstress who has probably lived chiefly upon bread and tea has her hands so crippled as to preclude her earning any longer her scanty livelihood. Familiarity has bred not contempt for such sufferings but a certain degree of indifference, as compared with the interest and alarm with which we regard an epidemic of encephalitis or cerebro-spinal fever. We therefore welcome the address of Mr. JAMES R. KERR, which is printed in this issue and which very usefully draws attention to the important part that may be played by orthopædic treatment of chronic joint troubles. Much time has been spent in an attempt to classify the various forms of what used to be called rheumatic gout, but from the point of view of treatment it matters little whether with A. PRIBRAM we recognise 21 varieties or only two with R. JONES and R. W. LOVETT and others. The recognition of the existence of a proliferative and a degenerative type is of practical value, for the former is far less amenable to orthopædic treatment than is the latter, which, however, causes such a huge amount of suffering and disability to the middle-aged and aged of both sexes.

Pathologists have for many years been trying to find the cause or causes of this group of affections, but although various micro-organisms have been accused, no unanimous verdict has convicted any of them. It is true that the connexion with joint troubles of various septic foci—especially in the alimentary tract from the lips to the anus—has been practically established, and some striking cures have followed the removal of such foci, but there remains a vast mass of cases in which no such connexion can be established and no such cures claimed. Because complete cure can seldom if ever be hoped for, it has been too much the custom to regard these unhappy sufferers as beyond the reach of surgical help. When old BENGY, in "Tom Brown's Schooldays," asked the wise man for a cure for his lumbago, he was told that churchyard mould was the only thing that would cure "th' rhumatis," and this discouraging prognosis is still made with more or less circumlocution in only too many cases. The figures quoted by Mr. KERR from the report of the Ministry of Health make evident the vast importance of such diseases as arthritis deformans to the industrial population of this country, and arouse our pity for the terrible aggregate of suffering which accompanies them. Because cure is seldom probable, contemplation of them should not induce despair; should arouse a determination to use all the possible means of alleviation, and especially those orthopædic measures which offer the most hope. In many cases pain may be relieved and mobility restored or improved by operation on the affected joints. In others, and particularly when, for instance, only one hip-joint is affected, an arthrodesis may restore painless active movement to the body as a whole, although, paradoxically, it abolishes it in one important joint. More generally, correction of deformity, support by means of splints and instruments, and massage and physiotherapeusis directed to the restoration of movement and the redevelopment of atrophied muscles, play the most important parts in relieving disability.

It is one thing to awaken a consciousness of the value of active treatment of chronic arthritis in the profession generally. It is far more difficult to point out by what organisations such treatment can be made to reach the numerous cases which require it throughout the country. Great efforts have been, and are being, made to provide for the care and cure of crippled children by founding a network of hospitals and clinics all over the country, based on the model of the Baschurch (Shropshire) organisation. As yet the Central Committee for the Care of Cripples has probably had its hands full enough in watching over the interests of children, but there seems to be no reason why in time the benefits of the cripples' hospitals and clinics should not be extended to those adults who are so unlucky as to suffer from arthritis deformans. General practitioners throughout the country must be looked to for advice as to how early and appropriate treatment can be given to their crippled patients. At present no one can blame them if they refrain from tantalising the sufferers with hopes of relief, when they know that owing to the lack of adequate accommodation the necessary treatment is beyond their reach. There is, however, one class of cases which needs for its treatment no open operation, no elaborate or costly appliance, but which can be treated as well by the practitioner with the ordinary resources of medical practice as by a specialist in an elaborately equipped hospital. We refer to that form of arthritis which affects the wrists and the joints of the fingers, and of which the result is too often most disabling in that it interferes with wage-earning to a disastrous extent. The earliest possible constitutional and orthopædic treatment is desirable for such cases, which are most intractable if left untreated until gross changes have occurred.

◆

THE CONDUCT OF A G.M.C. ELECTION.

AT a meeting of the Branch Council of the General Medical Council for England, which took place during the recent session, a report was submitted by Mr. NORMAN KING, the Registrar, on the conduct of the election of Direct Representatives; the contest concerned England only, as the Scottish and Irish Representatives were returned unopposed. From the report we gather that excellent work must have been done by the staff in bringing the Register up to date, so that it should serve as a trustworthy electoral roll, in supervising the issue of the ballot papers, and, most importantly, in the scrutiny of results. We all know to what an extent during the last few years the entries in our personal address-books have had to be changed, so that it is not surprising to learn that when the outer covers of the voting papers were opened on their return, many of them contained changes of address for use in the future Register, as well as requests for the registration of additional qualifications and other matters which required attention. All this meant work for the staff that had to be done intelligently and promptly. Moreover, such a large shifting of residence implied the sending of duplicate forms, and the criticism of the Registrar's office, which appeared in certain daily papers, with regard to the late issue of some forms, was unintelligent. To those who had not notified a change of address voting papers could not be sent which should arrive at the earliest possible date, but the Registrar points out that some of the practitioners who wrote to say that they had received no voting papers made their complaint prior to the official date of issue.

It is an excellent thing that the medical constituency should keep the Registrar's office up to the mark, but it would be piquant to know whether some of the over-critical were among the considerable number of men who lost their votes by not attending to the clearly-printed instructions sent to them. The total number of voting papers issued for the English election was 29,179, of which only 607, or about 2 per cent., were returned as "dead letters," an occurrence which justifies any claim that the Registrar might like to make that no book of its kind is more accurate than the Medical Register. We have, then, to consider 28,572 circulars to which 15,229 replies were received—i.e., the percentage of the constituency which took part in the election was 55·26. But 562 out of these rendered their votes invalid by disregarding instructions, and that seems to us far too high a percentage of carelessness, considering the education of the voters. The cost of the election, which compares favourably with the cost on previous occasions, is worth attention, for it is not infrequently urged upon us that the quick and proper way of bringing certain things to the notice of all medical men is to issue a circular. Dealing with the English constituency alone the cost of the election was £373, not inclusive of the mass of extra work due to the necessity for conducting the operations between two specified and adjacent dates. For this extra work a modest grant was voted to those concerned, with the result that the total cost of the election can be roughly stated at £500. Those who think that a plebiscite of the medical profession ought to be undertaken in all circumstances where it would be convenient to ascertain corporate opinion would do well to consider the cost—as far as England only is concerned—and the probability of getting a substantial reply to any but the most vitally important sort of questionnaire.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The ninth meeting of the Commission was held at the Home Office on Dec. 4th, when the examination of the representatives of the Hearts of Oak Benefit Society, Mr. Hezekiah Dudley, chairman of the Executive Council, and Mr. J. P. Lewis, secretary, was continued. Various questions relating to transfers of membership, extension of medical benefit, to include specialist service and the desirability of adding dental benefit to the normal benefits of the Act were dealt with. Thereafter the examination of the representatives of the Ancient Order of Foresters—Mr. W. J. Torrance, High Chief Ranger, and Mr. Stanley Duff, secretary —was begun. The oral evidence given at the meeting of Nov. 20th, along with the statement submitted by the Hearts of Oak Benefit Society on which the latter part of that oral evidence was based, is on sale in proof form (3s.) at H.M. Stationery Office.

Annotations.

"Ne quid nimis."

POLIOMYELITIS.

DURING the last 20 years acute poliomyelitis has spread in epidemic form over the globe, and although small epidemics had occurred previous to 1905, it is only since that date that the disease has had its present wide prevalence. In 1912 poliomyelitis was recognised by the public health authorities in England as a definite specific fever and notification was adopted, although the British Isles suffered comparatively little during the epidemic periods. The disease, if not adequately treated, leaves a distressful train of disablement and crippling In 1916 the late Dr. F. E. Batten, when Lumleian lecturer to the Royal College of Physicians of London, discussed the condition, which was then obscure in many of its manifestations, and which had proved on occasion particularly dangerous to our troops (THE LANCET, 1916, i., 809, 829). There are many points in the disease which are still obscure, but in treatment it was recognised then, as now, that the most important factor was rest and prolonged after-care. At the present time treatment of this nature, which involves a protracted sojourn in hospital, is very difficult to obtain when the pressure on hospital accommodation is throughout the country so great. Particularly does this apply to London, and the attention of the Minister of Health has been drawn to the lack of facilities in London for dealing adequately with the after-effects of poliomyelitis in children. In ordinary circumstances the number of cases in any metropolitan borough is small, and would not justify a borough council in making independent provision for a form of treatment which is necessarily costly and elaborate, but the London County Council has started to organise arrangements under which hospital accommodation will be available for children during the later and chronic stages of the illness. The Ministry has therefore issued a circular (No. 338) to the metropolitan borough councils suggesting, as the best way of dealing with the problem, first that all practitioners residing in the area should be reminded of the importance of early diagnosis, and second that coöperation be aimed at with other authorities to send all children affected, whether the condition is slight or serious, to an institution equipped to give such special treatment as may be required to prevent avoidable muscular weakness and permanent deformity. Early diagnosis of poliomyelitis is not easy, and the significance of early symptoms may readily be overlooked. To assist medical practitioners in recognising these early symptoms the Ministry has prepared a memorandum, the substance of which we publish on p. 1250, which should prove of great value in ensuring notification before paralysis appears—the usual stage at which a diagnosis is made. If paralysis occurs, permanent crippling can only be avoided by prompt and long-continued orthopædic treatment. A case presenting the unusual feature of massive collapse of the lung is reported elsewhere (see p. 1222) by Dr. J. C. Regan, occurring in the Kingston Avenue Hospital, New York City.

CANCER OF THE ŒSOPHAGUS.

MALIGNANT growths of the œsophagus are, by reason of their situation in the middle of the thorax, perhaps more inaccessible to treatment than are cancers of any other part of the body where such tumours commonly occur. Surgical extirpation is practically impossible and, in the light of our present knowledge, the only methods which offer a prospect of cure are diathermy and radium. Owing largely to the difficulty of determining the extent of the burning when working at a long distance from the surface, and to the impossibility of estimating the thickness of the growth to be treated, diathermy is still an uncertain and dangerous method. It is doubtful if any complete cures have so far been obtained, but improvement in the permeability of the stricture has resulted; on the other hand, the resulting contraction of the fibrous tissue has been known to increase the stenosis, although apparently delaying the progress of the tumour, and fatal results have occurred from perforation into the mediastinum and pleural cavities. Nevertheless, when dealing with a fatal and otherwise incurable disease, dangerous methods are justifiable, if they can be shown to cure, or even to alleviate or delay the progress of, a proportion of cases. The application of radium can be more accurately limited, and is probably a safer method, though, with this remedy too, perforation has been known to occur.

In his Semon lecture, delivered at the Royal Society of Medicine last month, Dr. Jean Guisez did not mention diathermy, but he sounded a subdued note of hopefulness on the treatment of malignant growths of the œsophagus with radium, of which he has had a large experience in Paris. Before treatment is commenced it is necessary that the patient's general condition be good enough to allow of treatment, and that the neighbouring structures be not involved; this is determined as far as possible by skiagraphy, and a paralysed recurrent laryngeal nerve is generally considered as a contra-indication. The stenosis must also permit the passage of a No. 20 or 22 bougie, as this is equivalent to the size of the radium-bearing tube. Dr. Guisez holds that œsophagoscopy is absolutely necessary for diagnosis, and in all cases treated by radium he removes a portion of the growth for microscopical examination. The distance of the cancer from the teeth is accurately measured during the œsophagoscopy, and the radium is applied by means of two or three tubes fixed in file on a long sound. He employs a total of 100 to 120 mg. of radium bromide with thick screens of 1·5 mm. of platinum, so as to allow passage only of the gamma rays, and he gives five or six applications of 12 hours each, administered every other day. During the last 15 years he has treated 270 cases of cancer of the œsophagus by radium applications. In 30 cases the patients have survived for over 18 months, and four have died from other causes; the growth has not reappeared in two cases for 11 and 10 years respectively, in one case for five years, in four for four and three years, and in 12 cases for 18 months. The disappearance of the tumours is watched through the œsophagoscope. Dr. Guisez states that generally no trace is left, referring presumably to those cases just mentioned, and he also finds that his later results are better than the earlier ones. Disappearance, more or less complete, of the growth has thus been found to take place in 19 cases out of a total of 270—that is, in approximately 7 per cent., and a varying degree of palliation has been obtained in a further 30 cases, thus giving some improvement in about 18 per cent. of patients found suitable for this method.

As a large number of cases of œsophageal cancer are unsuitable for treatment by radium, by reason of the tightness of the stricture, the invasion of neighbouring structures, or bad condition of general health, the total results fall far short of these figures; but when we consider the great difficulties inherent in the treatment of tumours of this region, a certain degree of encouragement must be found in Dr. Guisez's thorough and careful work. Until recently any curative treatment of this disease was beyond the range of practical endeavour.

IMPROVED HEALTH CONDITIONS OF MAURITIUS.

WHEN, in 1921, Dr. Andrew Balfour made an adverse report on sanitary conditions in Mauritius it will be remembered[1] that between 3000 and 4000 persons in the island were falling victims to endemic malaria every year. Again, the death-rate of children under 5 in 1918 was over 300 per 1000 births. Dysentery and enteric fever were rife throughout the island, spread doubtless through surface contamination of the shallow wells which formed the water-supply of many parts. Dr. Balfour found no difficulty in accounting for the shocking vital statistics. He was dismayed by sights, smells, and noises which showed that not even the most elementary precautions were being taken in the interest of the public health. Flies infested the market-places; dogs had free run of the garbage and refuse heaps; pigs wallowed in the open sewage pits; and rats ran unmolested from ships moored at the quay-side of Port Louis on to the shore. The inadequacy of the medical and sanitary staff, who had, moreover, insufficient authority and power of administration, was, in Dr. Balfour's opinion, mainly responsible for the delay in carrying out urgently needed reforms.

A minute of a report submitted to the Colonial Secretary in January, 1924, by the late Governor, Sir Hesketh Bell, whose serious complaints of the sanitary conditions had induced the Colonial Office to send Dr. Balfour to Mauritius, shows that considerable progress has been made during the last three years. It will be remembered that a levy of £1,000,000 on the sugar industry provided the funds necessary for reclaiming and canalising land, and reforming the water-supply and drainage systems. The prohibition of the use of human fæcal material as manure on the fields, a vigorous anti-malaria campaign, and the provision of model dwellings for the working-classes have been among the reforms inaugurated. Strenuous efforts to improve the sanitation of Port Louis may be said to have begun in earnest in September, 1921. All authority over services affecting health was withdrawn from the municipality about that time, and the care of the streets, water-supplies, and sanitary services generally was confided to the sanitary branch of the medical department. To the energy and enthusiasm of Dr. T. B. Gilchrist and of his staff and subsequently to the good work done by Dr. Balfour Kirk, Sir Hesketh Bell attributes the reduction in the mortality at Port Louis from 2703 in 1921 to 1738 in 1923, out of a population of about 50,000, to mention only one of the signs of better conditions. The efficacy of the anti-malaria measures taken in the capital is indicated by diminution in the numbers of deaths from this cause from 333 in 1921 to 169 in 1923. It is of interest in the Mauritius medical report for the year ending December, 1923, to note that the death-rate for the whole colony (28·5 per 1000) is the lowest since 1891, and for Port Louis the rate (34·1 per 1000) is the lowest since 1880 (33·5 per 1000). It will be seen that under Sir Hesketh Bell's administration a quite promising start was made, and his successor, coming direct from the Colonial Office, will be able to carry on and extend the good work with full appreciation of the ideals to be attained.

CHRONAXIE.

AN account of his researches on the chronaxie of muscle and nerve in man, in health and disease, has just been published in the form of a monograph[1] by Dr. Georges Bourguignon. The chronaxie is determined by stimulating the muscle or nerve with measured galvanic currents, and attention is paid, not to the presence or absence of contraction of the muscle or the type or strength of contraction, but to the strength and duration of the current which produces the minimal response of the excited tissue. It has been shown during recent years that the stimulating power of the galvanic current depends not only on the strength of the current but also on its duration. Within certain limits a weak current flowing for a long time has the same power as a strong current flowing for a short time. When the current duration is progressively lengthened the current strength can be progressively weakened until a certain limit is reached at which further weakening of the current will not produce a response however long its duration. The minimum strength of current which produces the minimal response when the current flows for a so-called infinite duration is known as the rheobase. The rheobase differs in different muscles and even in the same muscle at different times, its value depending not only on the condition of the muscle, but also on its depth below the surface and the condition of the overlying skin and the position of the testing electrode. It gives no information of clinical value, but it must be determined before the chronaxie can be measured. To measure the chronaxie, say, of a muscle, the testing electrode is placed on the motor point and the rheobase is found. Then, without moving the electrode, the current representing the rheobase is doubled. The muscle, therefore, gives a stronger contraction. The duration of the current is now progressively diminished until a minimal contraction is once more obtained. The duration of the current which produces the minimal response when the rheobase is doubled is called the chronaxie. The value of knowing the chronaxie lies in the fact that the current is measured and that disturbing factors arising from the conditions of the test are eliminated. Currents of measured duration are applied when condensers are used for testing, but if the strength of the current is kept at a fixed value (as was the case in the methods hitherto used) the results are fallacious because the complications arising from the variability of the rheobase are not avoided. Dr. Bourguignon makes use of condensers of different capacity in order to obtain currents of different duration, and he finds this method more serviceable than that in which a special instrument, known as a chronaximeter, is used. But he takes the precaution of determining the rheobase before using the condensers. The chronaxie of normal muscle in man is very short, from 0·00016 to 0·0008 sec., and that of flexors is shorter than that of extensors. In muscles showing the reaction of degeneration the chronaxie is lengthened from 30 to 100 times. Dr. Bourguignon has studied the change of the chronaxie of muscle during degeneration and regeneration of the nerve, and has noted the evolution of its lengthening and subsequent shortening. His work is based on the researches of Lapicque. That part of it which deals with the human subject in health will be of interest to the physiologist. With regard to paralysed muscle, it is likely that the determination of the chronaxie will give more accurate information regarding diagnosis than can be obtained by testing the electrical reactions by the customary method. It remains to be seen whether information of clinical value regarding the progress and prognosis of a case can be obtained by study of the changes in the chronaxie.

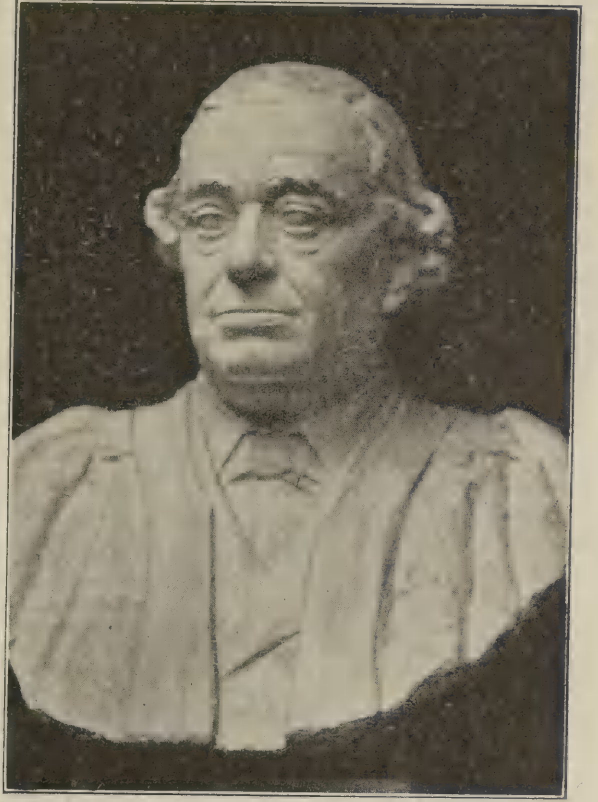
BLOOD REACTIONS IN ANÆSTHESIA.

IN the October number of the *British Journal of Anæsthesia* is a long paper on Blood Reactions in Anæsthesia, by C. D. Teake, assistant professor of pharmacology in the University of Wisconsin. The general opinion that during anæsthesia there is reduced alkalinity of the blood is confirmed, but Haldane's explanation of this as a result of acapnia is refuted. The conclusion arrived at as regards ether anæsthesia is that the immediate and marked fall in bicarbonate is independent of respiratory variations under the influence of ether, and is not caused by the formation of ketone bodies nor by lactic acid. There may be a ketosis developing several hours after withdrawal of the ether, due probably to deranged carbohydrate metabolism, which is apparently related to the depressing effect of ether on the normal insulin secretion of the pancreas. The interesting practical observation is made that the administration of insulin quickly and effectively clears up post-operative acidosis. Anoxæmia as a factor influencing the acid-base equilibrium can be excluded from ordinary ether and chloroform anæsthesia, but is most important in nitrous oxide and oxygen or ethylene-oxygen anæsthesia. There is always some reduced oxygen saturation of the arterial blood in nitrous oxide-oxygen anæsthesia. The suggestion is put forward, owing to experimental evidence recently obtained by the writer, that the cause of acidosis in ether anæsthesia is related to phosphorus metabolism.

THE LATE THOMAS RICHARD JESSOP.

Lady Moynihan, wife of Sir Berkeley Moynihan, recently unveiled a bust of her father, the late Mr. Thomas Richard Jessop, F.R.C.S., which has been presented to the Leeds General Infirmary by his widow, Mrs. Jessop. The name of Thomas Richard Jessop will long be remembered in Yorkshire, for he was for 33 years, from 1870, a member of the infirmary staff, and was a distinguished link in the long chain of able men who have built up a great tradition of surgery at Leeds. The bust is a strong and dignified piece of work in marble from the hands of Mrs. Quirk. Jessop of Leeds had a career of unbroken professional success. The surgeons of his day were resourceful, self-reliant, courageous, and untiring, for their work ranged generally over their science and art, while Jessop was typical of even an earlier race, for while he was the best operator in Leeds he remained in general practice. Born at Brighouse, educated at Giggleswick and Leeds, Jessop was a true Yorkshire product. After apprenticeship at Brighouse he became a pupil of the well-known Nunnerly of Leeds, and immediately upon qualification became house surgeon to the Leeds General Infirmary. From this post he went as surgeon to the Leeds Public Dispensary, while in connexion with the School of Medicine he was appointed lecturer on practical surgery. When that school was amalgamated with Yorkshire College he became a professor, but throughout the whole course of his professional career he



THOMAS RICHARD JESSOP.

accepted consulting work in medical, surgical, and gynæcological cases without distinction. He was to the end, and so styled himself, "a general consultant." For a long period he was on the Council of the Royal College of Surgeons of England, being senior Vice-President in 1901, in which year he delivered, as the Bradshaw lecturer of the College, a record of his own operative treatment of renal calculus. He was a strong personality, robust in thought, and decided in action, but full of kindliness, and all who knew him admired him for his great gifts. This journal was often beholden to him.

CHRONIC HEPATITIS.

APART from pigmentary disturbances (jaundice) or massive disturbances of conformation, which are usually the result either of acute or of very advanced disease, derangement of the liver produces signs and symptoms of such obscurity that progress in the early diagnosis of hepatic disease is slow. Evidence continues to accumulate, however, which tends to show that inflammatory changes in the liver occur with much greater frequency than has been suspected. This evidence is derived partly from experimental studies in animals, but more especially from the examination of sections of liver tissue removed during operations on the abdominal viscera. We have recently received an interesting reprint of the third series of Beaumont Lectures,[1] which summarises very clearly our present knowledge concerning these pathological processes. The book is in two main sections. Part 1, by Dr. C. G. Heyd and Dr. J. A. Killian, professors of surgery and of biochemistry at the New York Post-Graduate Medical School, deals with the clinical pathology and physiological chemistry of the liver in especial relation to chronic disease of the appendix and gall-bladder. Dr. Heyd calls attention to certain complications occasionally arising after operations on the gall-bladder which are not explicable as due to hæmorrhage, shock, embolism, or peritonitis. He recognises three more or less distinct groups. The first consists of obese subjects, who, after a comparatively simple operation on the gall-bladder, remain in a semi-unconscious condition, and, after a short period of delirium, sink into coma. Examination of the blood and cerebro-spinal fluid of these cases shows no evidence of renal defect nor of cerebral poisoning, and the suggestion is that the state of coma is due to an alkalosis associated with a marked increase in the carbon-dioxide combining power of the blood plasma. The second group includes many patients who have been the subject of long-standing gall-bladder infections, often with previous operations. After two days of satisfactory progress following their operation they become irritable and pass into a state of vaso-motor collapse with cold and sweating extremities. From this state they have often been restored by intravenous glucose administration. Dr. Heyd believes that this complication is due to some pancreatic toxin acting upon a liver whose protective function is temporarily in abeyance. The third group consists of cases with obstructive jaundice in whom operation has relieved the obstruction; at a period of about one week after the operation, at a time when all has appeared well and the jaundice has been diminishing, they have suddenly passed into coma and died, with no evidence either during life or after death of this coma being due to renal deficiency or any of the classical causes of this complication. These cases are believed to be due to the effect of a very slight toxæmia of infective origin acting upon a liver whose function has been materially deranged by long-standing disease. Dr. Killian, in an extensive series of observations has at present been able to discover little tangible biochemical evidence of such disorders of the liver. His studies of the blood-cholesterol, for example, have revealed no excess of this substance in cases of gall-stones unless either pregnancy or obstructive jaundice were present. The nitrogenous constituents of the blood were analysed in another series of cases with hepatic disease, but beyond a suggestive rise in the non-protein nitrogen fraction, nothing of importance was observed. He does, however, lay stress on one laboratory test before operations on the biliary tract—this is the estimation of the alkali reserve of the blood. In some cases the carbon-dioxide combining power of the plasma before operation has been found to be as high as 80 volumes per cent.; in these the post-operative administration of alkalis is strongly contra-indicated and may, indeed, prove disastrous if carried out. The last section of the book deals with the structural changes in the appendix, gall-bladder, and liver of 24 patients of various ages who had been operated on mainly for appendicular inflammation. The evidence of chronic hepatitis in these cases is unmistakable. Peribiliary or interstitial fibrosis in early or late stages was obvious in nearly every case. Inflammation of the gall-bladder was present to some extent in the great majority of cases, though not in sufficient degree to necessitate surgical interference. Prof. W. J. MacNeal, who is responsible for this section, is of opinion that the hepatic inflammation represents the normal physiological protective function of that organ in response to sepsis in the portal region. As to the cholecystitis, he believes that this is the result of infection by the lymphatic system from the liver, though the possibility of direct infection from the bile which is excreting the organisms from the liver remains a second possible cause.

SYPHILIS AND PERMISSION TO MARRY.

THE problem indicated by this heading has long been with us, but new side issues have recently developed in connexion with the latest advances in the diagnosis and treatment of syphilis. We also know much more about the prognosis, the chances of marital infection in the various stages of syphilis, than did an earlier generation. It is interesting for a moment to hark back to the conditions which A. Fournier, a representative of an older generation, considered necessary for a medical man to insist on when consulted about the prospective marriage of a syphilitic. He stipulated for the absence of recent manifestations, an advanced stage of the disease without signs of activity, a considerable interval since the last appearance of symptoms and adequate specific treatment. The modern criteria by which a syphilitic should be judged fit to enter into the bonds of matrimony have recently been discussed by Dr. Marcel Pinard, of Paris, in *Bruxelles Médical* for Oct. 5th. He insists that when syphilis is recent or neglected, marriage almost inevitably entails infection of one partner by the other. When the infection is of old standing, he finds that the chances of one partner infecting the other depend largely on the sex of the partner first infected. If it is the woman who is suffering from tertiary syphilis at the time of marriage she is not likely to infect her husband. But if it is the man who is suffering from syphilis in the tertiary stage at the time of marriage, he will very likely infect his wife through his semen, the uterus, Fallopian tubes, or peritoneum being the site of the primary infection which escapes detection. In such a case the woman's blood may give a positive Wassermann reaction, and, with little or no evidence of primary and secondary lesions, she may develop tertiary manifestations and suffer from aortitis and high arterial blood pressure, as well as passing the disease on to her progeny. Having commented on these more or less general rules with regard to the sex differences of syphilitic infection, Dr. Pinard proceeds to defend the practice, which he has followed since 1918, of giving his consent to marriage only when the employment of every modern diagnostic device has failed to show any sign of the disease. There must be no clinical or serological evidence of syphilis, an examination of the cerebro-spinal fluid must be negative, there must be a negative serological reaction after arsenical reactivation, there must be an interval of a year of absolute latency of the disease since treatment was given for primary syphilis, and this interval must be one of two years if specific treatment was instituted at a later stage. Dr. Pinard has never found this high standard fail him, though he admits that keeping to it may not provide an absolute guarantee that infection will not occur. He is not in favour of relaxing this standard, but if the prospective bride or bridegroom refuses to wait till all these conditions have been fulfilled, he suggests that, as the next best course, the medical examiner should urge the patient to be perfectly candid with his or her prospective partner, so that steps may be taken to continue the cure of the one partner, and prevent the infection of the other. In parts of Scandinavia medical examinations of candidates for marriage have become compulsory, and while Dr. Pinard does not plead for legislation in France in this manner, he considers it desirable that such medical examinations should be a matter of routine, of general custom. He relates many instructive incidents connected with his work as medical examiner of persons about to wed, and one of his points is that it pays the betrothed to be candid with each other before matrimony. We ought not to be surprised by the account given by Dr. Pinard of a man, who confided his secret to his fiancée, a lady belonging to a good provincial family. Her reply was: "Syphilis is no obstacle; I know what it is, father has it." But candour on one side met by ignorance on the other may spell disaster.

THE TREATMENT OF FEMORAL HERNIA.

IT is only of recent years that careful follow-up methods have enabled us to arrive at a true estimate of the success of operations for hernia. The optimistic outlook which prevailed received a rude shock during the war, when with many inexperienced operators at work the proportion of recurrences certainly reached a high figure. But that all these relapses were not due to lack of skill in the operators, but were to some extent inherent in the procedures in vogue, seems to be proved by the study of series of cases done in large clinics where the technique employed is certainly not below that standard which is expected from a well-trained experienced surgeon. If such groups of cases are followed up, there is a percentage of recurrence varying from 7 to 10 in inguinal hernia operations upon adults. These results bid fair to be improved upon, as the knowledge of the factors which tend to cause recurrence becomes more widespread. There has been for long a general impression that failure to cure is more likely with a femoral than an inguinal hernia, the belief being held that the rigid margins of the crural ring are more difficult to approximate and keep in apposition. This does not appear actually to be the case, for L. F. Watson[1] finds that recurrence after the operation from below amounts approximately to 4 per cent. in 469 cases. It is now becoming very general in a number of clinics to operate upon femoral hernia by the inguinal route. To T. Annandale must be given the credit for first deliberately attacking the hernia in this way in 1876,[2] but an Italian surgeon, G. Ruggi, in 1892, and G. Lothiessen, in 1898, exploited and popularised the inguinal method. This operation has certain advantages. The neck of the sac is thereby approached higher up and closure of the crural canal from above would seem to be more sure and easy. Nevertheless the figures given by Watson reveal a greater liability to recurrence after the inguinal than after the femoral operation, 4·8 per cent., compared with 4 per cent. Elsewhere in this issue Mr. F. Harvey relates his experience with the operation devised by Roux in 1899, in which the pubic attachment of Poupart's ligament is extended outwards by means of a metal staple. Of 46 cases traced by Mr. Harvey, recurrence only occurred once, giving a rate of just over 2 per cent. This is a strikingly good result and deserves attention as the method is a simple one. It might be thought that there would be objections to leaving a metal staple permanently embedded in the pubes, but it does not seem to lead to any trouble. E. Hey Groves[3] described another method for shifting outwards the inner attachment of Poupart's ligament without tension. His results were equally remarkable, 23 traced cases without a recurrence, of whom three had gone through a pregnancy subsequent to the operation. It would seem that the time has come to review the question of the operative treatment of femoral hernia and particularly to assign the inguinal operation its proper place. It is so attractively conceived and so efficiently designed for achieving its purpose, that surgeons will not feel inclined to abandon it until an investigation of the cases on which the statistics are based has been carried out, or the publication of further statistics confirms the above-recorded results.

THE LATE DR. ALEXANDER LEWERS.

NO words could have been more appropriate for the memorial tablet in the entrance hall of St. Vincent's Hospital, Melbourne, in memory of the late Dr. Alexander Lewers than those which, taken from Dr. Lewers's own writings, have been engraved on a simple brass tablet: "However Untimely the Fate of These and Such as These, Their Effort is Not Vain." Nor could the place have been more fitting, for a large part of the most active portion of his life was associated with the St. Vincent's Hospital, where, as the memorial states, he was senior physician from 1908 to 1922, and where he filled every position of honour, as clinical teacher and lecturer, chairman of the staff, and dean of the clinical school. To his wisdom the hospital owes much. Dr. Lewers received his early medical education at St. Mary's Hospital, London, and was for a time medical officer at Adelaide Hospital. After a post-graduate visit to England, during which he studied dermatology under the late Sir James Galloway and obtained a Diploma in Public Health, he returned to Australia and treated the first case of bubonic plague at the quarantine station at Coode Island. Dr. Lewers, to whose merits we were able to bear testimony at the time of his death some 15 months ago, was editor of the *Australian Medical Journal* for several years and was the Australian correspondent of THE LANCET.

CROWN GALLS.

THE cancer problem, and the problem of neoplastic growths in general with which it is inseparably linked up, has far wider bearings than its pressing relationship to human pathology, and neither the general reader nor the research worker can afford to neglect kindred conditions in animals and in the vegetable kingdom. One of the most interesting phenomena of this nature in the latter is that of the "crown gall." These tumour-like formations upon plants have been largely studied in America and especially carefully described by Erwin F. Smith.[4] It would appear that their bacterial origin is incontestable. From the large nodosities which go by this name, and whose most common site is at the junction of root and stem in plants, an organism may be regularly isolated to which the name of *Bacterium tumefaciens* has been given. This is a small, Gram-negative, motile bacillus which, on inoculation in pure culture, has the effect of reproducing tumour-like masses in a number of vegetable species which are indistinguishable from those appearing spontaneously. The work of investigating these growths has been recently taken up in France by J. Magrow,[5] who has in many directions confirmed the observations previously published in Copenhagen, Prague, and America. By means of a culture of *B. tumefaciens* derived from the stocks of the

[5] J. Magrow: Recherches expérimentales sur le cancer des plantes, Annales de l'Institut Pasteur, October, 1924.

Pasteur Institute, tumours have been produced in a large proportion of the plants experimented upon, their localisation being either at the junction of root and stem, at the base of a leaf, or in the leaf stalk, according to where the inoculation was made. A considerable variety of plants is susceptible. The growths, which are made up of small imperfectly differentiated cells, are derived from those elements in the plant which are naturally endowed with marked proliferative ability, and the neoplasm when it is once inaugurated pursues a progressive course, infiltrating, compressing, and destroying the tissues, and finally producing in the plant a state of malnutrition or "cachexia." The chief point upon which Mr. Magrow has been unable to confirm other workers' observations is in regard to the occurrence of "metastatic" growths, but he notes that his strain of *B. tumefaciens* lacked pathogenicity for *Anthemis frutescens*, which is the most favourable plant for their observation. It would appear that the several strains of this organism which are in existence vary a good deal in their pathogenic ability. Although readily cultivable from the lesions, the organism cannot be demonstrated with certainty within the growth. This may be due to their being present in the tumours in very small numbers, or to technical difficulties in demonstrating them in vegetable tissues. The whole matter of these growths and their close simulation of malignant disease in man and animals is one of great interest in general pathology and deserves to be widely studied.

PSEUDOMYXOMA PERITONEI.

IN a paper read before the Chicago Gynecological Society, Dr. Emil Ries,[1] professor of gynæcology in the Post-Graduate Hospital and Medical School, Chicago, who reports two illustrative cases which came under his observation in the course of 16 years, states that pseudomyxoma peritonei is a secondary condition, due to escape of gelatinous material from a primary tumour arising in the ovaries, appendix, or both, or more rarely in other organs. The ovarian tumours are always pseudomucinous cystomata in their entirety or at least partially. The appendices from which pseudomyxoma peritonei starts are found to be more or less cystic, often show diverticula, and may contain papillomatous tumours. Previous attacks of appendicitis have been frequently noted in the cases which originated from the appendix alone. Some writers maintain that the pseudomyxoma peritonei originating in ruptured ovarian tumours is much more liable to continue even after careful operation and to cause death, while the pseudomyxoma following ruptured cyst of the appendix is less dangerous. Examples of recurrence and death, however, as well as cases of apparent cure by operation, have been recorded, whichever the original source of the pseudomyxoma may have been. Operative treatment consists in the removal of the original source and the treatment of the pseudomyxoma. Ovarian tumours should be removed whether they are ruptured or not, and since many of these tumours are more or less intraligamentary hysterectomy may also be required. The appendix should be removed whether it is much enlarged or not, whether or not it shows diverticula or forms a ruptured or closed cyst. When it is so firmly imbedded in the gelatinous material that it cannot be isolated, as in a case reported by Hartmann, resection of the cæcum may be required. The results of operation have been good, even though the entire gelatinous masses on the parietal and visceral peritoneum have not been removed. Repeated operations have been performed in a number of cases, and recoveries for longer or shorter periods have taken place. The longest reported time of cure is that of Dr. Ries's first patient, who was alive and well 17 years after an operation at the age of 55 for ruptured ovarian pseudomucinous cystoma, and ruptured cyst of the appendix with papilloma.

Obituary.

SIDNEY JOHNSON TAYLOR, M.D. EDIN., M.R.C.S. ENG.

BY the recent death at the age of 67 of Dr. S. Johnson Taylor, of Norwich, the medical profession has lost an experienced and skilful practitioner, who for a long time played a prominent part as an ophthalmic surgeon, not only in Norwich and the surrounding district in which he practised, but also in the various societies and congresses connected with ophthalmology.

Sidney Johnson Taylor received his medical education at St. Thomas's Hospital, London, and Edinburgh University, and also pursued the special study of diseases of the eye in Vienna. He took his M.R.C.S. in 1878, and his M.B. and C.M. Edin. in 1882, being co-equal in competition for the Ettles Scholarship. He also won the Musgrove Scholarship at St. Thomas's Hospital. In 1922 he obtained the M.D. Edin. He was for a time resident medical officer to the Severn Tunnel Hospital, and subsequently engaged in general practice at St. Servan, near Dinard, in Brittany. Deciding to take up ophthalmic surgery as his specialty, he returned to Edinburgh, worked under Argyll Robertson, and then obtained the post of clinical assistant to the Royal London Ophthalmic Hospital at Moorfields, where he profited from the teaching of Nettleship. Later he settled in Norwich, where his knowledge and skill in dealing with diseases, defects, and injuries of the eye secured him a well-merited reputation. He became a member of the Ophthalmological Society of the United Kingdom in 1889, and for 30 years was a regular attender at its meetings and the contributor of many valuable articles to its Transactions. He was thorough in his diagnostic investigations, well read in the literature of his specialty, and a skilful operator. His genial and considerate nature not only inspired the confidence of his patients, but secured their lasting friendship.

The death of his son, Charles Murchison Johnson Taylor, was his great grief in his later years, and to his memory, as also to that of his own old teacher, Charles Murchison, F.R.S., M.D., after whom the son was named, he last year presented Moorfields Hospital with the sum of £1000 for the endowment of a bed.

THE LATE DR. JOHN ROBSON.—John Robson, M.D., F.R.C.S. Edin., who died in his eighty-second year on Nov. 28th at Guildford, Surrey, where he had resided for some time, was well known in the Rock Ferry district, near Liverpool, where he carried on an extensive practice. He went to Rock Ferry over 40 years ago, and retired from active practice after 20 years' work there. About 30 years ago he lost his two daughters, who were drowned at Corwen.

THE LATE DR. G. D. COMPSTON.—George Dean Compston, M.R.C.S. Eng., of Halton, near Leeds, died on Dec. 2nd in London in his thirty-eighth year. He was the second son of Mr. J. A. Compston, K.C., the Recorder of Leeds. He had been ill for a considerable time and underwent an operation at Hastings last August. After taking his B.A. at Cambridge, he studied medicine at Cambridge and at Middlesex Hospital, becoming M.R.C.S. and L.R.C.P. in 1913. He acted as house surgeon in Middlesex Hospital, as assistant medical officer at the London Fever Hospital, and in Hastings, where he began practice, he held public medical appointments. Later, in Leeds, he served on the staff of the Leeds Women and Children's Hospital. When in practice in Hastings and during the war, Dr. Compston served with the R.A.M.C. with the rank of captain, and after service in Mesopotamia he suffered from severe dysentery. At Cambridge he was distinguished in rowing circles and was awarded a rowing "blue," being cox in the Cambridge boat in 1909. He married in 1914 and leaves a widow and two sons.

THE house and library of the Royal Society of Medicine will be closed from the evening of Tuesday, Dec. 23rd, until Monday morning, Dec. 29th.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

C.—TREATMENT OF TUBERCULOUS PERITONITIS.

TREATMENT in tuberculous peritonitis, as in other tuberculous lesions, tends to become more and more conservative. This follows the acceptance of the theory that in most cases of surgical tuberculosis the disease is a local manifestation of a general systemic infection. A. Rollier considers tuberculous peritonitis to be almost always consecutive to pulmonary, pleuro-pulmonary, or pleural lesions.[1] He is strongly opposed to operation in this disease, on the ground that it "may produce a locus minoris resistentiæ and a depression of general health which not infrequently results in renewed pulmonary activity." Unfortunately, the ideal is not always attainable; operations are performed from time to time either deliberately or accidentally—deliberately in order to evacuate fluid in the ascitic variety or to meet some emergency such as intestinal obstruction in the fibro-adhesive variety; accidentally, as the result of a mistaken diagnosis.

Tuberculous peritonitis requires a more exact classification. A wide distinction may be drawn between primary and secondary conditions. Among the primary can be included the miliary type with ascites and the fibrous adhesive type, which I look upon as a later stage of the ascitic following the absorption of the fluid, a stage of partial cure. These cases are systemic in origin. Among the secondary conditions peritonitis may follow tuberculous enteritis, or sometimes tuberculous salpingitis, ileo-cæcal tuberculosis (the entero-peritoneal type of Hartmann), and the large class of caseous tuberculosis which may be regarded as a late stage of mesenteric gland tuberculosis. It is doubtful whether these secondary infections are systemic at all; they may be looked on as local implantations of tubercle operating through the intestinal tract; especially is this probable in the case of mesenteric gland tuberculosis which is comparable with tuberculosis of the cervical glands. If this view is true it justifies operation in the secondary types, while limiting operation in the primary types to the relief of intestinal obstruction. It is true that cœliotomy has had many successes in the ascitic form, and it may still have its place where the modern conservative methods are not available.

Conservative Treatment of Uncomplicated Tuberculous Peritonitis.

The preliminary examination of cases of uncomplicated tuberculous peritonitis is on the same lines as for all abdominal conditions. A thorough investigation is necessary to exclude sepsis in the nasal passages (rhinitis or sinusitis), in the pharynx and nasopharynx (and this may necessitate the removal of adenoids or septic tonsils), and in the mouth (dental caries). The examination of the lungs is especially important and it is well to estimate the Wassermann reaction. The stools should be investigated for evidence of undigested food and occult blood.

When any septic foci have been removed or excluded, the patients are confined to bed, "simple recumbency" in Sir Henry Gauvain's phrase, or as Rollier suggests in the acute stages, "immobilisation in the dorsal position." The diet should be regulated to avoid all materials liable to irritate the intestine.

Graduated sun treatment as employed at Leysin is then used. This consists in a very gradual exposure to sunlight, the ultra-violet rays of which, while they have very little penetrative power, are strongly bactericidal and in addition appear to increase the power of the blood to destroy disease-producing organisms, at the same time increasing the calcium metabolism. Gauvain's instructions for this treatment are as follows:—

1st day .. .. Expose legs to knees for 5
2nd ,, ... ,, ,, ,, ,, ,, 10
3rd ,, ... ,, ,, ,, groins ,, 10
4th ,, .. Expose legs and buttocks for 20
} minutes hourly for three successive hours.
5th ,, In addition one aspect of the trunk for five minutes.
8th ,, Total exposure for 20 min. hourly for three successive hours.

The exposure is regulated by the amount of pigmentation, it being understood that patients who will not pigment or only freckle, require much more care than those that pigment well. Eventually a total exposure of two to three hours a day may be obtained, the greatest care being taken to protect the head and to prevent blistering. The coincident exposure to cold air increases metabolism, which is still further increased if sea-bathing is added. The very young, and aged and infirm patients, require special care. Rollier says that the sun treatment produces its best results in the ascitic type, but in the caseous type a congestive reaction accompanied by vomiting and fever may result. Gauvain says that uncomplicated cases almost invariably do well, that the fibrous adhesive type often obtains rapid and permanent benefit, and that such complications as intestinal obstruction are very rare at Alton.

X ray exposures may be employed in the absence of sunlight. The abdomen is divided into quadrants, only one being irradiated at a sitting with an interval of five to six days. This treatment is valuable in the fibrous adhesive type, but is of little benefit in acute forms.

Alternatively the *mercury-vapour lamp* may be employed, it being remembered that at a distance of one metre its ultra-violet intensity is over three times that of the sun. This is increased in a hot room and diminished in cold, and erythema is easily produced.

Tuberculin.—Opinions are divided as to the value of tuberculin. Rollier has almost abandoned it, but others use it, though not in acute cases. It is usual to start with a minimal dose, 1/10,000,000 mg., progressively doubled at five-day intervals, till 1 mg. is reached. This dose is then given at fortnightly intervals for a year. If there is no pyrexia the initial dose may be 1/10,000 mg., but it is important to take regular readings of the temperature in the rectum.

Operative Treatment.

Operative treatment of tuberculous peritonitis concerns itself mainly in dealing with complications, of which the most common is intestinal obstruction. From time to time one is called upon to treat the ascitic type, and surgical measures generally meet with immediate success. Operation must be accepted, however, merely as one step in the treatment; the aim is to evacuate a fluid of low bactericidal power in the hope that it will be replaced by a temporary serous effusion of a higher bactericidal power. The operation consists of a cœliotomy, the evacuation of the fluid, the removal of any local primary cause—e.g., appendix or Fallopian tube, and closure without drainage. All ligatures and sutures must be of catgut. In a short series of 17 consecutive cases operated upon by me for tuberculous peritonitis which I have collected for the purpose of illustrating this article, I include two ascitic cases. There were three other cases where miliary tubercles were found during the course of operations done for various reasons, in only one of which free fluid was found. All these five cases were in females and all did well. As to the fibrous and caseous types there were nine cases of intestinal obstruction, of which seven resulted from adhesions and two from intestinal ulceration. Of the seven adhesion obstructions, five occurred in females and all recovered in spite of the fact that intestinal resection was necessary in one case and a lateral anastomosis in another; two occurred in males and both died, one shortly after operation, the other in three weeks, and in both cases obstruction had been present for a long period. The two intestinal-ulceration obstructions were treated by resection, a male in whom obstruction had been present for six weeks dying, a female operated on for acute obstruction recovering. Operation in these fibrous or caseous cases, where obstruction is present, is very difficult. There is the risk of injuring adherent intestine in opening the abdomen, and the most gentle handling is needed in releasing adhesions in order to avoid tearing the gut, an accident which frequently leads to fistula and causes a high mortality. If, in addition, it is necessary to do a resection or a short circuit, the chance of a successful issue is still further reduced. They are operations of necessity and not of choice; they are not done in the hope of curing the peritonitis, but to relieve a complication, and their value must be judged from this standpoint.

---

[1] Heliotherapy. Oxford Medical Publications. 1923.

There are two other conditions which may give rise to tuberculous peritonitis secondarily. The first is

Tuberculous Disease of the Mesenteric Glands.

Three stages of development are recognised, a tuberculous enlargement, caseation, and calcification. It is in the stage of caseation that most of the complications arise, the serous covering becoming affected, leading to adhesions, and, if the gland burst, the abdomen may be flooded with caseous material, leading to localised abscesses, or diffuse peritonitis. This is the stage known as the caseous stage of tuberculous peritonitis, really a misnomer, for it is, I believe, a late stage in mesenteric gland tuberculosis, rather than a late stage in tuberculous peritonitis. These conditions are the despair of the surgeon who must, on occasion, operate for the relief of some urgent catastrophe, such as obstruction. Success lies in the early diagnosis of mesenteric gland tuberculosis and adequate treatment.

During the period covered by the series of 17 cases quoted above, I have operated upon 68 cases of mesenteric gland tuberculosis with a mortality of two, both late cases requiring resection. One of these died soon after the operation, the other a few weeks after of pulmonary phthisis. Three cases had intussusception and all did well. The operation consists of a laparotomy in the middle line below the umbilicus. The ileo-cæcal mesentery, a favourite site for these glands, is examined first and then the mesentery of the ileum, it being remembered that the most infected gland may be high up in the root of the mesentery. Attack is directed to the caseating glands, which are deliberately dissected out, the serous covering being preserved as far as possible. There is little, if any, risk of so damaging the mesentery that the viability of the intestinal coil is endangered, but the incision in the serosa must be sutured with the finest catgut after careful hæmostasis to prevent subsequent adhesions. The appendix is removed and the abdomen closed.

Ileo-cæcal Tuberculosis.

Ileo-cæcal tuberculosis in its entero-peritoneal form may also lead to tuberculous peritonitis. This variety is not well suited to operative measures, except in its early stages, and results do not compare with those obtained in the hyperplastic form. In the series of 17 cases there were three successful cases of ileo-cæcal tuberculosis, but in none was the peritoneum much affected. The treatment is a block resection of the cæcum with the lower six inches of the ileum.

H. W. Carson, F.R.C.S. Eng.,
Senior Surgeon, Prince of Wales's General Hospital, London.

Special Articles.

THE EARLY DIAGNOSIS OF ACUTE POLIOMYELITIS.

The early diagnosis of acute poliomyelitis by furnishing the indications for timely treatment is a strong factor in obviating the sequelæ of permanent crippling and disablement that too often follow the disease, but the first indications of poliomyelitis often pass unobserved as the condition is of comparatively infrequent incidence as compared to the commoner infections of childhood. As an aid, therefore, to early diagnosis, the Ministry of Health has issued a memorandum[1] for the use of medical practitioners which sets out, clearly and simply, the chief features of the epidemiology and early manifestations of the disease, as follows.

Features of the Disease and its Notification.

Acute poliomyelitis is an infectious disease which attacks the central nervous system and may give rise to paralysis. In this respect it is comparable with cerebro-spinal fever and encephalitis lethargica. The disease has long been known, under the name of "infantile paralysis," as a form of paralysis of which sporadic cases occur, chiefly in children and less frequently in adults. In recent years it has occurred in epidemic form in America, Australia, and in some parts of Europe. The New York epidemic of 1916 was on a scale of considerable magnitude. A number of local outbreaks have occurred in this country. Polio-encephalitis and poliomyelitis were made compulsorily notifiable in London as from March 13th, 1912.

Pathology.

The virus of the disease is so minute that it passes through the finest filter. It attacks the nervous system causing inflammation of the grey matter of the spinal cord, especially of its anterior cornua. In some cases the brain may be primarily or secondarily affected (polio-encephalo-myelitis). The meninges also may be implicated in the morbid process.

Epidemiology.

Poliomyelitis is most *prevalent* in the summer. It appears to have no special relationship to social or sanitary conditions and often occurs in sparsely-populated districts. Clinical evidence points to an *incubation* period in the disease of four or five days, though shorter and much longer incubation periods are recorded. The disease presents an erratic character as regards *infectivity;* this in part may be due to failure to recognise the mild and abortive cases. In some instances the disease has developed after contact of short duration with a patient suffering from poliomyelitis, and multiple attacks in households are not uncommon. In other instances children have been known to sleep in the same bed with a patient and to escape infection. The *fatality* of poliomyelitis varies within wide limits. Commonly 10 to 12 per cent. of the attacks prove fatal, but much depends on the proportion of mild or so-called abortive cases which are recognised. It is important to isolate all patients suffering from poliomyelitis in the acute stage, whether the manifestation of illness be slight or severe. Prompt action in this respect largely minimises the risk of spread of an epidemic.

Symptomatology.

The early manifestations of poliomyelitis give rise to considerable difficulty in diagnosis at a stage of the disease—namely, before paralysis supervenes, when its identification is of extreme importance. Usually an initial febrile attack occurs, the temperature seldom rising above 102°–103° F. This febrile period is of comparatively short duration, lasting for about two to five days and rarely longer than ten days. A curious hump in the temperature curve, "the dromedary temperature" of Draper, may be observed in some cases. Recrudescence of the fever usually indicates further progress of the disease and paralysis. Commonly there is malaise and drowsiness, sometimes intensified as stupor, accompanied by headaches and occasionally by vomiting; there is often nasal and pharyngeal catarrh or gastro-intestinal disturbance associated with loss of appetite, sickness, constipation, or diarrhœa. Profuse sweating is common; there in no characteristic skin eruption, but eruptions such as herpes zoster, herpes labialis, and erythema are sometimes recorded. The patient is irritable and restless as a rule, especially when roused from somnolence; he may be mentally confused or delirious. Twitchings and tremors are generally observed even in mild cases. Rigidity of the muscles of the neck and spine frequently occurs and the head may be retracted, there may be pain and tenderness of the skin, over the spine and on pressure of muscles and nerves. Retention of urine is common. Convulsions are sometimes met with in young children. Generally, if the patient is carefully watched, an irritative stage (usually indicated by transient nystagmus, twitchings, and paresis of limbs or of groups of muscles) can be recognised prior to the paralytic stage. At this time the knee-jerk may be exaggerated. Definite paralysis, usually of the flaccid type, may follow primary symptoms; it affects one or more groups of muscles, especially of the limbs, but may involve any part of the muscular system. The reflexes are now commonly absent.

---

[1] Note on the Early Diagnosis of Acute Poliomyelitis. London: H.M. Stationery Office. 1*d*.

Diagnosis.

In some cases the sudden onset of paralysis is apparent, but in the majority the serious nature of the illness at the outset may be obscure. On the other hand, the implication of the medulla, brain, meninges, or special nerves may give rise to additional symptoms, causing possible confusion: thus in bulbar paralysis speech disturbances are noted. In these anomalous cases confusion in the differential diagnosis between poliomyelitis and encephalitis lethargica or cerebro-spinal fever is apt to occur; the latter error is more frequent when the meninges are affected. The meningeal type may also be confused with tuberculous meningitis or septic meningitis. In such cases, the previous medical history of the patient and the presence of other similar cases in the vicinity, together with examination of the cerebro-spinal fluid, may aid the diagnosis. The symptoms of poliomyelitis before the onset of paralysis have frequently been attributed to influenza. Cases at this stage have also been diagnosed as sunstroke, enteric fever, food poisoning, rheumatic fever, and a number of other diseases. In the mild or abortive cases of poliomyelitis in which no paralysis supervenes the symptoms are similar to those ushering in the graver forms. They are often associated with general or localised muscular weakness or gastro-intestinal disturbance. Such symptoms, if they occur in patients having association with paralytic cases, should arouse suspicion.

Fatality and After-effects.

Death in the acute stage of the illness is usually due to bronchitis or broncho-pneumonia, which supervenes through affection of the respiratory centres. Those who recover are liable to permanent paralysis of particular groups of muscles, and it has been asserted that over half the patients who survive an attack of acute poliomyelitis remain crippled to a greater or less extent throughout life.

The London County Council has for some years past made available for medical practitioners the services of one or other of its medical officers in a consultative capacity in suspected cases of cerebro-spinal fever polio-encephalitis, poliomyelitis, and encephalitis lethargica. When necessary a lumbar puncture has been performed and an examination of the fluid made. It is understood that the services of Dr. J. A. H. Brincker and Dr. J. Graham Forbes are available for this purpose and can be obtained on application to the Public Health Department, County Hall, London, S.E. (Tel.: Hop 5000).

INFECTIOUS DISEASES ABROAD.

Outbreak in Japan of a Disease Resembling Encephalitis Lethargica.

IN Japan a serious epidemic has been described of an affection of the central nervous system, which was first reported unofficially as cerebro-spinal fever, later as encephalitis lethargica, later as a hitherto unidentified disease. The first cases occurred in July in the Department of Toyama on the west coast of the principal island. During August the provinces bordering on the inland sea became severely affected, and during September the disease spread over nearly the whole of Japan. The cases officially reported between August 12th and Sept. 29th numbered 6551 and the case-mortality was stated to be 54·8 per cent. In the provinces most affected the onset of the outbreak was sudden and the curve of cases reached its maximum in the last week of August or the first week of September, thereafter declining rapidly. Of 299 cases notified in the Department of Tokushima 185 were among men, 114 among women, and 62 per cent. of the cases were in persons over 50 years of age. Instances in which more than two cases occurred in the same family were rare. A description of the clinical features of the disease forwarded by the Japanese Health Service to the Health Section of the League of Nations,[1] states that the symptoms of the disease resembled those of encephalitis lethargica, but that the usual eye symptoms were absent. The onset was sudden with high temperature; after one or two days there was loss of consciousness and delirium. Death occurred in from five to ten days, or recovery took place with a fall of temperature and return to consciousness. The cerebro-spinal fluid was clear in all cases examined and no pathogenic organism was found. The incubation period in man was indefinite; in animal experiments it was found to be about three days.

Pneumonic Plague in Los Angeles, California.

A somewhat severe outbreak of pneumonic plague, which was at first diagnosed as "malignant pneumonia," recently occurred in this city. The first death occurred on Oct. 19th, and between that date and Nov. 11th there were 38 cases with 31 deaths, all the cases except four being of the pneumonic type. The area affected is limited to a small portion occupied by aliens in the Mexican quarter of the city; a sanitary cordon has been drawn round it and vigorous measures of inspection, fumigation, and rat destruction are in progress under the supervision of officers of the United States Public Health Service. It is reported that the situation is well in hand, and that there is little reason to fear the development of a widespread epidemic.

MEDICINE AND THE LAW.

VALID CERTIFICATES: A MISUNDERSTANDING CLEARED UP.

AN interpretation of the law, mainly of course for the use of foreign countries, has come before the General Medical Council. A paragraph in the Supplement to the *British Medical Journal* of Oct. 4th stated that instructions had been received from the immigration authorities of the United States that in future persons desiring to emigrate from this country to the United States must be examined by medical practitioners who are members of the British Medical Association. This statement naturally provoked some interest among the members of the medical profession who are not members of the Association, and it was brought to the notice of the General Medical Council.

---

[1] Reported in the Monthly Epidemiological Report of the Health Section of the League of Nations, No. 72, Nov. 15th, 1924, p. 673.

A letter was written accordingly to the American Consul, pointing out that the instruction appeared to have been given under a misapprehension, for the only persons legally qualified in the United Kingdom to give valid certificates are those whose names appear in the Medical Register. It was asked in this letter that the attention of the authorities in the United States of America might be drawn to the matter, and steps taken to see that certificates given by registered, and therefore legally qualified, persons were accepted whether they were members of the British Medical Association or not. A copy of this letter having been sent to the British Medical Association with an expression of regret that the attention of the Council had not been called to the matter before the announcement appeared, the Association replied that the action of the American Consulate was entirely spontaneous and was not due to any representations from the Association. It was added that any person or body employing medical practitioners would have complete liberty to employ such practitioners as they thought fit, and that no regulation was known which would prevent the American Government, or any other body, from deciding for reasons which seemed to them good to employ only specified practitioners. The Royal College of Physicians of London also drew the attention of the General Medical Council to the matter, and pointed out that the proposed limitation of the right of giving medical certificates to intending immigrants to the United States to medical practitioners who were members of the British Medical Association involved an injustice to those members of the profession who were not members of the Association by prohibiting them from exercising a branch of professional work. The Royal College suggested that the immigration authorities of the United States should be fully informed of the status of the British Medical Association and of the injury which the proposed arrangement would inflict on medical practitioners in this country who were not members of the Association and who would be precluded from giving medical certificates even to intending immigrants who were their own patients, and also of the consequent hindrance to efficient certification as required by the immigration authorities of the United States. The reply of the American Consul to the General Medical Council on Nov. 3rd made it clear that the situation was the result of a misunderstanding. The authorities in the U.S.A., wrote the Consul, never specified that immigrants from England should be examined by members of the British Medical Association. The only stipulation was that the examiners should be qualified and reliable. He added that it was probable that the British Medical Association inferred from a request sent to it for a list of its members that they only would be permitted to examine such immigrants, but the examination was not limited to such members, and the Consulate-General would be glad to give every consideration to examinations made by "your members" (i.e., presumably all registered practitioners). It was not with any intention of discriminating against these others that a list of members of the British Medical Association had been requested.

STOPES *v.* SUTHERLAND: A PETITION TO THE LORD CHANCELLOR.

The principal judgments delivered in the House of Lords in the final appeal in the action brought by Dr. Marie Stopes against Dr. H. G. Sutherland for libel were published at some length in THE LANCET of Dec. 6th (p. 1192). There has since been received here the copy of a petition, presented to the Lord Chancellor by Dr. Stopes, in which she states that the intention of the jury, as explained to her solicitor, since dead, was to find in her favour and to award damages, and that the jury had been dismissed without having the opportunity to explain their intention to the Lord Chief Justice. The petition then states, "your Lordships, therefore, were not acquainted, as you should have been, with the fact that the main stings of the libel (viz., the very serious charges that the methods used at my clinic are harmful and that my propaganda is criminal) were *not* considered by the jury as being matters of fact, but as among the matters of opinion for which damages were awarded to me: the true facts in the libel being that I did found a clinic and did there give information to the poor." Reference to the judgment (THE LANCET, Dec. 6th, p. 1193) will show that the Lord Chancellor, in his judgment, had no hesitation in treating the two matters mentioned by Dr. Stopes as questions of fact, a point which is for the Court and not for the jury to decide. Clearly, also, the House of Lords did not consider the fact that Dr. Stopes founded a clinic and there gave information to the poor to be a matter submitted to the jury as forming part of the matter alleged to be defamatory.

FRAGMENTS OF GLASS IN FOOD AT A RESTAURANT.

In an action tried recently by Mr. Justice McCardie and a common jury, Mrs. Esther Davis, a telephone operator, was awarded £130 damages, with costs, against Messrs. R. E. Jones, Ltd., of Swansea, proprietors of a restaurant in which the plaintiff ate a meal on New Year's Day. A mince-pie was served to Mrs. Davis, who stated that it contained broken glass which at the time made her gums bleed, and which caused her pain in the chest and abdomen on the following day, since which she had had medical treatment. The claim was based, firstly, on the allegation that the defendants were negligent in sending out to their restaurant a mince-pie containing broken glass, and, secondly, upon a breach of the implied warranty on their part that the mince-pie was reasonably fit to be eaten. No evidence was called for the defence, but it was contended that there was no evidence of danger to life, or proof that the plaintiff had, in fact, swallowed any of the glass. Mr. Justice McCardie, in summing up, directed the jury that there was clearly negligence on the part of the defendants and also a breach of warranty. The question of the amount of damages would be affected if they found that the plaintiff had swallowed some of the glass.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Irish Free State and the Medical Register.

THE licentiates who received their diplomas last week from the Royal Colleges of Physicians and of Surgeons must have been somewhat puzzled to reconcile the statements made to them by the respective presidents. At the College of Surgeons, Mr. Maunsell advised them to make all speed to the office of the Branch Registrar to register their diplomas, lest the Register should be closed against them. "Closed it will be," he went on, "unless a few broadminded statesmen appear before it is too late." On the other hand, at the College of Physicians, Sir William Thompson announced that he had the authority of the Government for saying that negotiations on the subject of the Register were proceeding between the Irish Government and the British Government, and that there was every hope that they would end satisfactorily. As a matter of fact, it is understood that the only difference between the two Governments is on a matter of phraseology in the drafting of the identical legislation which has to pass in both countries. There is every reason to suppose that this will be satisfactorily settled as soon as the legal advisers of Mr. Baldwin's Government have time to look into the matter. There appears to be little justification for the pessimistic utterance of the President of the Royal College of Surgeons, an utterance which has given new material to such newspapers as are trying to scare students from the Dublin schools.

Appointments to the Poor-Law Service.

It has been known for some time that the Department of Local Government and Public Health is dissatisfied with the present method of filling medical vacancies in the public dispensary service. In too many cases the choice is made by the local authorities on political or family grounds, even when more corrupt motives are not at work. The medical profession has long demanded that all medical appointments in the public service should be made as the result of competitive examination, and this proposal has been adopted by every Commission and committee of inquiry which has considered the question during the past 20 years. Either as a compromise with this or as a temporary measure it is believed that the Ministry of Local Government is anxious to take medical appointments out the hands of the local authorities, and to entrust them to an appointments board, which, consisting in the main of medical practitioners, would be competent to assess the claims of candidates from the professional point of view. An opportunity of testing this method of appointment by way of experiment has just occurred in Dublin. The Dublin guardians had been suspended from their duties several months ago by the Ministry and their functions are being performed by paid Commissioners. Three vacancies for medical officers had occurred in the union, and the Commissioners invited the several licensing bodies in Dublin to form an advisory committee by nominating one member each, the chairman of the committee to be the chairman of the General Council of County Councils. The Commissioners bound themselves to accept the recommendations of the advisory committee. The appointments were made recently, and a fairly full report of the proceedings of the Advisory Committee has been published. It is stated that the committee consisted of Sir Arthur Chance (representing the Royal Colleges of Surgeons and Physicians), Prof. A. F. Dixon (Dublin University), Prof. E. P. McLoughlin (National University), Dr. H. W. Mason (Apothecaries' Hall), and Senator P. W. Kenny, chairman. There were 64 candidates for the three vacancies, and by a process of continuous selection these were weeded down to five, who were then personally interviewed. Among the candidates finally selected was one lady. It is further stated that a resolution was proposed and seconded, but ruled out of order, to the effect that a man would be more acceptable to the great majority of Dublin dispensary patients than a woman of equal professional attainments. It is unfortunate that any of the members of the Advisory Committee should have tried to engage this committee in matters clearly outside its terms of reference. Moreover, as all licensing bodies in Ireland are open to men and women on the same terms, it is an anomaly that representatives of some of the licensing bodies should attempt to place medical women at a disadvantage with men in a public service.

The Apothecaries' Hall of Ireland.

A Bill presented by the Apothecaries' Hall of Ireland came recently before a Joint Committee of the Senate and the Dail. The object of the Bill was to empower the Hall to designate its licentiates as "Licentiates in Medicine and Surgery of the Apothecaries' Hall," instead of, as at present, "Licentiates of the Apothecaries' Hall." The Bill was unopposed. After the hearing of evidence the Joint Committee found unanimously that the preamble of the Bill was not proved to their satisfaction.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Prof. J. Bergonié.

Prof. Bergonié, director of the anti-cancer clinic at Bordeaux, whose work in radiology is well known, and who has been seriously ill for some time following the amputation of an arm, as the result of injuries sustained in the course of his radiological work, has recently been awarded, by the decree of the President of the Republic, the insignia of the Grand Cross of the Legion of Honour—the highest grade in that honour. The decoration was handed to Prof. Bergonié by Mr. Strauss, former Minister of Hygiene, in the presence of Profs. Proust and Roussy, of the Faculty of Medicine of Paris; and it bore the following inscription: "Although he was perfectly familiar with dangers of the prolonged exposure to X rays, he devoted his life to the study of their properties, and pursued his researches indefatigably with the unshaken will to benefit science by the discoveries of which he was the heroic victim, in the hope that humanity would enjoy the fruits of his sacrifice." Prof. Bergonié recently made a gift of 100,000 fr. to the Faculty of Medicine of Bordeaux to endow the anti-cancer campaign centre which has been founded there.

Two New Academicians.

Within a fortnight of each other two eminent surgeons, Prof. Félix Legueu and Prof. Jean Louis Faure, were elected members of the Academy of Medicine, and it came as a surprise to many in the medical profession that these two names had not long ago received the honour of inscription on that illustrious roll. Prof. Legueu, who succeeds the late Dr. Jalaguier, was born in Angers (Maine-et-Loire) in 1863. About 12 years ago he was elected to the chair of genito-urinary surgery at the University of Paris in succession to Guyon. His clinic in the Hôpital Necker has been attended by great numbers of students from France and from abroad, and the work of the clinic has been recorded in the *Archives Urologiques*, which Legueu founded. Prof. Faure was elected to the vacancy caused by the death of Dr. Richelot. He was born in the same year as Prof. Legueu, at Sainte Foy-la-Grande (Gironde). During the war he held the post of consulting surgeon to the Fourth Army. Since 1919 he has been professor at the gynæcological clinic at the Faculty of Medicine of Paris, where he has had a large following of students. In addition to his outstanding skill as a surgeon, Prof. Faure possesses great literary talent. He composed the "Hymne à la Paix," and a psychological study "L'Ame du Chirurgien," both of which achieved notable success. Prof. Faure has travelled widely and has done much to maintain the high standard of French surgery in the eyes of the world.

Doctors and Taxation.

Here, as with you, the press in interested at the moment in the income of medical men. In a Bill at present before Parliament there are two clauses which have given rise to comment. The first refers to compulsory keeping of accounts, and the second deals with the control of income-tax returns based on the taxpayer's standard of living. While, for purposes of taxation, commercial houses must furnish a balance-sheet of their income and expenditure, there is no legal obligation at present for any member of one of the learned professions to publish a balance-sheet showing his financial standing. The proposed Bill will make it obligatory in the future for professional men to keep an annual register containing a full statement of sums accruing to them from their professional duties, balanced against professional expenses. This book must be open to inspection at any time by the Tax Commissioners under penalty of a fine. As regards the income-tax, the Commissioner finds that at present it is often impossible to assess the tax on a higher rate of income than that returned by the taxpayer, although such return is obviously not in accordance with the taxpayer's standard of living. The proposed Bill would fix a minimum rate of income, based on the external evidence of the taxpayer's fortunes, as evidenced by the rent of his premises and his general air of prosperity. If the annual return made by the taxpayer falls below this figure, the return will be considered insufficient. In such a case the taxpayer must prove to the Commissioner the exact state of his income, and, if he cannot do so, he will be taxed on the sum assessed on the evidence of material prosperity. The general assembly of the Union of the Medical Syndicates of France, an association which numbers some 16,000, has unanimously passed a resolution that a doctor should not be taxed on the basis of external evidence of wealth, for in many cases these external signs do not correspond to his real position. It is pointed out also that the learned professions, taken together, compose only a very small part of the taxpaying public (hardly 100,000 individuals) yet they pay 48 millions in taxes, as compared to agricultural labourers whose number runs into millions but who nevertheless do not pay more than 42 millions.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

High Hospital Fees and Lack of Clinical Material.

WITHIN the last few days a conflict on important issues has taken place between the Ministry of Health and Prof. Josef Meller, the well-known ophthalmic surgeon, head of the first Vienna eye clinic, arising from certain criticisms expressed by the professor on the methods employed by the administrative staff of the General Hospital in connexion with the payment of the hospital fees by patients. It appears that during one of his regular lectures Prof. Meller declared before his students that he would no longer tolerate the dismissal or non-admission of patients on the grounds that they were unable to pay the rather high fees which are now charged. From the teaching point of view he complained bitterly that clinical material was not available, in spite of his urgent request, because would-be patients as a whole were poor foreigners and could not pay treble the ordinary fees as charged them by the administrative officers; also that patients who had been admitted as third-class patients were forced to pay first-class fees and were thus driven away before they were cured. Naturally such methods would ruin the reputation of the Vienna General Hospital, of which the eye clinic is a part, and would impede useful teaching. Prof. Meller's repeated remonstrances to the authorities had hitherto been of no avail, and so he was forced to turn to the public for assistance in his fight against bureaucratism and "red tape." These accusations caused some consternation amongst the public the officials in the hospital and in the Ministry charged with the control of the hospital public feeling supported the professor. But the affairs. The press took the matter up, and, of course, answer given by the administrative staff and the Ministry was evasive, and did not satisfy Prof. Meller. So he declared that unless definite satisfaction was given him he would resign his post and leave Vienna altogether. The students and the teaching staff of the medical faculty took Prof. Meller's part, and exerted all possible influence to retain him by urging the Ministry to arrange matters in a mutually satisfactory manner. Up to the present, however, this has not borne fruit, and as Prof. Meller has received very flattering offers from a number of American and German universities there is great danger of his leaving Vienna. The attitude of the Ministry shows what kind of spirit prevails amongst our administrative officials in regard to science and teaching.

Cancer and Tuberculosis Mortality Statistics.

The new "Statistical Yearbook of the City of Vienna" contains a report on the last nine years in which the International Bertillon index of ætiology of death has been employed. This is the first report since the war, and is very complete and thorough. The following figures may be quoted. In 1923 there died 25,480 persons in this city—12,756 male, 12,724 female. Tuberculosis claimed 4630 victims, or 18 per cent. of the total deaths; cancer killed 2824, or 11 per cent. The absolute number of deaths has diminished within the last three years, because from 1915–20 the influence of the war was still felt, as well as the disastrous economic conditions. A very instructive series is the following :—

Year	Total mortality.	Tuberculosis mortality.	Year	Total mortality.	Tuberculosis mortality.
1915	37,018	7,810 (21 %)	1920	34,179	7,464 (21·8 %)
1916	37,631	9,651 (25·6 %)	1921	28,297	5,265 (18·6 %)
1917	46,131	11,741 (25·4 %)	1922	30,068	5,552 (18·4 %)
1918	51,497	11,531 (22·3 %)	1923	25,480	4,630 (18·1 %)
1919	40,932	10,606 (25·9 %)			

It appears that the energetic and decided action of the municipal officers of health against tuberculosis is at last effective, as shown by the constant decrease of the mortality due to this disease. As regards cancer similar tables may be quoted.

Year.	Cancer deaths.	Percentage of total.	Year.	Cancer deaths.	Percentage of total.
1915	2846	7·6	1920	2423	7·0
1916	3091	8·2	1921	2618	9·2
1917	3040	6·5	1922	2769	9·2
1918	2672	5·1	1923	2824	11·0
1919	2604	6·4			

Here we find that contrary to tuberculosis cancer is steadily increasing as a cause of death.

Census and Health of Prostitutes.

An exact census of all the women registered at police headquarters as prostitutes is taken regularly every two or three years, and when this fell due a short time ago the medical staff provided for a "health census" also. The number of girls on the list was 1052, against 1287 in January and 1349 two years ago. But it must be kept in mind that at least an equal number may be classed as clandestine prostitutes. In the ten months of 1924, 116 girls had taken out new books; their age was 18–27; no female below 18 is taken on the list. In fact, the majority of the prostitutes are rather older than one should expect, as the age-group of 25–35 years amounted to over 40 per cent. of the total, and from 35–45 years 25 per cent. No more than 10 per cent. were below 20 years, and from 20–25 years the percentage was 16. The remaining 9 per cent. were between 45 and 61 —this being the elderly limit on the list. At the time of the control census, 16 per cent. were manifestly affected with gonorrhœa, 3 per cent with manifest syphilis, whilst out of the total only 2 per cent. had not been proved at some time to have had venereal disease. "Latent" gonorrhœa or syphilis was known to be present in nearly all the subjects. It is interesting to note that the new applicants were also already infected, for no less than 90 per cent. of them required medical treatment. As regards tuberculosis, in quite 28 per cent. the apices were found affected, and in 12 per cent. advanced disease was present, so that the spread of the "morbus Viennensis" by these girls was no insignificant menace.

Can a Woman Doctor Practise as a Midwife?

A curious problem has arisen recently here as the direct outcome of the miserable economic situation of the medical profession. A woman doctor, who had tried without success to earn her living as a general practitioner, resolved to qualify as a midwife by taking the prescribed course at a training centre. Whether she will be allowed to practise under both qualifications is doubtful. It seems rather hard to credit the alleged statement that she was not able to obtain the necessary instruction in the art of the midwife during her career as medical student, and must perforce learn it along with the midwives.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives health statistics of seven administrative counties and the Island of Guernsey for 1923 :—

Name of district.	Estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population. All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Death-rates per 1000 births. Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Derbyshire ..	600,000	21·1	10·7	0·75	1·0	1·8	36	75	5·0
Somerset.. ..	392,300	17·4	11·3	0·90	1·4	1·5	24	46	2·5
Gloucestershire	331,800	17·9	11·7	0·86	1·3	1·6	25	48	4·4
Norfolk	318,970	18·6	11·7	0·81	1·5	1·4	31	58	3·0
Lincolnshire (Parts of Lindsey) ..	256,600	20·3	11·5	0·96	1·3	1·9	30	62	3·1
East Sussex ..	255,998	15·1	11·2	0·91	1·6	1·4	23	45	2·8
Isle of Ely ..	75,250	20·1	12·3	0·77	1·8	1·9	34	66	6·0
Guernsey.. ..	38,200	20·8	14·2	1·60	1·3	1·2	31	73	1·3

Derbyshire.

Dr. Sidney Barwise reports that there have been 1634 cases of small-pox in Derbyshire since 1921 without a single death. There has been no change of virulence during the last four years, and Dr. Barwise assumes that the African or alastrim variety of small-pox breeds true to type. A scheme has now been approved for the provision of 50 beds at Bretby Hall for early bone and joint cases of tuberculosis in children and young adults. Hitherto such cases have been sent to Oswestry with most encouraging results, and the health committee are unanimous in their desire to provide treatment for such cases in their own area at once. Dr. Barwise considers that the results obtained by treating bone and joint cases are to-day the one bright spot in the treatment of tuberculosis. Every form of treatment recommended for pulmonary tuberculosis is carefully investigated in the Derbyshire sanatoriums, but Dr. Barwise feels that if good results are to be secured, the advanced cases must be, to some extent, jettisoned, as we cannot afford to fill the sanatoriums with patients who have no chance of ultimate recovery. Dr. A. Niven Robertson, the tuberculosis officer, gives particulars of the scheme of graduated labour and rest adopted in the sanatoriums, and mentions that the most recent methods suggested by Dr. Leonard Hill for getting the full benefit of fresh air have been adopted. Various records of kata-thermometer readings have been kept since January, 1924. The quartz-lamp treatment has given beneficial effects in glands of the neck, lupus, and the tuberculides. Good results are also obtained by artificial pneumothorax. Two new cases were treated in 1923 and the treatment of five old cases was continued from the previous year. On the other hand, Dr. Robertson records no benefit from the use of Dreyer's defatted vaccine, Raw's bovine vaccine, pneumosan, Spengler's I.K., O.T. inunctions on the lines suggested by Sir R. W. Philip, and Paget's nasal B.E. method. Dr. Robertson thinks that these remedies, like sodium morrhuate, collosol calcium, Yadil antiseptic, Koch's tuberculins, and the host of other tuberculins, will probably pass into a deserved oblivion.

Dr. Barwise deals at length with the question of goitre. He points out that the disease is usually prevalent in mountainous districts at a distance from the sea. He does not find that goitre is more prevalent in the districts of Derbyshire supplied with limestone water than in the districts supplied by moorland surface water, and water from the coal measures, and the Bunter sandstone. The relation between a deficiency of iodine and the occurrence of goitre is thoroughly discussed. The good preventive results obtained by the administration of iodine in Switzerland are mentioned, and figures quoted for the canton of St. Gallen showing that during the last three years the percentage of goitre among the school-children has decreased from 87·6 to 13·1, following the use of chocolate tablets containing an organic form of iodine. Dr. Barwise mentions the three ways in which the problem may be tackled. First, by the iodisation of the water-supply as in Rochester, U.S.A.; secondly, by the use of iodised salt; and thirdly, by the use of iodised sweets or chocolates. He emphasises the fact that the problem is much more than the prevention of simple goitre and implies, in addition, the control of various forms of physical and mental degeneration, such as cretinism, mutism, and idiocy, dependent upon thyroid insufficiency.

Dr. Barwise also thinks that the freer use of iodine in Derbyshire would lead to a greater freedom from infectious complaints and an improvement in the general health. He sums up the situation by saying that the time has now arrived when "Derbyshire neck" can, by simple procedure, be made a thing of the past.

During the first six months of 1924 there was a great increase in the number of cases of encephalitis lethargica. Thus, up to the end of June 64 cases had been notified as compared with an average of about ten for the three preceding years. The present condition, says Dr. Barwise, is serious, both on account of the 48 per cent. case-mortality and the after-effects on the moral character and physical condition of survivors. Dr. Barwise points out that the technique in the treatment of syphilis has been much simplified by the substitution of intramuscular for intravenous injections. In consequence he is more hopeful as to the future, as syphilis can now be more readily treated by the general practitioner.

Dr. Barwise feels sure that the Milk and Dairies Amendment Act, 1922, has acted as a stimulus to the production of cleaner milk, although no work has been done in the county directly under the Act. During the present year the agricultural committee have offered prizes for a clean milk competition and details of the tests devised for the competition are given. During 1923, 282 mixed milks were examined for the presence of tubercle bacilli, and 22, or 7·8 per cent., were found to be infected. The report concludes with health notes drawn up at the suggestion of the Derbyshire Insurance Committee.

Somerset.

Dr. William G. Savage reports that in April, 1923, the Ministry of Health constituted the county council the authority for providing isolation for small-pox in the administrative county, excluding the boroughs of Chard and Yeovil and the rural district of Chard, which already possessed accommodation for small-pox. The county council have obtained one site for a small-pox hospital for the northern part of the county at Chew Magna and a second site at Cossington for the southern. On the latter site an eight-bed small-pox hospital and a motor ambulance have been provided, on the northern site as yet only a water-supply. It is intended to use the small-pox hospital for isolated cases or for the first few cases of an epidemic and to provide additional accommodation on the two sites as needed. Only two cases of small-pox were notified during the year; one was not diagnosed until he had left the county and the other was treated at home. There has been a noteworthy decline in the deaths from measles, especially in the last two quinquennia. Dr. Savage attributes this, in part, to educative public health work. There are two lines of attack—namely, the effort to secure postponement of the disease, and secondly, the instructions of the parents of patients as to the dangers of neglect. The county health visitors have worked on these lines since 1917.

Dr. Savage draws a contrast between the decline in the death-rate from pulmonary tuberculosis during the present century and the failure to decline of the death-rate from non-pulmonary tuberculosis during the same period, and says the contrast is hardly to be wondered at seeing that a considerable proportion of non-pulmonary tuberculosis is due to milk and that nothing is being done to deal with this source of infection. During 1923 the deaths from pulmonary tuberculosis were 23 less than in 1922, whereas the deaths from non-pulmonary tuberculosis were 11 more. The county council are, however, beginning to take active steps with regard to the milk-supply, and are now empowered by the 1922 Act to take over, with the approval of the Ministry of Health, the duties of a defaulting local authority. Dr. Savage has drawn up a milk report score-card, mainly with the idea of educating the milk-producers and purveyors throughout the county. Work under the various Milk Orders has never been properly done in the past, he says, and has been largely a farce. The authorities vary very much now in the zeal and thoroughness with which they undertake the work. During the present year a number of demonstrations on the production of clean milk have been given, with the help of the agricultural committee and the Agricultural Institute at Cannington, and have undoubtedly done good. It is also proposed to hold an extensive clean milk competition. Dr. Savage would like to see the principle adopted that the agricultural department of the county council should concern itself with raising the standard for clean milk production and that the public health inspection side should especially deal with the minority of very neglectful milk-producers. He does not think that the production and sale of graded milks will make much headway until further education of the consumers has been effected. The county council has suggested to the local authorities that no purveyor of milk should be registered unless he has efficient means for cleansing his vessels by steam or boiling water, a suitable place for storing his milk vessels, and a suitable place for storing his milk.

Dr. Savage reports that there are still a good many rural parishes and some larger urban areas with an insufficient or unsatisfactory water-supply. Further steps were taken during the year to compel the owners of milk depôts to cease the pollution of streams with milk washings. It is a much more difficult matter, Dr. Savage points out, to secure a satisfactory remedy for pollution by whey. An analysis of the Census figures of 1911 and 1921 indicate a definite deterioration of housing accommodation. In addition to the scarcity of houses, there is great difficulty in getting repairs carried out, partly owing to the shortage of skilled workers and partly owing to the low rentals obtainable. Dr. Savage urges the importance of town-planning, especially for seaside resorts, and points out that every urban area with a population over 20,000 must prepare a scheme by the end of 1925. The medical officer of health of Minehead (population 5181) has drawn attention to the need for a comprehensive scheme for his district.

Gloucestershire.

Dr. J. Middleton Martin states that the outbreak of small-pox which began at the end of 1922, persisted in one part of the county until May, 1924. The total number of cases reported was 419, and there was one death. During 1923 the public health committee decided to undertake, with the assistance of the National Milk Publicity Council, a milk campaign. The campaign has been carried out during the present year, and was inaugurated, by a meeting of all interested, in the Shire Hall in April, 1924. This has been followed by addresses in the schools and to various organisations, such as girl guides, boy scouts, and women's institutes, by demonstrations on the production of clean milk at various farms, and by public meetings in the larger centres. A clean milk competition is to be held during the winter. The Gloucestershire scheme for the extension of medical services is making smooth progress. It is gradually enlarging its scope so as to cover the whole administrative county, and orthopædic treatment has now been added to the services available.

Norfolk.

Dr. J. T. C. Nash would like to see all forms of tuberculosis treated under one administration at Stanninghall by the addition of an admission block. If this were done a resident medical superintendent and a larger nursing staff would be necessary, but against this there would be a saving of the expenditure at present incurred in sending patients away to other institutions. He thinks surgical tuberculosis could be treated at Stanninghall by calling in the aid of the surgical staff of the Norwich Hospital, or that it might be preferable to have an ad hoc institution for the treatment of all forms of crippling. Dr. Nash points out that most of the houses built during the last few years are out of reach of the slender resources of the agricultural labourer. A considerable number of old railway carriages are being converted into dwellings and there is much to be said, he thinks, for this cheap substitute for ordinary houses, when the cost of building is prohibitive and the shortage of houses acute; but sanitary authorities will need to ensure that a wholesome water-supply is available and that no nuisance is created.

Lincoln: Parts of Lindsey.

Dr. R. Ashleigh Glegg reports that the little children have suffered from the cutting down of the milk grants. This is to be met by raising the income limit to the level of 9s. per head for families with one child only and by the allowance of milk at below cost price in necessitous cases for infants up to 3 years of age. There is a need for the increase of the dental staff and a recommendation for the appointment of a third dentist by the education and health committees jointly is under consideration. The county council acts as isolation hospital authority for the north of the county, but the proposal to erect a hospital at Brumby was rejected by a small majority, and Dr. Glegg strongly urges the council to reconsider its decision. Branston Hall, a large mansion, situated about four miles from Lincoln, with 100 acres of park and gardens, was purchased by the council two years ago for use as a sanatorium. It was intended to provide accommodation there for the three administrative counties of Lincolnshire and the borough of Grimsby, by using the hall for women and children and by erecting a pavilion for 50 men. The Ministry of Health agreed to the proposal in May, 1921, but two months later asked the council to postpone the erection of the pavilion on the grounds of economy. The hall was opened for the reception of women and children on Jan. 4th, 1923. There are five shelters available for women and accommodation is provided for 35 women and 35 children. Dr. Glegg points out that there is also great need for a hospital for advanced cases and for the provision of treatment for bones, joints, and glands. In view of the half-hearted way in which many of the district councils are dealing with housing difficulties, Dr. Glegg thinks the county council should erect some good houses to be let to families attacked by tuberculosis at rentals similar to what they are at present paying for the insanitary and overcrowded dwellings which many of them inhabit.

East Sussex.

Dr. Alex. G. R. Foulerton says that an adequate remedy for the continuing shortage of houses is not likely to be found by the local sanitary authorities. Most of the additional accommodation provided so far has been the result of private enterprise, and it is to subsidised private enterprise that he looks for improvement in the future. Up to the present maternity beds have been provided at the Brighton Women's Hospital and the Crowborough Cottage Hospital. It is hoped that during the current year additional beds will be secured for the use of the county at the recently opened maternity home at Hastings. The cases for which the committee endeavours to provide hospital treatment are: emergencies during confinement, cases where difficulty is apprehended during pregnancy, cases where home conditions are unsatisfactory, and cases where the woman is living in a remote part of the county.

Isle of Ely.

Dr. J. Pixton Walker tells us that at the recent Census the Isle of Ely had a higher proportion of agricultural workers than any other portion of England and Wales—namely 481 per 1000 occupied males. There are clinics for tuberculosis at Ely, March, and Wisbech, but there is no hospital or sanatorium in the administrative county. The council reserves four male and one female bed at Ipswich sanatorium. It has not been considered advisable to increase this number of beds, because it is found advantageous for climatic or other reasons to send tuberculosis cases to hospitals or sanatoriums in various parts of the country. Venereal diseases are treated at Addenbrooke's Hospital, Cambridge, and rail fares are paid by the council for necessitous cases. Several districts in the county have not made any hospital provisions for small-pox. Ten cases of typhoid fever occurred in the borough of Wisbech, but no cause could be assigned for them.

Guernsey.

Dr. H. Draper Bishop states that the chief industry of the island is the growing of tomatoes, grapes, and other fruit, vegetables, and flowers, chiefly under glass, for export. Another important industry is the export of granite for road-making. During 1923 19,241 tons of tomatoes, 1619 tons of flowers, 1675 tons of grapes, 2230 tons of vegetables, and 185,740 tons of granite were exported. A third industry is the rearing of Guernsey cattle for sale in England and the U.S.A., and these cattle are highly prized not only for their rich milk, but "above all for their freedom from tuberculosis." The water-supply of Guernsey, derived from deep wells, is the property of the Government of the island. The average yearly hours of sunshine from 1903 to 1922 were 1902·8 hours, and during 1923 the record was 1893·4 hours.

Dr. Bishop comments on the unusually high death-rate from tuberculosis during the year, but the average for the years 1906–22 is also higher than one would expect in an island so favourably situated as Guernsey. Dr. Bishop, however, points out that all is not well with regard to housing matters. Accommodation was provided for 18 families during the year and "the States have realised their great responsibilities in the matter and shown an earnest determination to improve the home conditions of those unfortunate people who are now living under conditions most prejudicial to their well-being." Diphtheria, which has been prevalent recently, was less prevalent than in the two preceding years. As the result of a fatal case which was overlooked until a few hours before death, eight cases were notified from one family which was living in most insanitary and overcrowded conditions.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 29TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 122; scarlet fever, 2294; diphtheria, 1092; enteric fever, 59; pneumonia, 1193; puerperal fever, 47; cerebro-spinal fever, 8; acute poliomyelitis, 20; acute polio-encephalitis, 2; encephalitis lethargica, 52; continued fever, 1; dysentery, 21; ophthalmia neonatorum, 113. There were no cases of cholera, plague, or typhus fever notified during the week. Of the cases of small-pox, 12 were notified from the county of Chester (Dukinfield 8, Stalybridge 4), 54 from Derbyshire (Derby 37, Bolsover 4, Chesterfield 4, Chesterfield R.D. 9), 16 from Yorks. N. Riding (Middlesbrough 15, Eston 1). Six of the cases of dysentery were notified from ports (Barry 5, Plymouth 1), the remainder from Woking 8, Bristol 4, Alfreton (Derby), Southall-Northwood, and Wallsend 1 each.

Deaths.—In the aggregate of great towns, including London, there were 2 deaths from enteric fever, none from small-pox, 8 from scarlet fever, 20 from diphtheria, 57 from measles, 67 from influenza. In London itself the deaths from diphtheria numbered 8, from infantile diarrhœa 23.

THE GENERAL MEDICAL COUNCIL.

AT the concluding sitting of the winter session of the Council on Friday, Nov. 28th, it was announced that the Registrar had been directed to restore to the Medical Register the names of Charles Harold Bennett and David Arnold Chaning Pearce. At the same sitting the reports of a number of Committees were received and approved.

Public Health Committee.

This Committee reported that most of the licensing bodies which grant a diploma in public health had complied with a request to submit copies of their new regulations. The Committee were satisfied with the majority of the answers received; in other cases they had arranged to address inquiries to certain licensing bodies. When answers had been received to these inquiries, the Committee would submit a report to the Council.

Pharmacopœia Committee.

This Committee reported that the number of copies of the British Pharmacopœia, 1914, sold in the year ending Nov. 24th, 1924, was 2279, practically the same number as in the preceding year. The total number sold since the date of publication was 48,067. The stock remaining on hand was reduced to less than 900 copies. The Committee was authorised to issue a further impression of 5000 copies, taking the opportunity to make any necessary typographical corrections. Under certain reserves, the British Government had decided to send delegates to the proposed International Conference on Unification of Formulæ, to be held at Brussels in 1925, and Sir Nestor Tirard had been nominated to attend on behalf of the Council.

Education Committee.

This Committee had considered the inclusion of parasitology in the medical curriculum, and the matter would be brought up for further consideration when the next reprint of the resolutions of the Committee was made. Request had been received from the University of New Zealand that the Council would consider favourably the substitution of an accrediting system in lieu of the matriculation examination as the qualification for entrance to the University. The Committee resolved that in each case it would have to be shown that the New Zealand certificate had been accepted by one of the Universities in this country. Satisfactory evidence as to visitation having been received, Christ's Hospital was added to the list of institutions recognised by a licensing body, and approved by the Council. The Registrar reported that, since May last, the registration of 97 medical students had been antedated in accordance with precedent. Of these, 49 were registered in England, 43 in Scotland, and 5 in Ireland. The registration of 41 dental students had also been antedated.

Examination Committee.

Since May members of this Committee had visited the intermediate (anatomy and physiology) examinations of several additional bodies. The Universities of Oxford, Leeds, Liverpool, Bristol, and Wales, and the Apothecaries' Hall of Dublin had not yet been visited, but the Deans of their Faculties of Medicine and a member of the Council, Dr. Magennis, had supplied information showing the amount of time allotted by each of the licensing bodies to the written, oral, and practical examinations on the subjects concerned. This return shows that the amount of time allotted to the written examination in anatomy varied between two hours and six hours, when two papers were set, and to the oral and practical examinations from ten minutes to three hours. The length of the written examinations in physiology varied from one and a half hours to six hours, while the oral and practical sections of histology, biochemistry, and experimental physiology were together allotted in one case as little as ten minutes and in another 11 hours. Attention was drawn to the fact that No. 6 of the Council's recommendations—viz., "Except in subordinate parts of the examination there should always be two examiners participating when a candidate is undergoing any kind of oral examination," was not strictly observed by all the bodies. At a previous meeting of the Council the Registrar had been directed to ask the bodies whether they did or did not take into consideration class work and class records. Most of the bodies had now replied. The English Conjoint Board, the Apothecaries' Society, the University of Cambridge, the University of London, the University of Birmingham, and the Scottish Conjoint Board answered in the negative. Affirmative replies came from the Universities of Durham, Liverpool, Leeds, Sheffield, Glasgow, Aberdeen, St. Andrews, and Dublin. The University of Oxford had the matter under consideration; in Manchester class work was considered in certain subjects but not all; in Edinburgh only when there was doubt as to whether candidates should pass or fail. The National University of Ireland reported that it had been adopted in Dublin, but in Cork only in the border-line cases.

Dental Education and Examination Committee.

A report on the examination of the Royal College of Surgeons of England had been circulated for the information of the Council. The only remaining reports to come in were those of the Royal College of Surgeons in Ireland, the Universities of Durham, Birmingham, St. Andrews, Sheffield, Belfast, and the National University of Ireland. With the exception of Birmingham these have all been inspected, but the bodies concerned had not yet supplied their observations. The inspector was being asked to make a general report on the result of his inspection for presentation to the May session. In view of the amended recommendations for the dental curriculum the Committee was communicating with all the colonial and foreign recognised qualifying bodies to ascertain if their requirements had been brought into line with those of the Council.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. J. D. S. Milln is placed on retd. list with rank of Surg.-Capt.

ROYAL ARMY MEDICAL CORPS.

Col. R. J. W. Mawhinny, late R.A.M.C., having attained the age for compulsory retirement, is placed on ret. pay.

Lt.-Col. and Bt. Col. G. J. A. Ormsby, from R.A.M.C., to be Col., vice Col. R. J. W. Mawhinny, to ret. pay.

ARMY RESERVE OF OFFICERS.

Lt. F. W. Oldershaw, late Serv. Bns., Lincoln. R., to be Lt.

TERRITORIAL ARMY.

The King has approved of the following appointments:—To be Hon. Surgeon to His Majesty: Col. F. Kelly, in succession to Col. J. Clay (retd.). To be Hon. Physician to His Majesty: Col. A. B. Soltau, in succession to Col. C. P. Oliver (retd.).

ROYAL AIR FORCE.

The undermentioned are granted short service commissions as Flying Officers: W. A. Beck and J. Parry-Evans.

Correspondence.

"Audi alteram partem."

THE ALLEGED STERILITY OF PRESENT-DAY BACTERIOLOGY,

To the Editor of THE LANCET.

SIR,—Since the recent developments in the teaching of bacteriology in this University have been referred to in the correspondence under the above heading, and in the address by Prof. A. E. Boycott which was its origin, I should like to remove any possible misunderstanding of our present arrangements, or of the ideas on which they are based.

Medicine is the mother of the sciences, and her fecundity can hardly have been surpassed by the old woman who lived in a shoe, whose embarrassments she shares. Bacteriology is one of the youngest of the brood, but no one can question its parentage. I am sure that Prof. Boycott does not wish to see the baby abandoned on the doorstep of the botanical department. He is simply calling attention to the fact, so often overlooked by parents, that the child is growing up. If I read his address aright, I take it that he is suggesting that bacteriology is based on too narrow a foundation, and that it is unlikely to develop healthfully until that foundation is broadened. He suggests that there is need for a study of bacteria as living things, regarded as a whole, and not particularly from the point of view of their interference with man and his domestic animals, or with his commercial pursuits; for any suggestion that bacteria are to be studied in the curious vacuum depicted by Prof. J. C. G. Ledingham, I have searched in vain. Prof. Boycott seems to think that one of the most convenient homes for bacteriological study of this type would be in, or in close association with, a department of botany. In both conclusions I find myself in close agreement with him, but I do not think, nor I believe does he, that the matter ends there.

That very much would be gained by a purely botanical study of bacteria I have no doubt at all, and if botanists would extend their activities into this field I believe that all present-day bacteriologists would wish them well, and wait with some eagerness for the results. But most of us, who have entered the bacteriological field by the medical road, have no wish to forget our past journey; indeed, many of us would be ill-equipped for those very studies in which the botanist would excel. Prof. Boycott's address was given at the opening of a new institute of pathology, and it was, I think, clearly in his mind that the study of infectious processes was likely to be a serious loser by our inadequate knowledge of many of the fundamental facts about bacteria, on which such study must be based. That there is, in fact, an urgent need, especially perhaps in this country, for a broadening of the basis of bacteriological training will hardly be denied. For emphasising this need, I feel that all of us who are interested in the welfare of our science owe Prof. Boycott a debt of gratitude.

I do not think that the following propositions will be denied by any of your correspondents: (1) That the training in bacteriology given in the course of the medical curriculum is, and must remain, too incomplete and too specialised to form any sound basis for a bacteriological career. (2) That while the student, in his later years or after qualification, can readily obtain further training in bacteriological methods, in the laboratories attached to our teaching hospitals, such training is, quite rightly, mainly confined to bacteriology in its immediate relation to human disease. (3) That, if anyone wishes to take up any branch of bacteriology as a serious study, he should be given facilities for obtaining an adequate training in the general principles of the subject.

There are two obvious ways in which this object can be gained. Bacteriology can be given a place among the subjects to be studied by a candidate for the B.Sc. degree. This method has obvious advantages, and has been adopted at several universities. A special diploma can be granted, after an adequate course of study and an adequate examination test. This method has the disadvantage that the training cannot be so thorough as in the case of a course for an honours degree. It has the advantage that it is open to post-graduates, and is therefore available to those who are attracted to bacteriological work late in their university career. It is this latter method which we have adopted here in Manchester. The course for the diploma extends over a full academic year, and its essential basis is a thorough study of representatives of all the more important bacterial groups. The successful organisation of this part of our course has been rendered possible by the existence of the national collection of type cultures, in connexion with which we all owe so great a debt to Prof. Ledingham. In addition to this general foundation, each student must take up two or more special branches of bacteriology, adapted to the requirements of medical or non-medical study. We believe that, in this way, it will be possible to turn out students with a sound, if elementary, knowledge of the general principles of bacteriology, of the general characteristics of the more important bacterial groups, and of bacteriological technique.

That the provision of such a basis for their future work will be no small advantage, this correspondence has, I think, already demonstrated.

I am, Sir, yours faithfully,
W. W. C. TOPLEY.

Department of Bacteriology and Preventive Medicine,
University of Manchester, Dec. 5th, 1924.

THE STATUS OF PATHOLOGY.

To the Editor of THE LANCET.

SIR,—I was glad to see that Prof. A. E. Boycott in his address at Montreal advocated the recognition of pathology as a branch of natural science as I have been advocating this for 25 years. It is not to the credit of our universities that they refuse this recognition, while many of them are only too ready to exploit the commercial possibilities of pathology as a source of income. Would Dr. Boycott use his influence with the Royal Society in this matter and also in getting the Pathological Society of Great Britain and Ireland included in the official list of scientific societies? At present, I believe, it is not included. Prof. R. T. Hewlett states that bacteriology is recognised by the London University as a science. If bacteriology is so recognised why not pathology? Some universities recognise that heterogeneous mixture known as public health as a subject for science degrees!

I am, Sir, yours faithfully,
CHARLES POWELL WHITE.

Manchester, Dec. 8th, 1924.

THE EFFECT OF SPLENECTOMY ON THE PRODUCTION OF EXPERIMENTAL PURPURA.

To the Editor of THE LANCET.

SIR,—Dr. Sutherland takes me to task for having gone beyond my experimental evidence in concluding that "Splenectomy cannot be relied on to give any but temporary relief in the treatment of purpura hæmorrhagica." On the whole, I am forced to admit the justice of his criticism, but that my conclusion is as groundless as his letter would make it appear I am not prepared to concede. We are still ignorant of the pathogenesis of purpura hæmorrhagica, but there s reason to suppose that it is produced by the action of some toxin on the platelets and thrombopoietic tissue. The occurrence of purpura, associated with a thrombopenia, in acute infections and the experimental production of purpura in animals by means of bacterial toxins, such as diphtheria toxin, support this contention. Presumably this toxin is the product of some focus of infection, which may be situated in the spleen, but there is no reason to suppose that it is invariably so located. Should the sole toxic focus be in the spleen, then I should expect splenectomy to effect a permanent cure. On the other hand, should the focus be located elsewhere or should there be multiple foci, in the spleen as well as in other tissues, then the effect of splenectomy would be merely of a temporary nature such as I was able to demonstrate experimentally.

Briefly, splenectomy is effective in the treatment of purpura hæmorrhagica not because of the removal of the spleen qua spleen, but because it removes the toxic focus. That this is not pure hypothesis is borne out by clinical experience. Kaznelson himself admits that there are cases of this condition in which splenectomy cannot be expected to effect a cure, and one, at least, of the American cases relapsed after a temporary amelioration. Of course, it might be argued that our insufficient knowledge leads us to group together under the term purpura hæmorrhagica cases which are essentially different in their pathogenesis, and that only those cases which are permanently benefited by splenectomy are really entitled to this term. This is more or less the attitude adopted by Kaznelson and he has produced evidence in support of this contention.

This question, however, still requires elucidating, and it will be mainly from a detailed study of clinical material, including an examination of the spleens removed by the surgeon in so-called cases of purpura hæmorrhagica, both from the histological and experimental point of view, that a correct understanding of these conditions will be arrived at.

I am, Sir, yours faithfully,
London, Dec. 8th, 1924. S. PHILLIPS BEDSON.

THE CLINICAL SIGNIFICANCE OF CONSTIPATION.

To the Editor of THE LANCET.

SIR,—The letter by Dr. E. G. March in THE LANCET of Dec. 6th proves conclusively that stasis and toxæmia cannot be gauged by the number or consistency of the stools. Bismuth X ray examinations show that a patient may have one, two, or more evacuations daily, and may nevertheless harbour stagnant fæces for weeks. Decomposing masses accumulate in the cæcum and ascending colon where they act as irritants and set up catarrh of the mucous membrane—colitis. Fæcal material is carried through the irritated bowel in small quantities mixed with mucus till enough has accumulated in the pelvic colon and rectum to cause an evacuation. There may be several evacuations, but nevertheless the cæcum remains packed, the ileum is unable to propel its contents into the tensely filled cæcum, and the lower ileal coils become a cesspool teeming with micro-organisms which set up intense toxæmia. This state of affairs exists in thousands of our fellow creatures who, consequently, are living on the verge of a breakdown. Not to mention the serious general manifestations of neglected stasis, the local breakdowns in the alimentary tract include such familiar conditions as appendicitis, gallstones, gastric and duodenal ulcer, and, worst of all, cancer. To the unobservant these troubles seem to come as "bolts out of the blue," for many of us accept as normal a state of things which the X rays and the laboratory prove to be highly and dangerously pathological. While admitting, however, that a person whose bowels act only once a day may be less diseased than one who has several daily evacuations, I do not regard "once a day" as the ideal; thrice daily (after meals) should be attained by persons living an active, hygienic life, eating natural "live" food, and adopting the natural squatting posture for defæcation. (THE LANCET, 1923, i., 432.)

I am, Sir, yours faithfully,
ALFRED C. JORDAN.

Upper Wimpole-street, W., Dec. 6th, 1924.

A CASE OF INSULIN POISONING.

To the Editor of THE LANCET.

SIR,—The following case may be of interest to your readers.

Mr. X, aged ?, had been taking 20 units of insulin three times daily for months. He had several times experienced warning symptoms after the midday dose, a feeling of apprehension, weakness, sweating, tremor, and an "all-gone" sensation in the stomach. He had not reported these warnings to his doctor, nor had he ever taken sugar for them. On Nov. 29th he remembers taking this dose as usual at 12 noon, but nothing subsequent to this. At 12.30 he was found by his relatives in a state of coma and sent into this hospital. I saw him at 3.45 P.M. and he was then still comatose; every muscle in the body rigid; feet and legs extended and immovable, like bars of iron; extensor plantar responses in both feet; patellar clonus; pupils neither dilated nor contracted, and responsive to light; breathing very deep and irregular, and a full bounding pulse. The facial expression was most remarkable, being now one of intense effort, now of extreme fear. His arms and trunk were in constant motion, the actions being those of tremendous effort, the movements slow and every muscle standing out.

He was catheterised to exclude the possibility of diabetic coma (I had only a vague history), and then given adrenalin ♏v., and in ten minutes another ♏vii. Improvement commenced immediately after the second dose, the first sign being relaxation of the overacting muscles; the breathing then became quieter, and the expression changed to that of one waking from a strange sleep. Within ten minutes the mind became clear, and he asked where he was. From this point he made an uninterrupted recovery.

The interest of this case seems to lie in (1) the physiological expression of hypoglycæmia simulating the response of the body to some great emergency—e.g., the muscular action, the deep respiration, the full pulse, and the emotional expression. (2) The length of time which a state of hypoglycæmic coma can last, untreated, and recover rapidly and completely—four hours in this case. (3) The action of adrenalin is confirmed. (4) The occurrence of both this and the warning attacks after the midday dose, just when the action of the morning dose is at its maximum (four to six hours). This would tend to show that a twice daily injection is better and safer for patients giving themselves their own injections. (5) The close resemblance of the spasm in this patient to that observed in frogs with experimental insulin poisoning by Huxley and Fulton (*Nature*, Feb. 16th, 1924).—I am, Sir, yours faithfully,

ROBERT V. B. EMMONS, M.B. Oxf.,
Dec. 5th, 1924. House Physician, Radcliffe Infirmary, Oxford.

MEASLES TWICE.

To the Editor of THE LANCET.

SIR,—As in your issue of Nov. 29th you stated that Prof. Johann Loos says that there are no second attacks of measles, I thought that a series of 16 cases of measles which I attended during 1911 might be of interest as each case was, after an interval averaging 16 or 17 days, followed by a second attack. The following case is typical of the series:—

Winifred C., aged 3, was taken ill on April 21st; she had all the catarrhal signs of the invasion stage of measles, and the eruption first became visible on the face on April 24th; this spread over the body and had the appearance of the rash seen in measles. The temperature reached 104° F., and some broncho-pneumonia developed. The condition of the lungs was improving and the temperature was nearly normal when, on May 6th, it rose to 102°; the eyes and nose were running, and on May 9th the rash came out; this was similar to the first rash, it faded in a few days, and the child soon recovered.

All the cases occurred in young children, only three being above 6 years old. None had had a previous attack of measles. Several of the children were examined for Koplk's spots, but there was no definite evidence of these found. None of the second attacks were fatal, but there were several fatal cases of measles in the same district. Of the 16 cases, eight lived in two adjoining streets, and five more lived in a neighbouring district. In one house two children were taken ill about the same time, but only one had a second attack. In another house there were two children; the elder one was taken ill, and ten days after the younger; as this one was recovering, the elder had a second attack, and ten days later the younger one also had a second attack.

During the time these cases were occurring I attended 106 cases of measles. These were in four separate districts. In the first district, 8 out of 54 had a second attack; in the second, 5 out of 30; in the third, 1 out of 4; in the fourth, 2 out of 18. The interval between the attacks varied from 12 to 20 days. This did not appear to be influenced by the complications, as in two cases the second attack developed while broncho-pneumonia was present. Both the primary and secondary attacks were of ordinary severity, except the primary attack in two cases.

I am, Sir, yours faithfully,
Bristol, Dec. 6th, 1924. ERNEST K. GAWN, M.D.

⁂ In his article Prof. Loos was not considering relapse or what he calls "reiteration" in measles, and it is under this heading rather than second attack that Dr. Gawn's interesting cases fall. Such relapse seems to be very rare.—ED. L.

LUPUS ERYTHEMATOSUS AND ALOPECIA AREATA.

To the Editor of THE LANCET.

SIR,—The following case supports the late Dr. M. G. Hannay's interesting observations in THE LANCET of Nov. 29th (p. 1119) on the association of these conditions.

Twenty-five years ago an undergraduate of the athletic type developed alopecia areata. About a year later, in a boxing competition, he received a very slight and superficial abrasion of the skin over the left nasal bone, and also a small bruise over the fourth and fifth metacarpal bones. These were considered trifles and ignored. Suppuration did not occur in the devitalised tissues, but the lesions remained slightly red, painless, and failed to heal. Some months later the unsatisfactory state of the lesions was attributed to neglect and the fact that boxing pursuits had continued. Later still a medical student made the shrewd remark that the condition suggested lupus erythematosus. It was difficult at that time to get this opinion confirmed, but it ultimately proved to be correct. The alopecia areata was active for perhaps a period of three years, and then apparently spontaneously ceased for many years. There has been slight itching of the scalp recently. The face lesions have slowly progressed.

I am, Sir, yours faithfully,
J. HARGREAVES ROBINSON.
Harley-street, W., Dec. 8th, 1924.

SUCTION IN SURGERY.

To the Editor of THE LANCET.

SIR,—Twenty years ago, while working on the problem discussed by Mr. Norman C. Lake in your to-day's issue, I devised the two following instruments.

A sucker for abdominal fluids, consisting of a metal globe, one inch in diameter, with multiple perforations everywhere except at its extreme base. Into the top of the globe ran two parallel metal tubes. One, 9 in. in length, reached only to the top of the globe, its other end being open to the air. The other tube, length 15 in. extended, inside the globe, to just short of the globe's bottom; the outer end of this tube was curved and connected with the suction apparatus. With the globe immersed, either partially or completely, in a pool of fluid, the fluid gravitates, through the perforations, into the bottom of the globe and surrounds the end of the longer tube through which the fluid is sucked out. The shorter tube, by connecting the interior of the globe with the air, prevents the suction from extending to tissues outside the globe.

A combined Junker and evacuator, for cleft palate and allied operations. This consisted of two parallel metal tubes, with curved ends, one for each nostril, the distance between the tubes being adjustable to suit the size of the nose. The anæsthetic tube carried on its inner end a short length of rubber tubing with a terminal opening, which, when in the nose, lay at the level of the posterior nares, the outer end being attached to the tubing of a Junker bottle. The evacuation tube had on its inner end a piece of rubber tubing whose end, having a lateral opening in addition to the terminal opening, lay in the pool of blood and saliva which collects in the nasopharynx of a cleft-palate case when the patient's head is drawn over the end of the table.

These two suckers are described in the *Medical Annual* for 1902.

During operation suckers are useful for removing fluids from cavities and from hollow organs. Their employment for removal of blood from superficial wounds, in my opinion, has little to recommend it. Suction was provided by an ordinary Higginson enema syringe worked by a nurse. The sucking end of the syringe was fitted into six inches of stout rubber tubing, this large tubing being linked up by a tapered metal tube with the six feet of small tubing leading from the sucker. When required a collecting bottle was interposed between the syringe and the end of the tubing attached to the sucker. The reversed enema syringe is very efficient, is available at any time and anywhere, and does away with the need for suction apparatus worked either by water, electricity, or gas bottles.

In my own theatre for 12 years I have used a suction apparatus worked by water, on the principle of that used by dentists. Recently, in a theatre which had no water-suction apparatus, I was glad to revert to the enema syringe, which, during an operation on a ruptured ovarian cyst, evacuated from the pelvis half a gallon of fluid.

I am, Sir, yours faithfully,

Plymouth, Dec. 6th, 1924. C. HAMILTON WHITEFORD.

A WELCOME DISCLAIMER.

To the Editor of THE LANCET.

SIR,—I am very much alive and am going away for a trip to Florida, Cuba, and California, and will put in my time fishing, golfing, &c. I will appreciate it greatly if you will see that THE LANCET corrects the error, as I do not wish to have my many friends in London think I am no more when I am enjoying the most active time of my life.

With very best wishes, I remain,
Sincerely yours,

New York, Nov. 24th, 1924. S. G. GANT.

*** Our review of Prof. Gant's great treatise on Proctology (THE LANCET, Nov. 8th) suggested that its author was dead. Our error is corrected above on good authority and in conclusive terms, we are glad to say.—ED. L.

CHELSEA HOSPITAL FOR WOMEN.—This hospital and its convalescent home at St. Leonards-on-Sea are able to look back upon an excellent year's work. Great progress has been made at the hospital during the past year in the building of its nurses' home and in the completion of the fund for its erection. When the festival dinner was held in May last under the presidency of the then Lord Mayor, the amount of the appeal was £20,000 for the purpose and for the opening of the 47 additional beds. Of this sum there still remains to collect £6500. This is urgently needed so that the home may be opened in the new year free of debt, and also that additional regular income may be forthcoming in view of the great increase which will shortly be possible in the work of the hospital. Some of the additional beds will be devoted to the treatment of those who can no longer, as formerly, afford to pay the fees of nursing homes. The long "waiting list" which has been for many years past a source of much concern to the medical staff will, it is confidently anticipated, soon be eliminated. Contributions are greatly needed, and will be thankfully received by the hon. treasurer or the secretary at Arthur-street, at the Chelsea Hospital for Women.

Medical News.

UNIVERSITY OF CAMBRIDGE: *Diploma in Psychological Medicine.*—A course of instruction covering the material necessary for the psychiatrical portion of the examinations in Part II. of the Diploma in Psychological Medicine will be held in the psychological laboratory of the University and in the Fulbourn Mental Hospital on Tuesdays and Fridays of the Lent Term, 1925, from Jan. 16th to March 10th inclusive. Those wishing to take this course should communicate not later than Dec. 31st next with the secretary, Committee in Psychological Medicine, Psychological Laboratory, Cambridge, from whom further particulars may be obtained.

UNIVERSITY OF LONDON.—At a recent meeting of the Senate the following were constituted the Boards of Examiners acting with the External Examiners for the First and Second Examinations for Medical Degrees in 1925, the examiners whose names are marked with an asterisk being appointed chairmen of their respective boards:—

Inorganic Chemistry: *Mr. J. A. Gardner (St. George's Hosp. Med. Sch. and Lond. Sch. Med. Women) and Prof. C. S. Gibson (Guy's Hosp. Med. Sch.). General Biology: Dr. Doris L. MacKinnon (King's Coll.) and Dr. E. J. Salisbury (Univ. Coll.). Physics: *Mr. J. H. Brinkworth (St. Thomas's Hosp. Med. Sch.) and Mr. B. L. Worsnop (King's Coll.). Organic Chemistry: *Mr. J. A. Gardner (St. George's Hosp. Med. Sch. and Lond. Sch. Med. Women) and Prof. J. C. Drummond (Univ. Coll.). Anatomy: *Prof. E. Barclay-Smith (King's Coll.) and Prof. F. G. Parsons (St. Thomas's Hosp. Med. Sch.). Physiology: *Prof. H. E. Roaf (London Hosp. Med. Coll.) and Prof. Swale Vincent (Middlesex Hosp. Med. Sch.). Pharmacology: Dr. O. F. F. Leyton (Lond. Hosp. Med. Coll.) and Dr. O. Inchley (King's Coll.), and *Prof. A. J. Clark.

The following were appointed Associate Examiners for the M.B., B.S. Examinations in 1925:—

Medicine: Prof. F. R. Fraser, Prof. F. S. Langmead, Prof. H. MacLean, and Dr. Gordon M. Holmes. Surgery: Mr. H. S. Souttar, Mr. C. H. S. Frankau, Mr. E. D. Telford, and Prof. C. A. Pannett. Obstetric Medicine: Mr. M. H. Phillips and Prof. Louise McIlroy. Pathology: Prof. S. MacDonald and Prof. E. H. Kettle.

Dr. Joseph Bamforth was recognised as a teacher of Bacteriology at St. Thomas's Hospital Medical School.—Dr. F. L. Hopwood, D.Sc. Lond., was appointed as from Oct. 1st, 1924, to the University Chair of Physics, tenable at St. Bartholomew's Hospital Medical College.—The title of Reader in the University was conferred on Dr. R. J. Gladstone in respect of the post held by him at King's College.—It was resolved to institute, in accordance with the regulations on University titles, a University Chair of Pathology tenable at the London School of Medicine for Women.

TORONTO UNIVERSITY AWARD.—The Council of the Faculty of Medicine of the University of Toronto have awarded the Charles Mickle Fellowship of the University to Sir James Mackenzie, M.D., LL.D., F.R.S., Honorary Physician to the King in Scotland. The Fellowship, which is of the value of approximately 1500 dollars, is awarded annually to that member of the medical profession who is considered by the Council to have done most during the preceding ten years to advance sound knowledge of a practical kind in medical art or science.

AN EMPIRE FOOD COUNCIL.—A conference will be held in the new year, by consent of the Royal Colonial Institute, in their council room to inaugurate an Empire Food Council, organised to encourage the consumption in the United Kingdom of the food products of the overseas part of the Empire and of Great Britain herself; to spread general information about food; and to arrange a British Empire bread campaign to popularise bread made from wheat grown in Great Britain and the Dominions and ground in Great Britain and Ireland. The chair will be taken by Prof. H. R. Kenwood, supported by Lord Bledisloe, Sir Arthur Crosfield, Sir Harry Baldwin, Sir Arthur Mayo-Robson, Sir Frederick Mott, Major J. Elsdale Molson, Dr. Nathan Raw, and Dr. C. W. Saleeby. Representatives will attend from the Australian Commonwealth (commercial department), the Canadian Chamber of Commerce, the British Empire League, the British Empire Producers' Organisation, the British Empire Union, the Empire Development Union, the Overseas Farmers Coöperative Federations, the Bread and Food Reform League, the Food Education Society, the People's League of Health. Further information can be obtained from Miss May Yates, hon. secretary, Bread and Food Reform League, 37, Essex-street, London, W.C. 2.

Metropolitan Asylums Board.—Courses of instruction for medical graduates and students will be held under the Board from January to March as follows:—

Hospital Administration (for the Diploma in Public Health).—A three months' course of lectures and demonstrations at the North-Western Hospital, Lawn-road, Hampstead, N.W. 3, by Dr. E. W. Goodall, medical superintendent, on Mondays and Thursdays at 4.30 P.M., and alternate Saturdays at 10.30 A.M., beginning Monday, Jan. 5th.

Diagnosis and Treatment of Fevers.—During January next courses will be held at various hospitals under the Board. Dr. F. M. Turner, medical superintendent of the South-Eastern Hospital, Avonley-road, Old Kent-road, S.E., will give a two months' course at that hospital on Tuesdays and Fridays at 11 A.M., beginning Tuesday, Feb. 3rd. Further particulars may be obtained from the Clerk to the Metropolitan Ayslums Board, Victoria Embankment, E.C. 4.

Fellowship of Medicine and Post-Graduate Medical Association.—The Fellowship of Medicine programme of special courses for the month of January includes various specialties as well as a two weeks' intensive course from Jan. 12th to 24th at the London Temperance Hospital. The programme will cover the whole day and will include all the general and special departments of the hospital in addition to a special lecture at 4.30 P.M., to which members of the medical profession are invited. Bethlem Royal Hospital, the Royal Westminster Ophthalmic Hospital, and the North-Western Fever Hospital will be coöperating with the London Temperance Hospital. An intensive course will also be held in cardiology at the National Hospital for Diseases of the Heart from Jan. 12th to 23rd; a series of lecture-demonstrations on the treatment of common nervous diseases will be given at the West End Hospital for Nervous Diseases in the out-patient department, 73, Welbeck-street, W., from Jan. 5th to 31st; a two weeks' course in ophthalmology at the Royal Eye Hospital from Jan. 5th to 17th, comprising clinical cases, followed by a lecture on the more important diseases of the eye; eight lecture-demonstrations in psychological medicine at Bethlem Royal Hospital, and a four weeks' course in urology at St. Peter's Hospital from Jan. 12th to Feb. 7th. Copies of the syllabus of each of the above-mentioned courses, together with the list of special courses arranged up to June, 1925, may be obtained on application to the secretary to the Fellowship of Medicine, 1, Wimpole-street, W. 1. Arrangements are being made for a series of Fellowship lectures to be delivered at the House of the Royal Society of Medicine.

Post-Graduate Entente Between America and England.—The Inter-State Post-Graduate Assembly of America, directed by the State District Medical Association of that country, is visiting the British Islands during the first three weeks of June, 1925, in order to hold the annual congress of the Association, under the presidency of Dr. W. J. Mayo. The itinerary includes, as well as London, Edinburgh and Dublin, Leeds, Liverpool, Manchester, and Newcastle, Belfast and Glasgow. An advisory committee has been formed to organise the reception of the visitors in London, consisting of Sir Humphry Rolleston, Sir William Hale-White, Sir StClair Thomson, and Mr. H. J. Waring, while the arrangements in the provincial cities will be in the hands of Sir Robert Jones, Sir Berkeley Moynihan, Mr. Grey Turner, Sir William Milligan, Sir Harold Stiles, and Sir William Wheeler. Prof. Tuffier will make the preparations for a visit to Paris later. The arrangements of the professional and social programme of the tour has been placed in the hands of Mr. Philip Franklin, who gave a dinner at Claridge's Hotel last week to enable the American Ambassador to meet some of those interested in the movement. The guests included, as well as the advisory committee and the Presidents of the Royal Colleges, the American Consul-General; Lord Desborough, President of the Pilgrims Society; Lord Dawson; Prof. C. M. Gayley, Director of the American University Union in Europe; Mr. Wilson Cross, President of the American Society in London; Mr. F. E. Powell, President of the American Chamber of Commerce; Sir Squire Sprigge, Editor of THE LANCET; Mr. Donald Armour, representing Canada; Dr. R. A. Bolam, Sir D'Arcy Power, Sir Arbuthnot Lane; Mr. Robert Grant, jun., of the American Red Cross; and Dr. Arthur Ellis, Mr. Girling Ball, Mr. H. W. Carson, and Dr. Eric Pritchard, the honorary secretaries of the programme committee. There were no formal speeches on this occasion, but after a welcome from the American Ambassador, Sir Humphry Rolleston and Sir John Bland-Sutton spoke of the interest that would be felt by the Colleges, and Sir StClair Thomson, President of the Royal Society of Medicine, invited the visitors to use two of the lecture rooms in the Society's house during the necessary days—namely, from June 1st to 6th. Other speakers, advocating the practical need of entente, were Mr. Waring, Mr. Powell, Mr. Armour, and Sir Squire Sprigge.

Royal Institution of Great Britain.—The juvenile Christmas lectures will be delivered at 3 P.M. on Dec. 27th and 30th, 1924, and Jan. 1st, 3rd, 6th, and 8th, 1925. They will be given by Mr. Frank Balfour Browne, lecturer on entomology in the University of Cambridge, under the general title Concerning the Habits of Insects. The subject will be divided among the six lectures as follows: (1) Insect Collecting and What It Leads to; (2) Habits of Bees and Wasps; (3) Habits of Caterpillars; (4) Habits of the Dragon-fly; (5) Habits of the Water-beetle; and (6) Habits of Insects and the Work of Man.

Bethlem Royal Hospital.—The spring course of study for the Diploma in Psychological Medicine of the various universities will commence at the hospital on Jan. 5th, 1925. The course consists of lectures and demonstrations in (*a*) the anatomy, histology, and physiology of the nervous system; (*b*) psychology; (*c*) neurology; (*d*) psychological medicine; and (*e*) mental deficiency. A full syllabus of the course, together with a list of the lectures, may be obtained from the physician-superintendent at the hospital, London, S.E. 1.

Presentation to Dr. H. Campbell Thomson.—Following the recent retirement of Dr. H. Campbell Thomson from the staff of the Middlesex Hospital, his colleagues and old fellow students entertained him to dinner at Oddenino's Restaurant on Dec. 3rd. Eighty-nine sat down to dinner, and Dr. Campbell Thomson was presented with a pair of prismatic field glasses, and a George III. silver tankard, on a base suitably inscribed, as a memento of the occasion and a mark of affection and appreciation.

New Children's Hospital for Kensington.—On Dec. 3rd, in the Kensington Town Hall, the Mayor of Kensington, Alderman Archibald Allen, presided over a meeting in support of the proposed Princess Louise Hospital for Children in North Kensington. The hospital is intended to replace the 11 cots at the Children's Hospital in Church-street, and an appeal is being made for £80,000. Lord Balfour of Burleigh, the hon. treasurer of the building fund, stated at the meeting that Princess Louise had intimated her intention of giving £1000, the Mayor of Kensington had subscribed £500, and an anonymous donor through Mr. Percy Gates, M.P., had promised £500 if nine others gave a similar amount each. Sir Henry Seymour King has promised to be one of the nine.

Presentation to Dr. E. W. Hope.—Dr. Hope, who recently retired from the post of medical officer of health for Liverpool after 41 years' service, was on Nov. 25th entertained at luncheon at the Exchange Station Hotel, Liverpool, by the members of the city council, and presented with an illuminated address and a handsome antique silver tray and tankard. Sir Archibald Salvidge presided, and there was a large and representative gathering, including the Lord Mayor and Lady Mayoress. Since his retirement Dr. Hope has been the recipient of expressions of friendship from many of those with whom he has been associated, including his colleagues and staff, the Medical Institution, the Mersey Docks and Harbour Board, the Liverpool Steamship Owners' Association, and the Midwives' and Welfare Associations.

Christie Hospital and Cancer in Manchester.—At the recent annual meeting of the hospital board it was stated that the number of patients treated during the past 12 months was 482, and was a record. Of the 423 new in-patients 125 were inhabitants of Manchester, and the remaining 280 came from many parts of the North of England as far away as Penrith and Newcastle-on-Tyne; 302 suffered from cancers and tumours, and 121 from pre-cancerous conditions or chronic ulcerations. Of the 448 in-patients, 358 had been discharged, 72 had died, and 18 remained in hospital. During the year the hospital had provided a permanent abode for 76 patients who could not properly be treated at home owing to the grave character of their ailment, having been admitted at a late stage of the disease. The chairman of the medical board said that there was a definite increase in the number of apparent cures, and methods of alleviation had increased so considerably that patients could be made fit for treatment at home where formerly they had to be kept in hospital. Fewer patients died to-day from the primary form of cancer owing to the radium, X ray, and operative treatment now available, and the secondary form, which was internal, not external, was, as a rule, not so foul or painful. Prof. R. B. Wild welcomed the interest shown by the public in cancer research. We knew, he said, a great deal more about cancer than about some of the more common diseases. This year the committee had offered a prize of £300 for the best essay on the ætiology of cancer, based on original observations or experimental work. Their object was to find one or more men suitable for carrying on the work of research.

BURY INFIRMARY.—A new children's ward has been added to the Bury Infirmary at a cost for erection and equipment of £12,000 and with an endowment of £30,000. This ward represents the principal of two schemes in the town's war memorial, the other being a cross in the centre of the town. The total sum subscribed was £46,300, of which sum Lord Derby and Lord Stanley jointly gave £5000 and Lord Doverdale, a native of Bury, £4000.

SOCIETY OF APOTHECARIES OF LONDON.—A Livery dinner of the Society was held on Dec. 9th, the Master, Dr. Algernon Brenchley, presiding, supported by the Junior Warden, Dr. Alfred Hepburn, and the Deputy Senior Warden, Mr. Samuel Osborn. The toast of The Combatant Forces, proposed by Mr. Osborn, was responded to by Surgeon Vice-Admiral J. Chambers and Lieut.-General Sir William Leishman; and that of the Royal Colleges and Universities, proposed by the Master, by Sir Humphry Rolleston and Dr. E. Graham Little, M.P. The toast of The Guests was responded to by the Rt. Hon. Sir Henry Craik and Mr. Walter G. Bell, whose literary and archæological interest in the history of London was well displayed in his words. Among those invited were Sir George Makins, Sir George Buchanan, Sir Arbuthnot Lane, Sir Ronald Ross, Dr. de Havilland Hall, Mr. Malcolm Hepburn, and Sir Squire Sprigge. A good musical programme was interspersed with the speeches.

ST. GEORGE'S HOSPITAL: NEW OUT-PATIENT DEPARTMENT.—The new department at St. George's Hospital, London, which has been constructed and equipped at a cost of some £16,000, was formally opened by Sir Humphry Rolleston, the President of the Royal College of Physicians, on Dec. 5th, when he also unveiled a bronze bust of John Hunter which has been mounted over the gateway in Knightsbridge. The bust formerly adorned the board room of the hospital. In opening the new department Sir Humphry Rolleston said that besides providing relief to the sick poor the out-patient department was important as a centre for consultation with general and panel practitioners who could thus obtain an opinion by letter. Some 60 per cent. of the patients were sent to the hospital with that object. The out-patient, also, was in the position to benefit from the highest form of medicine, the ideal of the prevention of disease. Lord Maidstone, the hon. treasurer, referring to the financial struggle which the hospital was making to maintain itself, said that the method of meeting the annual deficit of £20,000 by encroaching on capital could not continue indefinitely. In the new department provision has been made for the different sections—medical, surgical, gynæcological, ophthalmic, and throat, ear, and nose. The buildings are of the most modern type. In the ophthalmic section five special dark-rooms for eye-testing have been made under the road.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Opening of the Session.—The King's Speech.

PARLIAMENT was opened in State by the King on Dec. 9th. In the course of the Speech from the Throne it was stated that a Bill was under consideration for safeguarding employment in efficient industries where, after inquiry, the need for such exceptional action was established. His Majesty's Ministers were deeply impressed by the continued shortage of housing accommodation. Private builders would be encouraged and the Government would devote their attention to overcoming the rising cost of houses and the shortage in the available supplies of labour. New methods of construction would also be encouraged. Something was already being done under existing legislation to clear the worst areas and to remedy sanitary and structural defects in those which remain. As new building increased it would be possible largely to develop this process and the Government would take every opportunity of pressing it forward with vigour. The Government were engaged upon inquiries into the possibility of combining with existing systems of insurance provisions for improved old age pensions and pensions for widowed mothers. Steps would be taken to carry out the principal recommendations of the Committee on the use of preservatives and colouring matter in food, and for the ascertainment of costs and profits in the distribution of milk.

HOUSE OF COMMONS.

TUESDAY, DEC. 9TH.

The Debate on the Address.

IN the course of the debate on the Address in reply to the King's Speech, Lieut.-Colonel FREMANTLE said that the death-rate from tuberculosis had been reduced by one-half in the last 30 or 40 years, and if the other half could be removed, the nation would save £90,000,000 of the national income and about £5,000,000 to the Exchequer annually. A Milk Bill to deal with tuberculous milk was passed at the beginning of the late war, but was never enforced. The time had come when it should be re-enacted.

Referring to the housing question, Colonel Fremantle said the essential thing was to see to the distribution of the houses built. House-building was at present being carried on to a certain extent under town-planning schemes. But town-planning schemes had lagged behind since 1909, when that great ideal was first established. An Act was brought in in 1919 to make the adoption of town-planning schemes compulsory, but the schemes so far referred only to areas that were to be built up. He hoped to see the pace increased and that they would insist that all areas should get town-planning schemes prepared very soon. In addition, they needed new legislation to enable them to complete town-planning by applying it to already built-up areas. All who had had experience in the large municipalities recognised how difficult it was to deal with the large areas where slums were being pulled down, or were to be pulled down with the intention of building up again. There were no powers for town planning in such cases. The need of a Bill to enable town planning to be adopted for areas already built up was urgent. The replacement of old houses should be done on proper lines. The authorities should have power to take over sufficiently large areas and to reconstruct them, not simply to improve streets where they were, but to make a change on a much larger scale. This procedure would have to be brought into relation with the traffic problem, which was only at the beginning of its difficulties. It was owing to the traffic problem that the attention of the public had been directed to the fact that it was necessary to get people out of London. They could not do that with a population congested as it was now. It could be done with improved prosperity and an enormous increase of motor-cars, as in other towns abroad. The two questions must be dealt with together. The problem could be solved only on the principle of the "satellite" city—the principle of the garden city which had already been tried at Letchworth and Welwyn. He hoped that the larger scheme he had suggested might find a part in the Government programme.

There were certain other health services which he hoped that the Government would be able to help. They had been told that a Factories Bill, a consolidating and amending measure, was to be brought in. The Bill introduced in the last Parliament was a very mixed Bill and from the health point of view it was sadly lacking, especially in organisation. It was retrogressive and reactionary in one sense. It took a large measure of local administration out of the hands of the local sanitary authorities and brought it back to Whitehall. It made no arrangement for a proper medical and health department in Whitehall, and it showed no understanding of the necessity of linking up health in the factories with the general health system of the country under the Ministry of Health. Some such system must be devised and carried through in the near future. There were several Ministries of Health now in existence. The Factory Department at the Home Office was almost a Ministry of Health in itself. Health problems under the Board of Education almost demanded a ministry in themselves. The Ministry of Health was the third. There were also large health departments in most of the other Government departments. Yet there was no scheme for linking these things together. It was puerile and absurd to go on in this way. They must have a proper staff arrangement to get them linked up together, with a common policy for working together instead of working as now, in separate compartments.

Other things ripe for solution were being inquired into by Royal Commission or Committee. In the case of the Royal Commission on the Insurance Acts he hoped that the medical profession would make a very great contribution to the inquiry in order to get a national solution of the problem of panel treatment. Then there was the Royal Commission on London Government. He hoped that they would get the problems of London government finally settled, especially with a view to a proper settlement of the health services. Unfortunately, the position of the medical service in India was such that young medical men were being frightened from giving their services to India as so many magnificent men did in the past. What was the attitude of the Government towards the Lee Commission with regard to the medical services in India? If it was proposed to abolish the medical service and to provincialise it the result would be that they would not get men for this essential and humane work in India. The Royal Army Medical Corps was in a most perilous position. Recruits could not be obtained. The same remark applied to the Colonial Medical Services. These questions should be looked at by the Government, not in a piecemeal way, but as part of a definite health policy which would have regard to all the different factors.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Dec. 16th.

GENERAL MEETING OF FELLOWS: at 5.30 P.M.

Wednesday, Dec. 17th.

HISTORY OF MEDICINE: at 5 P.M.
Mr. F. C. Pybus: (1) The Newcastle Barber Surgeons Company; (2) A New Harvey Manuscript in His Own Copy of the "Degeneratione."
Mr. Walter G. Spencer: Exhibit from the Library of 18th Century Anatomical Mezzotints by Jacques Gautier d'Agoty.

Thursday, Dec. 18th.

DERMATOLOGY: at 5 P.M. (Cases at 4 P.M.)
Cases and Specimens:
Dr. Aldo Castellani: Exhibition of Tropical Specimens.
Dr. A. C. Roxburgh: Schamberg's Disease.
Other cases will be shown.

Friday, Dec. 19th.

ELECTRO-THERAPEUTICS: at 8.30 P.M.
A series of short papers and demonstrations will be given by Dr. Friel, Dr. Teall, Dr. Meyrick-Jones, and others.

HUNTERIAN SOCIETY.
Monday, Dec. 15th.—7.30 P.M., Dinner at Simpson's Restaurant, 2 and 3, Bird-in-Hand Court, Cheapside, Discussion on Headache, by Dr. C. O. Hawthorne, Mr. W. Trotter, Dr. Bernard Hart, and Dr. H. Fielding Briggs.

TUBERCULOSIS SOCIETY.
Friday, Dec. 19th.—8 P.M. (at the house of the Society of Medical Officers of Health, 1, Upper Montague-street, Russell-square), Dr. F. G. Chandler: Tuberculous Peritonitis.

CHELSEA CLINICAL SOCIETY.
Tuesday, Dec. 16th.—8.30 P.M. (at the Club Room, St. George's Hospital, entrance in Knightsbridge). A Discussion on Some Diseases Common to Adolescence will be opened by Dr. Theodore Thompson and Mr. Ivor Back.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
Monday, Dec. 15th.—4 P.M., Mr. F. W. Twort (Superintendent of the Brown Institution): Lectures on Modern Bacteriological Technique.
Tuesday.—4 P.M.
Wednesday.—4 P.M.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
Monday, Dec. 15th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards. 2 P.M., Mr. Bishop Harman: Eye Dept.
Tuesday.—11 A.M., Dr. McDougal: Electrical Dept. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.
Wednesday.—12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Dr. Owen: Medical Out-patients. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Dr. Scott Pinchin: Diseases of the Heart. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.
Friday.—10.30 A.M., Dr. Pritchard: Medical Wards. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.
Saturday.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

LONDON HOSPITAL MEDICAL COLLEGE, Turner-street Mile End, E.
Wednesday, Dec. 17th.—4.15 P.M., Sir Arthur Keith: The Clinical Importance of the Bulbus Cordis (Schorstein Memorial Lecture).

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
Tuesday, Dec. 16th.—5 P.M., Dr. Graham Little, M.P.: The Keratoses. General View.

ROYAL DENTAL HOSPITAL OF LONDON POST-GRADUATE LECTURES.
Wednesday, Dec. 17th.—5 P.M., Mr. F. St. J. Steadman: The Technique of Some Surgical Operations about the Mouth.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.
Tuesday, Dec. 16th.—4.15 P.M., Dr. A. E. Barclay: X Ray Treatment of Hyper-thyroidism.
Friday.—Dr. D. E. Core: Early Mental Disease, its Differentiation and Prognosis.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES. (At 3.30 P.M.)
Tuesday, Dec. 16th.—(At the Children's Hospital.) Dr. John Stokes: Rheumatism in Childhood.
Friday.—(At the Royal Infirmary.) Injuries of the Knee-joint, &c.

ST. ANDREWS INSTITUTE FOR CLINICAL RESEARCH.
Tuesday, Dec. 16th.—4 P.M., Dr. Maclennan: Pathology of the Kidney.

Appointments.

Carruthers, A. A., M.B., Ch.B. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the 'Shilton District of Warwick.

Daley, W. A., M.D., B.S. Lond., M.B., Ch.B. Liverp., D.P.H., Medical Officer of Health for the City of Hull.

Higgins, J. B., M.B., Ch.B. Manch., Honorary Radiologist at Buxton Cottage Hospital.

Vacancies.

For further information refer to the advertisement columns.

Adelaide University.—Marks Lectureship in Applied Physiology and Sheridan Fellowship. £750.
All Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, S.W.—Res. Sen. H.S. at rate of £200. Also Jun. H.S. at rate of £100.
Birmingham City Fever Hospital, Lodge-road.—Asst. M.O. £400.
Blackburn and East Lancashire Royal Infirmary.—3rd H.S. £150.
Bradford City.—Sen. Dent. O. £650. Also Asst. Sch. Dentist. £450 and bonus.
Brighton, Poor-law Institution and Infirmary, &c.—M.O. £800.
Bristol Royal Infirmary.—Hon. Reg. to Ear, Nose, and Throat Dept.
Cambridge, Addenbrooke's Hospital.—Cas. O. and Res. Anæsthetist at rate of £130.
Chelsea Hospital for Women, Arthur-street, Chelsea, S.W.—S.
Derbyshire Royal Infirmary.—Hon. Asst. S.
Dumfries and Galloway Royal Infirmary.—Jun. R.M.O. £125.
East Sussex County Mental Hospital, Hellingly, Sussex.—Pathologist. £400.
Edmonton Education Committee.—Asst. Sch. M.O. £600.
Exminster, Devon Mental Hospital.—Jun. A.M.O. £300.
Johannesburg, South African Inst. for Med. Research.—Plague Bacteriologist. £1500.
Malayan Medical Service.—Medical and Health Officers. See advt. for salaries.
Manchester Royal Infirmary.—2nd Surg. Reg. £150.
Merthyr General Hospital, Merthyr Tydfil.—Res. H.S. at rate of £100.
Preston Royal Infirmary.—Jun. H.S. £175.
Queen Mary's Hospital, Stratford, E.—Hon. Asst. P. Also Clin. Asst. to Throat, Nose, and Ear Dept.
Royal Army Medical Corps.—Commissions.
Royal Masonic Institution for Girls, Clapham Junction.—M.O. £350.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Cas. O. £150.
St. Bartholomew's Hospital.—Assts. to the Surg. and Med. Professional Units.
St. Mary's Hospital, W.—Med. Reg. £200. Med. Supt. £400.
St. Pancras Dispensary, 39, Oakley-square, N.W.—Hon. P. and Hon. Ophth. S.
Southampton County Borough.—2nd School Dentist. £450.
Southampton, Royal South Hants and Southampton Hospital.—Sen. H.S. £200.
South Shields, Ingham Infirmary.—Sen. H.S. £200.
Stroud General Hospital.—H.S. £120 to £150.
Weir Hospital, Grove-road, Balham, S.W.—Hon. Visiting Phys.
West Bromwich and District Hospital.—Res. Asst. H.S. £180.
West Ham County Borough.—Tuberculosis O. £900.
West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S. and Res. Cas. O. Each at rate of £100.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Portishead, Somerset, and Ellesmere Port, Cheshire.

Births, Marriages, and Deaths.

BIRTHS.

Woodroffe.—On Dec. 5th, at "Oakvale," Sheffield, the wife of Dr. G. C. L. Woodroffe, of a son.

MARRIAGES.

McCarthy—Bone.—On Dec. 5th, at St. Hilary's Church, Llanrhos, Llandudno, Herbert John McCarthy, M.R.C.S., L.R.C.P., to Cicely Bessie, youngest daughter of Mr. and Mrs. Ernest E. Bone, Rocknest, Llandudno.

DEATHS.

Compston.—On Dec. 2nd, at Ashley-gardens, S.W., after a long and painful illness (contracted on war service in Mesopotamia), Captain George Dean Compston, B.A. Camb., M.R.C.S., L.R.C.P.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE PRESENT POSITION OF INSULIN THERAPY.*

BY GEORGE GRAHAM, M.D., F.R.C.P.LOND.,
ASSISTANT PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL;
PHYSICIAN, ROYAL NORTHERN HOSPITAL.

IN opening a discussion on the present position of the treatment of diabetes with insulin it is unnecessary to speak in detail about some aspects which had to be considered a year ago, and I would rather discuss the principles which are controlling its use. Everyone will agree that while insulin is invaluable in the treatment of diabetes it cannot be called a cure. The points which I would like to consider are these :—(1) The aims of treatment with insulin. (2) The type of case which should be treated with insulin. (3) The best type of diet. (4) The value of insulin in the treatment of coma. (5) The value of insulin in the treatment of other infections and minor complications.

The Aims of Treatment.

One of the chief difficulties in deciding these points is the improvement which takes place in the clinical condition of the patients on all varieties of treatment with insulin. The patients nearly always feel so much better that it is difficult to say which is the correct line of treatment, and another five years may have to pass before some of these questions can be answered with certainty. Before the introduction of insulin it was accepted that the patient's diet should be so adjusted that the urine did not contain any sugar, and that the fasting value of the blood-sugar was within the normal limits of 0·08 to 0·12 or 0·13 per cent. In order to achieve this it was necessary in severe cases to give a diet of very low caloric value, and the patients were all much under the normal weight. When insulin was available the natural thought of most workers was that the patient need no longer be undernourished. The carbohydrate was increased so that at some time of the day the blood-sugar was raised above the normal level and sugar was excreted in the urine. Of the eight groups of workers in Canada and the United States who took part in the early study of insulin only two, the Toronto school (Banting, Campbell, and Fletcher) and Allen's school, aimed at keeping the fasting value of the blood-sugar within normal limits; one, Joslin, tried to keep the urine sugar-free; but the other five all thought that it was unnecessary to keep the urine sugar-free at all hours of the day. In this country the early workers, Poulton, Spriggs, and myself, urged that the ideal of treatment was to keep the urine sugar-free and the level of the blood-sugar within the normal limits 0·08 and 0·13 per cent. This attitude was taken from the consideration of the hypothesis that diabetes is due to a degeneration or hydrops of the beta cells of the islands of Langerhans, and that it is essential that the surviving beta cells should not be overworked at any hour of the day or night. The evidence of overwork would be either the presence of sugar in the urine or a blood-sugar above the fasting value of 0·13 per cent. I think that it is now generally admitted that this practice is correct since it is physiological, although it is not always easy to carry out. So far I have encountered only one patient in whom it proved impossible to maintain the fasting blood-sugar within normal limits some 12 hours after the last dose of insulin.

Another ideal in treatment is that the urine should not contain any acetone bodies. In order to attain this there must be a correct balance between the ketogenic and antiketogenic substances in the diet. This is an ideal which I have not aimed at. I have been content provided that the nitroprusside test for aceto-acetic acid in the urine has not been intense. The usual amount of aceto-acetic acid which patients who are doing well excrete is about 1 g. calculated as acetone. There is one practical advantage in allowing a little ketosis, since if the urine contains no aceto-acetic acid the patient has certainly been adding some carbohydrate to the diet. Although I am not convinced that this small amount of ketosis does any harm, I will admit that it is wrong on physiological grounds, and that it would be better to increase the carbohydrate ration by 5 or 10 g. in order to prevent this ketosis.

The ideal before the discovery of insulin was that the patient should be definitely under weight. I still think that this is the right aim, but that it is sufficient if the patient is about 5 per cent. below the normal weight instead of the 15 to 20 per cent. which was common before. Further, the weight curve should be the guide to the total caloric value of the diet and should determine whether it should be increased or decreased. In children there should be a slow increase. This is necessary as the children have to grow, but they should never be allowed to become fat, and should always be underweight.

Indications for Insulin Therapy.

When insulin was first introduced it was said that if patients could take a reasonable amount of food, say 50 g. of carbohydrate and an adequate caloric value, without passing sugar, it was unnecessary to give them insulin. This view is still held by some, but I have never accepted it. The improvement which occurs in the clinical condition after a small dose of insulin, 5, 10, or 15 units, is very striking. The patient gains weight and feels capable of doing work, even if no change is made in the diet. This is also Joslin's view, and it would seem as if insulin helped with some other process besides the sugar metabolism, although there is no other proof of this at present.

Insulin has been used in the treatment of the young adult who has had an acute attack of the disease and has come under observation a short while after the onset of symptoms. The sad experience of these cases before the introduction of insulin was that this type of patient responded well to dietetic treatment, but after one to two years began to lose tolerance in spite of all restrictions. The average duration of life of this type of patient for the age-period 20 to 40 was only 5·3 years (Joslin). It therefore seemed justifiable to treat these patients with insulin early in the disease in order to try to prevent the fall in sugar tolerance and perhaps cause a definite rise in sugar tolerance. If small amounts of carbohydrate are given together with sufficient insulin to deal with this sugar the work of the beta cells will be reduced to a minimum. I have been watching six patients and testing the sugar tolerance at intervals by means of a dose of sugar. The actual amount of carbohydrate varies, as four patients are taking 16 to 20 g., one 30 g., and one 60 g. The dose of insulin also varies from 8 to 15 units. It is usually given in one dose, but two patients take it in two doses.

The blood-sugar curves after a dose of 50 g. show that the change in tolerance which has taken place has been very slight, but what change there is, is in favour of an improvement. It is too early to say much about these patients as it will be another four years before they reach the average of their class. Still it may prove a hopeful line of research.

The Best Type of Diet.

The next important question is the nature of the diet which should be used. Everyone acknowledges that the composition of the diet is just as important as before the introduction of insulin, and in fact more attention is paid to it. There is little dispute over the amount of protein, and the usual amount varies from 2/3 g. to 1 g. per kilo of body-weight. But the amount of carbohydrate varies from 16 or 20 g. to 50, 80, 100, or even 200 g. for the same type of case. The dose of insulin varies enormously under these conditions. For more than three years I have felt that a patient who had a definite attack of true diabetes should never take more than a minimal amount of carbohydrate in order to lighten as much as possible the work of the beta cells of the islands of Langerhans. Such a patient has probably lost at least half and perhaps three-quarters of the beta cells (judging by Allen's dog experiments), and has lost the greater part of his reserve power for dealing with carbohydrates. Till now I have usually restricted the carbohydrate to 16 or 20 g. of sugar in the form of vegetables or fruit, but I think that the better figure may be 25 to 30 g. The objection to giving amounts like 50 or 80 g. of carbohydrate are these: (1) The dose of insulin must be larger and the time chosen for the injection must bear a definite relation to the carbohydrate meal. Opinions differ as to the best time to give the injection, some favouring 30 minutes and others 60 minutes. Having to take the insulin a definite time before the meal makes the use of insulin still more of a nuisance. If the amount of carbohydrate is restricted to a minimum there is no need to be so careful about the time of the injection. (2) The relation of the insulin is not quite constant, but varies a little at times. Sometimes the patient may pass a little sugar and at other times he may be in danger of hypoglycæmia on a dose of insulin which is usually quite adequate. (3) Whether it is more of a temptation to the patient to add carbohydrate to the diet if he is taking some bread than when he takes none at all is arguable. I have the feeling that it is better for the patient to forget the taste of bread altogether than to be exposed to the temptation when he takes a fraction. It may prove easier to take none at all of a pleasing food or drink than to take an unsatisfactory amount of it. Another danger of the high carbohydrate feeding arises from the large amount of insulin which is necessary. Should the insulin be stopped for any cause there is an immediate danger of coma in severe cases unless the food is at once reduced. Opinion is also divided on what should be the caloric value of the diet. This varies from 22 to 30 calories per kilo. This for a man of 10 st. 3 lb., or 65 kilos, would be 1400 to 2000 calories. I favour the low values as I have found that with them patients maintain their weight quite satisfactorily. One disadvantage of the high caloric diet is the necessity for an extra amount of fat which must be given to make up the caloric value, and this demands an extra amount of carbohydrate to prevent ketosis.

---

* A paper, slightly abridged, opening a discussion on the Present Position of the Treatment of Diabetes by Insulin, read at the Medical Society of London on Dec. 8th.

Effects of Insulin on Coma.

I have no space to say much about coma, though it is in this condition that the value of insulin is most striking. The dose must often be large, 100 units or more in the day, and it is wise to give at least 50 g. of sugar with it. It is advisable to make one or more estimations of the blood-sugar and to examine the urine every two or three hours, so as to avoid the danger of an overdose. The observation of patients in coma has shown that often some acute infection has occurred. Of nine cases at St. Bartholomew's Hospital in one year there was conclusive evidence in seven of such a complication—e.g., otitis media and gangrene of the lung. It follows that whenever a diabetic patient is found in coma a complete examination must be made, and repeated if necessary to exclude this possibility.

Insulin and Concurrent Disease.

The whole question of the effect of other diseases on the diabetic condition is of far-reaching importance. It is a common experience to find that the sugar tolerance is impaired by trivial ailments like colds in the head or an attack of diarrhœa, especially in children. Under these circumstances all these affections should be treated seriously, and the patient should be kept under close observation. The dose of insulin should be increased, and if it be possible, estimations of the blood-sugar should be made so as to ensure that the dose of insulin is adequate. If insulin is used to control the evil effects of the concurrent disease, and thus prevent the overwork of the beta cells which occurs when the blood-sugar is raised for long periods, it should prevent the fall of sugar tolerance.

In conclusion, insulin has enabled the patient to live longer and to enjoy this longer life. It will almost invariably resuscitate the comatose patient. The outstanding problem is the study of the means by which it may be used to prevent the progress of the disease.

A DISCLAIMER.

Dr. V. S. Hodson has brought to our notice that in a recently published book personal reference has been made to him, and his professional address has been added in a footnote. At the suggestion of the Registrar of the General Medical Council, Dr. Hodson desires to state in our columns that he had no knowledge that such information would be given, nor had he any idea that reference would be made to him in any shape or form.

MALARIA AND MOSQUITOES IN AUSTRALIA.

AT the close of the nineteenth century, when mosquitoes were first proved to be of great economic importance, very little was known concerning the habits of even the commonest species. At first very little attention was given to the aquatic stages of the insect, and the adult insects only were named with the inevitable redundancy of nomenclature, for since 1910 many species previously named have been found invalid. The second decade of this century has been a period of revision, a list of useless synonyms has been unravelled, numerous genera have been rearranged and included in one comprehensive genus, so that, at the present time, most of the systematic study of mosquitoes is concerned with synonyms. These circumstances have given rise to the preparation by Mr. L. E. Cooling of a handy list[1] of the principal *Culicidæ* of the Australian region.

He has also published an account of the larval stages and biology of the commoner species of Australian mosquitoes with the biology of *Aëdes perniciosus*, Edwards,[2] which, in conjunction with the work mentioned above, completes the record of information on Australian mosquitoes up to date. A more careful account of the morphology, breeding places, and habits of these insects could hardly be conceived. Further, Mr. Cooling has contributed a valuable appendix on the anopheline mosquitoes of North Australia and its tropical dependencies to a publication in the same series.

A third of Australia lies within the tropical zone, with the addition of Papua and the Mandated Territory of New Guinea. Before the advent of the white man tropical Australia was probably malaria-free, but it has since become infected. The endemicity of the disease, save in a few scattered areas, has not been of grave extent, but it is otherwise in Papua and New Guinea. In the space of 141 pages Dr. C. W. Cilento[3] has presented a concise and readable account of the ætiology of malaria, its clinical manifestations, diagnosis, and preventive measures written from the viewpoint of an Australian. All these pamphlets reflect credit on the institute, and are an index of the useful work being performed there.

THE ANTISEPTIC VALUE OF TOOTH PASTES.

THE literature of tooth pastes is as abundant as it is enthusiastic, but it is not always so accurate as it should be. It is claimed for many well-known tooth pastes, in no uncertain terms, that they possess powerful germicidal properties. These claims have been put to the test by two chemists, Mr. A. E. Parkes and Mr. A. E. Maddy (*Pharmaceutical Journal*, Nov. 8th, p. 563), who examined 12 of the best known brands of English and American make. The pastes were investigated for their antiseptic properties and the results were to show that in practically all cases the claims made by the makers are grossly exaggerated. Four of the samples had no antiseptic properties ; even when the common germs of the mouth were left in contact with a mixture containing 25 per cent. of the tooth pastes for half an hour the organisms were not destroyed. It took from 15 minutes to half an hour for a 10 per cent. solution of the other eight samples to destroy the test organisms. As tooth paste usually remains in contact with the teeth for a few seconds only, it seems clear that the paste even in an undiluted state can have little, if any, effect upon the germs of the mouth. Manufacturers of disinfectants almost invariably sell their goods with a guarantee of germicidal strength compared with carbolic acid. The investigators suggest that manufacturers who recommend their tooth pastes for purposes other than cleaning the teeth should produce evidence of the value of their goods as disinfectants. The spread of disease might be encouraged by literature making claims for tooth pastes which give a feeling of false security to those who use them.

CZECHO-SLOVAKIAN ORNAMENT.[4]

THE employment of men injured in the war as broderers has become fairly common, and we have received a small portfolio, containing 45 original plates, comprising several hundreds of patterns from the entire territory of Czecho-Slovakia. They are in colours and in black and white, and many of them are very beautiful. The aim of the publication is to assert the claims of the Czecho-Slovakian races to these designs, and in a way, no doubt, these claims are just. Many of the motives are to be found in Persian, Turcoman, Egyptian, Cretan, and other Mediterranean embroideries and ceramics, but as employed in Bohemia and the adjoining provinces, where they have been modified and transmuted through many centuries, they emerge as characteristics of the countries and peoples now forming Czecho-Slovakia. For this reason it is to be regretted that the method of production of these plates should be so distinctly Viennese. Their coarseness of presentation is a real drawback, and we should have been able to recommend them as practically useful more easily had photogravure or some similar process been employed, whereby the details of actual use and treatment could have been studied. The charm of a design may depend entirely on its treatment. The Mediterranean countries possess many motives in common, and it is only the details of treatment which betray the nationality of the worker. Among these plates No. 27 shows a design so Persian in origin that far more detail of treatment is necessary before its claim to be a European pattern at all could be substantiated. How Spanish, too, is plate No. 44 ; but this probably can be explained by the tremendous Spanish influence exercised for so long in the Netherlands.

Schorstein Lecture

ON THE

FATE OF THE BULBUS CORDIS IN THE HUMAN HEART.

Given at the London Hospital Medical College on Dec. 17th, 1924,

BY SIR ARTHUR KEITH, F.R.S.,
CONSERVATOR OF THE HUNTERIAN MUSEUM.

ON an autumn afternoon, now 20 years distant, I was studying in the Museum of this College the series of specimens which illustrate the various kinds of malformation to which the human heart is liable when I was joined by Dr. Schorstein—that beloved and still youthful physician whose memory we recall to-day. I remember discussing with him the cause of congenital malformations of the heart, and I have chosen the problems of the *bulbus cordis* as the subject of this lecture partly because of Dr. Schorstein's interest in congenital disorders of the heart and partly for another reason. The evidence I had collected—for I searched the medical museums of London and brought together notes on 185 specimens—was sufficient to show me even then that in the vast majority of cases of congenital heart, the defect is due to an imperfect incorporation of the bulbus element. This contention, I think, is now admitted as far as abnormal hearts are concerned, but I do not think that either clinicians or physiologists have yet fully perceived the bearings which this theory has on the constitution and action of the normal heart. It is for this reason that I propose to discuss the fate of the *bulbus cordis* in the human heart. My aim will be to demonstrate the parts of the ventricles formed out of this element, and to show reason why separate consideration must be given to these parts in all our attempts to unravel the exact mechanism of the ventricular pump.

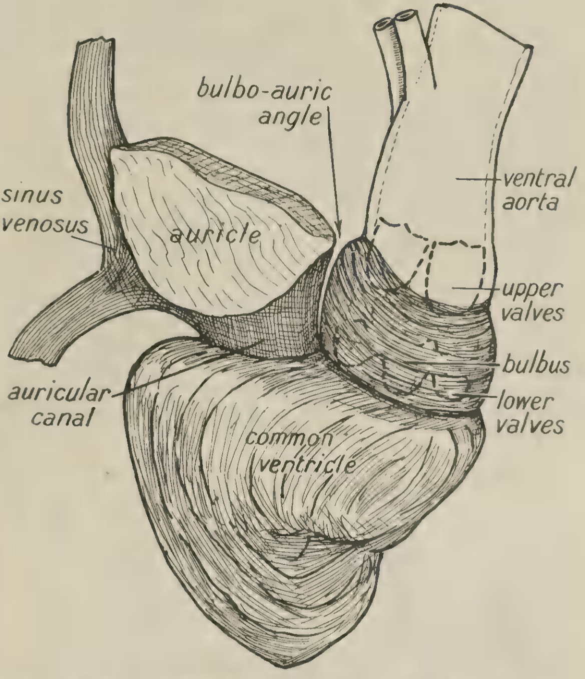
A CURIOUS SPECIMEN OF A MALFORMED HEART.

There was one specimen catalogued amongst the malformed human hearts in the London Hospital Museum which both puzzled and astonished me. In Fig. 1 I reproduce a drawing of this specimen made some 20 years ago. The history in the catalogue ascribed this heart to a child which had lived some months. It was easy to recognise in it all the parts of the selachian or shark's heart—namely, the sinus venosus, the common auricle, the auricular canal, the common ventricle, and the *bulbus cordis* with its lower and upper valves. The embryological investigations of Francis Balfour had given us every reason to believe that the heart of the developing dog-fish represents an ancestral stage in the evolution of the mammalian heart. I was therefore not at all surprised to find a human heart which, in the arrangement of its parts, mimicked so closely that to be seen in the heart of a shark. Fortunately for me, I did not find out until three years later that a mistake must have been made as regards the history of this specimen. For I ultimately proved it to be the heart, not of a child, but of a shark. Some former curator must have mounted it for comparison with malformed human hearts, and during remounting of specimens it had been placed in the wrong jar—one to which there was attached the history of a human heart.

I have said that it was fortunate that I did not perceive my mistake at first, for it was a comparison of this specimen with others in the series of malformed hearts which led me to see that in the course of evolution the *bulbus cordis* must have become incorporated in the ventricles of the human heart. In the series there were specimens showing such a condition as is represented in Fig. 2, where a chamber below the orifice of the pulmonary artery is demarcated from the rest of the right ventricle. Then there were specimens, such as is shown in Fig. 3, where a shallow chamber at the opening of the aorta is separated from the rest of the left ventricle by a constricting ring. I found that the condition in the one kind of specimen was described as pulmonary stenosis, in the other as subaortic stenosis.

Now it seemed clear to me that there was only one way of accounting for these abnormal chambers at the commencement of the aortic stems: they could only be explained by supposing that the *bulbus cordis* did become incorporated in the ventricles and that in these abnormal instances its amalgamation had been arrested. They occupied the exact sites at which the bulbus should appear. A consideration of these specimens also made it clear that the bulbus, like the ventricle, had undergone a division into right and left parts, but that while the part thrown into the left ventricle normally disappeared it was otherwise with the right division; it formed a very large and, from a functional point of view, a very important part of the right ventricle—a part which we shall have to examine presently.

FIG. 1.



To show the various parts of the primitive vertebrate heart.

INCORPORATION OF THE BULBUS ELEMENT IN THE VENTRICLES.

Having satisfied myself on these points I then turned to see how far embryological evidence favoured my theory. I found that Dr. A. Greil, of Vienna, had published in the previous year[1] a splendid research on the development of the heart of reptiles in which he demonstrated that the *bulbus cordis*, while a separate chamber at an early stage, becomes at a later stage overwhelmed by the musculature of the ventricles, and is thus not obliterated but incorporated as an intrinsic part of the ventricular system. It was manifest from what I had observed in these abnormal hearts, that the same thing occurred in mammalian hearts.

Early in February, 1905, there was a meeting of the Anatomical Society at the London Hospital, at which I showed the abnormal hearts just mentioned and made a communication[2] which was published in the

[1] Morph. Jahrb., 1903, Bd. xxxi., p. 123.

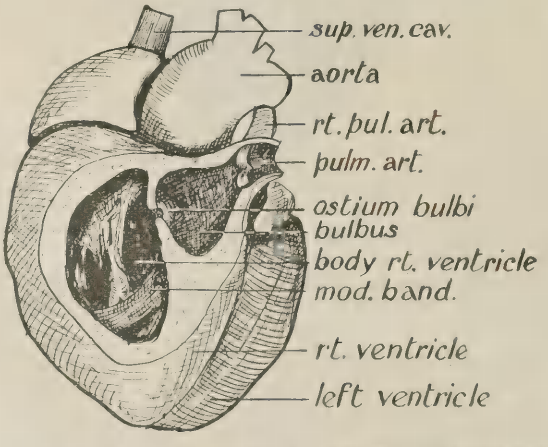
[2] Proc. of the Anat. Soc. of Great Britain and Ireland, February, 1905; included in the Jour. of Anat., 1905, xix., 14.

Proceedings of the Society. As this paper has escaped the notice of clinicians, I have reproduced the simple diagrams with which my early paper was illustrated. In Fig. 4, the right ventricle of a normal human heart has been thrown open and from the septal wall of the infundibulum are seen to arise two great muscular bands, the left infundibular (A) and the right (B). The raphe at which the origins of these two bands meet will be seen to correspond with the origin of the aorta from the left ventricle. The position of the interventricular orifice is indicated by a black dot, just above E. On the sides of the ventricle two points are marked *x*, *x*; these points I originally regarded as indicating the limits of the fully expanded infundibular or bulbus cavity.

In Fig. 7 a more marked arrest in the expansion of the infundibular cavity is depicted; it will be seen that the interventricular foramen remains open, this opening always lying below the level of the bulbus element. In Fig. 8 the arrest of expansion of the bulbus element is almost complete; it is represented merely by a narrow channel lined with thickened endocardial tissue. The interventricular foramen in such specimens is widely open. Then in Fig. 9 is shown a rarer condition, one in which the infundibular element forms a separate cavity and opens from a ventricle in which the septum is absent or imperfectly formed. In this series we see all stages of arrest in the expansion and incorporation of the bulbar element in the ventricles. In subsequent papers I extended the scope of my evidence and sought for a rational explanation of transposition of the great arterial stems.[3]

Since these original papers were published investigations carried out by the late Prof. Franklin Mall,[4] by Prof. J. E. S. Frazer,[5] by Prof. David Waterston,[6] and many others have revealed the exact manner in which the bulbus becomes incorporated in the ventricles during the development of the human heart. In the meanwhile, too, my own knowledge has been extended in three directions. I have come to see that the developing endocardial tissue of the primitive auricular canal and of the bulbus—tissue out of which valvular structures are fashioned—is endowed with most remarkable formative qualities. It behaves, in the development of the heart, exactly as does the granulation tissue of a healing wound.[7]

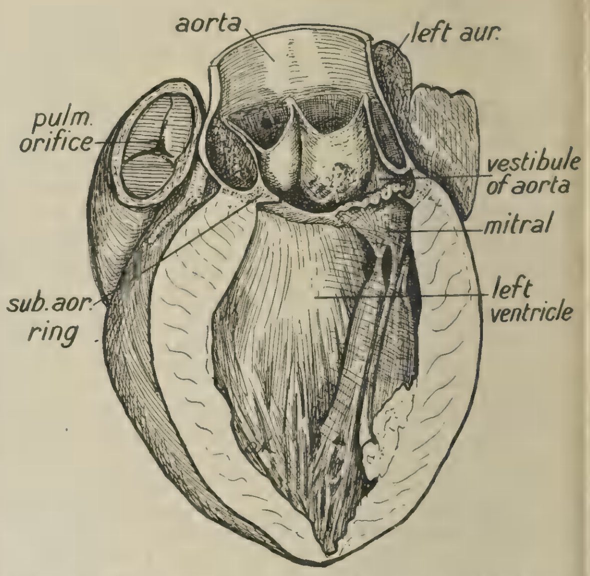
Fig. 2.



Heart of a child, aged 8 months, in which the right ventricle is laid open to show the imperfect incorporation of the infundibular or bulbus element.

In the second place, I have come to see that the muscle cells of the developing heart have a power of invasion, of spreading into and occupying endocardial tissue-masses and of grouping themselves into elaborate formations beyond anything one had formerly conceived as possible. One has for long been familiar with the origin of the complex musculature of the face; it arises in the neck and, from a localised origin, creeps out to occupy the subcutaneous tissues of both face and scalp. We must ascribe to the muscle cells of the developing heart an equally great power to undergo collective migration and to rearrange themselves in orderly but complex formations. In the third place, I have been able to satisfy myself that the *bulbus cordis*, however much it may change in form and in position in the various kinds of vertebrate heart, retains essentially the same function throughout its history.

Fig. 3.



Heart of a man, aged 20, in which the left ventricle is laid open to show a constricting ring below the orifice of the aorta. This ring separates the vestibule of the aorta from the rest of the left ventricle.

Functional Significance of the Bulbus Cordis.

To understand the functional significance of the *bulbus cordis*, one has to keep in mind that the vertebrate heart was originally a gill-pump. The bulbus is interposed between the gills and the ventricular pump as a safety mechanism. A respiratory network of vessels, whether it be spread out on gills or disposed on the walls of air chambers, is a delicate and weakly-supported structure, ill-designed to withstand sudden increases of ventricular output. No doubt, between the strokes of the ventricular pump, the musculature of the bulbus chamber maintains a steady flow of blood through the gills, but its main purpose seems to be that of a shock-absorber—a safety mechanism which prevents the ventricular pump, in states of extreme exertion, from damaging the respiratory network of vessels.

Medical men are apt to look on the heart as a systemic pump—as a pump for maintaining a head of pressure in the arteries of the body. Although this is rightly reckoned the chief action of the heart, it is really a secondary and recent function which came about when gills began to be displaced by lungs.[8] The main changes which have transformed the heart of the fish into that of the mammal are those connected with the evolution of an effective pump for the arterial system of the body. These changes ended in a complete obliteration of that part of the bulbus which intervened between the left ventricle and systemic aorta. By the obliteration of this part of the bulb it became possible for the ventricular musculature to lay direct hold of the commencement of the aorta, and to pump the blood directly into the arterial system.

---

[3] My subsequent papers will be found in the following publications: Malformations of the Bulbus Cordis. Studies in Pathology. Edited by Prof. William Bulloch (Aberdeen, 1906). Malformations of the Heart, The Lancet, August 7th, 14th, 21st, 1909. Specimens of Abnormal Heart, Jour. of Anat., 1912, xlvi., 211. Very important contributions to our knowledge of bulbus abnormalities have been made in more recent years by Dr. Alexander Spitzer of Vienna (Ueber den Bauplan des normalen und missbildeten Herzens, Virchow's Archiv, 1923, Bd. ccxliii., 81–272) and by Dr. Jane Robertson (Comparative Anatomy of the *Bulbus Cordis*, with special reference to Abnormal Position of the Great Vessels, Jour. of Path., 1913, xviii., pp. 191–210, 211–217).

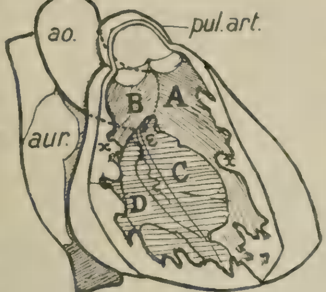
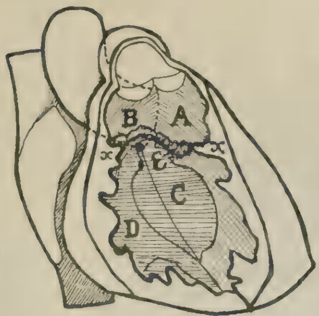
FIG. 4.



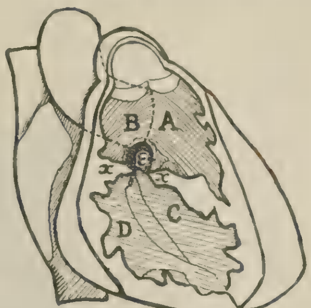
The right ventricle of the normal human heart, laid open. A, left infundibular band. B, right infundibular band. C, body of right ventricular cavity. D, on the tricuspid valve. *x*, *x*, limits of the infundibular or bulbus cavity.

FIG. 5.



A condition in which the infundibular cavity is imperfectly expanded, its orifice being surrounded by thickened endocardial tissue. Letters as before.

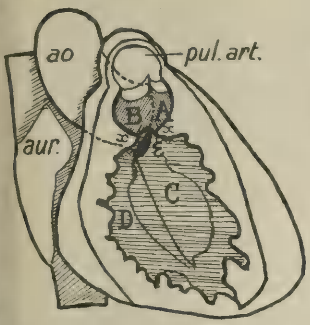
FIG. 6.



A stage in which the arrest of the infundibular expansion is less marked than in Fig. 5, but the orifice is still marked by a margin of thickened endocardium. The interventricular orifice is seen to lie below the infundibular orifice of the fully expanded infundibular or bulbus cavity.

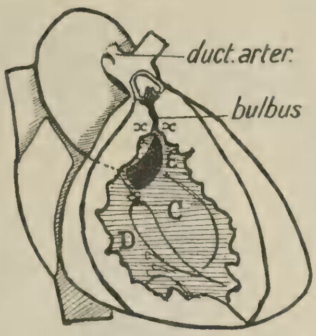
In the evolution of the mammalian right ventricle parts of the old heart were transformed and utilised. In Fig. 10 are shown the three elements out of which the respiratory blood pump has been compounded. There is in the first place the body of the right ventricle—that part in which the tricuspid valve lies. It represents a highly modified part of the old common ventricle. There is, in the second place, the infundibular cavity—that part of the ventricle which lies above the level of the tricuspid orifice and the moderator band. This element is derived from the ancient bulbus—that part which intervened between the common ventricle and the pulmonary aorta. The bulbar cavity, although merged in the right ventricle and overwhelmed by ventricular musculature, still serves, as the original bulbus did, as a safety mechanism for the vascular network of the lungs.[9] Then, in the right ventricle, there is a third or apical element. This is the last part of the right ventricle to appear in the course of evolution and development, and is formed by a delamination of the outer muscular coat from the central core of the main or left ventricle. The right ventricle is but a side-pocket on the wall of the left ventricle.

FIG. 7.



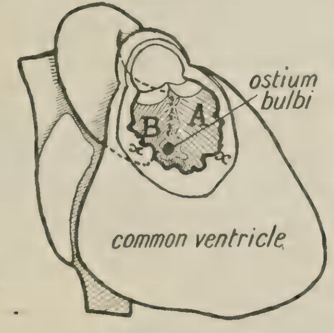
A stage in which the infundibular cavity remains as a small endocardially lined chamber—the commonest of all forms of cardiac abnormality. Letters as before.

FIG. 8.



A stage in which the infundibular cavity (or bulbus element) remains as a narrow channel with thickened lining.

FIG. 9.



Condition in which the infundibular element remains as a separate cavity. It opens from a common ventricle—one in which the interventricular septum is absent or imperfectly formed.

Anatomy of Infundibular Cavity of Right Ventricle.

Having thus outlined the history of the bulb of the ancient heart and shown that all that now remains of it in the human organ is the infundibular cavity of the right ventricle, I now turn to the anatomy of this neglected, but as I suppose, important part of the heart. In Fig. 11 is shown the right aspect of a human heart, in which the ventricles are in a state of contraction or systole. The epicardium has been dissected away to show the arrangement of the muscular fibres, the auriculo-ventricular canal of the right side, and the origin of the aorta. The root of the aorta is seen to dip down behind the infundibulum (B) and to become fused with the canal of the right auricle. Behind, it becomes fused with the canal of the left auricle. In these junctional regions all traces of both bulbus and ventricle have been obliterated, the aorta coming into direct union with original parts of the common auricular canal. It is otherwise at the commencement of the pulmonary artery; here we find the infundibular part of the right ventricle masking the origin of the aorta. Its outer fibres are arranged as a series of horse-shoe loops, which encircle the infundibulum. These loops will be seen, as the infundibulum is traced downwards, to cease abruptly above the point marked D in Fig. 11, but when traced along the auricular margin of the infundibulum (Fig. 11, C), they merge with the spiral fibres which arise from the base of the right ventricle. This is because the bulbus element, as it expands, always extends to the base of the right ventricle, in front of the tricuspid orifice. Thus we have on the right side of the heart a special muscular chamber interposed between the pulmonary aorta and the right auricular canal. This is the persistent part of the original *bulbus cordis*, which, as we have seen, becomes obliterated on the left side of the heart.

---

[8] This matter has been ably discussed by Dr. Alex. Spitzer, Ueber die Ursache der Zweiteilung des Wirbeltierherzens, Archiv für Entwicklungsmech, Bd. xlv., p. 686, 1921, Bd. xlvii., p. 512.

[9] It was my intention to follow out the history of the *bulbus cordis* in the Dipnoi (mudfishes), Amphibia, and Reptilia, and show that in all of them this element of the heart retains its original function—namely, the safeguarding of the capillary system of the lungs from high and prolonged accessions of blood pressure. To have done so would have taken me too far afield. In the Dipnoi and Amphibia the bulbus still lies above and separate from the ventricles; in Reptilia it becomes submerged in the ventricles and surrounded by ventricular musculature. It is quite true that in all of these vertebrate types the bulb has become a mechanism for directing the venous blood to the lungs, but it is able to perform this function just because of its original purpose—namely, its power of preventing high pressures passing into the pulmonary arteries.

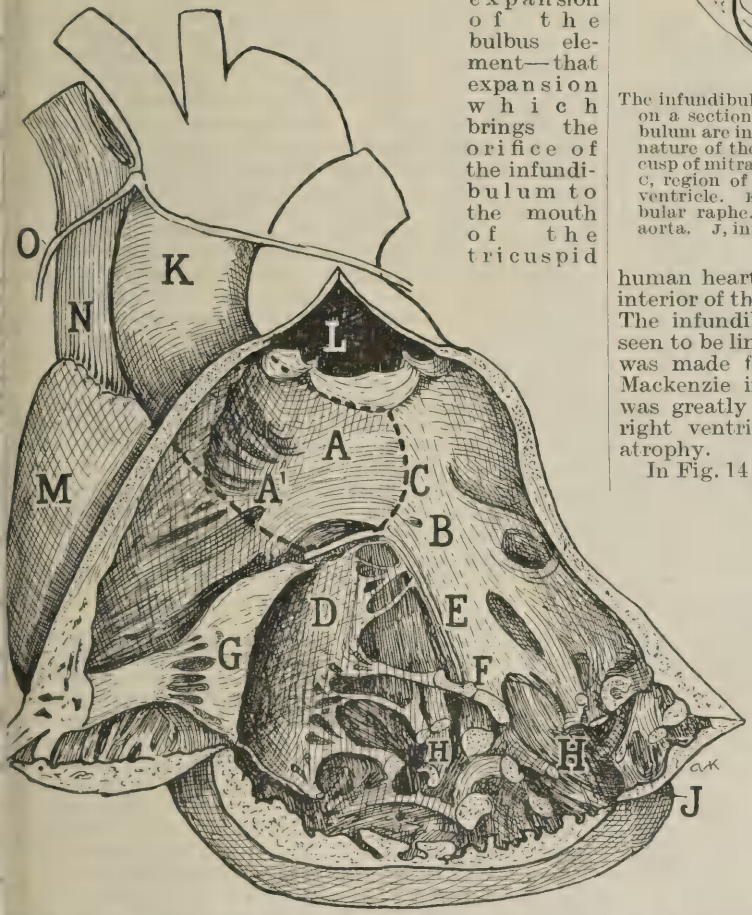
(9) Interior of infundibulum with its lining of longitudinal fibres exposed. (10) Commencement of pulmonary aorta.

separate morphological but also as a distinct physiological element of the heart, we must note its appearance as seen in a basal view, such as is represented in Fig. 12. The orifice of the aorta, with its semilunar valves, which mark the termination of the original cardiac tube, is seen to emerge from the centre of the base, in the angle between the left and right auriculo-ventricular orifices. The lesser curvature of the embryonic heart has disappeared and brought the aortic orifice in juxtaposition with the auricular canal. Both mitral and aortic orifices lie in the embrace of the circular base of the left ventricle. Then in front of the aorta is the pulmonary orifice with, attached to it and forming a very distinct part of the base of the heart, the infundibulum or bulbus element of the right ventricle (Fig. 12, E). The horseshoe fibres of the infundibulum extend towards the right *a.-v.* orifice, becoming continuous with the basal fibres of the right ventricle. Behind the infundibulum and occupying the angle between the aorta and the right *a.-v.* orifice is a peculiar triangular muscular area (Fig. 12, G) which, so far as I know, has hitherto passed unnoticed. I would name it the triangular basal area. Of its nature, I think, there can be no doubt. It is the only part of the anterior base of the right ventricle which has escaped the eruptive expansion of the bulbus element—that expansion which brings the orifice of the infundibulum to the mouth of the tricuspid orifice. A view of the base of the heart confirms the impression that the infundibulum represents a separate functional element of the heart.

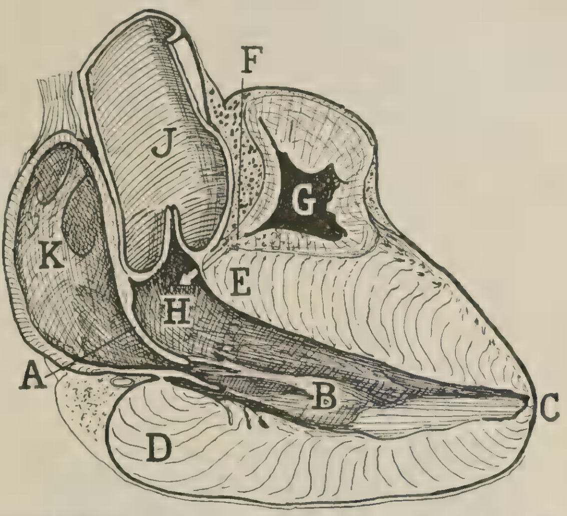
FIG. 15.



he right ventricle of a normal human heart thrown open to show the septal bands of the infundibulum or bulbus element. The ventricle is in a state of relaxation or diastole. A, right septal band, its terminal fasciculi (A^1) ending in the infundibular recesses seen at (C) in Fig. 11. B, left septal band. C, septal raphe corresponding to the origin of the aorta and marking the site at which the bulbus cushions meet and fuse, thus separating the infundibulum from the aortic vestibule D, on the septal cusp of the tricuspid orifice; just above D is indicated the position of the main trunk of the *a.-v.* bundle. E, the right branch of the *a.-v.* bundle descending to the moderator band (F). G, anterior flap of tricuspid valve with musculus papillaris. H H, trabecular parts of the right ventricle formed by delamination. J, apex of left ventricle. K, ascending aorta; the part which lies behind the infundibulum is indicated by stippled lines. L, the commencement of the pulmonary aorta opened up to expose the semilunar valves. M, right auricle. N, superior vena cava. O, pericardium.

Another view of the infundibulum of the right ventricle is given in Fig. 13. The right wall of a human heart has been separated, so as to expose the interior of the lateral wall of both auricle and ventricle. The infundibular cavity is sharply demarcated and seen to be lined with longitudinal fibres. This drawing was made from a heart sent to me by Sir James Mackenzie in 1906—one in which the right auricle was greatly dilated, while the apical region of the right ventricle had undergone a marked degree of atrophy.

FIG. 14.

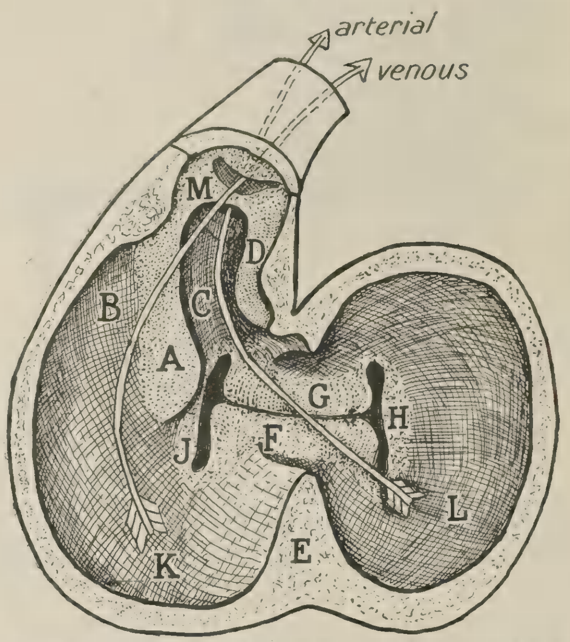


The infundibulum, left ventricle, left auricle, and aorta exposed on a section. The walls of the ventricle and of the infundibulum are in a state of almost complete systole. The separate nature of the infundibulum may be recognised. A, anterior cusp of mitral in section. B, musculi papillares of left ventricle. C, region of apical vortex. D, free or auricular base of left ventricle. E, fixed or aortic base of left ventricle. F, infundibular raphe. G, interior of infundibulum. H, vestibule of aorta. J, interior of aorta. K, interior of left auricle.

In Fig. 14 a view of the infundibular chamber is given in section. The section has been made in such a way as to detach the right side of the heart, including the septal wall of the left ventricle, thus exposing the interior of this chamber. The left ventricle was in a state of almost complete systole. Such a section again emphasises the separate nature of the infundibulum; it can be seen to be superimposed upon and independent of the ventricular system. In such a section as is shown in Fig. 14, an angle or recess is seen to pass towards the base of the adjacent semilunar cusp of the aorta. Along this recess lies the infundibular raphe (see Fig. 15). If this raphe were again opened up as indicated by the arrow on Fig. 14, a developmental stage being thus reproduced, the infundibulum would again communicate with the vestibule of the aorta. As already mentioned, a remnant of the bulbus may persist under the aorta, but usually the subaortic part of the bulb disappears completely and the left ventricle comes by a direct attachment to the aorta. In Fig. 14 the anterior cusp of the mitral is shown in section. The tissue in the base of this cusp represents all that is left of the lesser curvature of the bulbo-ventricular tube of the primitive heart.

In Fig. 15 the dissection of the infundibular or bulbus cavity is carried a stage farther. The right ventricle of a normal human heart has been thrown open; the ventricular musculature is relaxed—in the condition of diastole. On the septal wall of the infundibulum is to be seen the great right septal band (A); it sweeps to the right, over the nearest part of the tricuspid orifice, branching into numerous muscular fasciculi terminating in recesses which were produced as the developing bulbus cavity expanded towards the right auricle. On the left side of the infundibulum is to be seen the left septal band made up of two parts, an upper in which loop-shaped fibres of the infundibulum commence, and a stout raised band which descends on the septal wall of the right ventricle to end in the trabecular musculature of the apical region. On the septal wall of the infundibulum, between the origins of bands A and B, is to be seen an irregular line or raphe (Fig. 15, C) which marks the junction or union of what are now known as the right and left bulbus cushions (Fig. 16). By the union of these cushions the infundibular and progressive part of the *bulbus cordis* is cut off from the retrograde part which becomes included in the vestibule of the aorta. The musculature of the right septal band invades and occupies the right bulbus cushion (Fig. 16, A). In this manner the right septal band comes to have its origin from the root of the aorta. The left septal band invades the left bulbus cushion (Fig. 16 D,) and thus comes into union with the right band and with the commencement of the aorta.

Fig. 16.



From a model made by Prof. J. E. S. Frazer to show a stage in the transformation of the *bulbus cordis* of the human heart towards the end of the sixth week of development. The anterior wall of the ventricle and bulbus have been removed to expose the interior of the heart. A, right bulbus cushion dividing the infundibular or right part of the bulb (B) from the aortic or left part of the bulb (C). D, left bulbus cushion into which grows the musculature of the left septal band. E, interventricular septum; its musculature is entering the posterior endocardial cushion of the auricular canal (F). G, anterior endocardial cushion of auricular canal. H, left or mitral orifice. J, right or tricuspid orifice. K, right ventricle. L, left ventricle. M, the inter-aortic septum with the cushions of the semilunar valves. The arrows indicate the course of blood from the ventricles to the pulmonary and systemic divisions of the primitive aorta. At this stage the left bulbus connects the aorta to the left ventricle. Later, it will become obliterated, bringing the aorta to the level of the endocardial cushions.

In Fig. 15 I have indicated the position of the *a.-v.* bundle, and a glance at its disposition shows us that these septal bands of the infundibulum lie outside the musculature immediately concerned in the ejection of blood from the right ventricle. The main bundle (immediately above D in Fig. 15) marks the upper margin of the true interventricular septum. On reaching the left septal band (B) the bundle at once divides into its right and left branches. The right branch descends on or near the margin of the right septal band to reach the moderator band. All of the right ventricle which lies above the main bundle and in front of its right branch is bulbar or infundibular in origin. The left septal band is developed in all reptilian hearts and has been erroneously identified as the interventricular septum. It is bulbar in its origin, and represents the oldest element now included in the interventricular septum. The right septal band is a later structure, one which appeared during the early evolution of the mammalian heart. Thus, from a structural and historical point of view we have every reason to suspect that the infundibulum of the right ventricle must play a particular and distinctive rôle in the physiology of the pulmonary circulation.

Still more light is thrown on the origin and nature of the *bulbus cordis* if we examine the human heart towards the end of the sixth week of development—a stage shown in Fig. 16. In this diagram—taken from a model prepared by Prof. Frazer, it has been necessary to cut away the anterior wall of the ventricles and of the bulbus to expose the interior of the heart. The process of subdivision of the bulbus cavity is in active operation. On the right side of the bulbus cavity a ridge of endocardial tissue is being formed—the right bulbus ridge (Fig. 16, A). As the musculature of the ventricle spreads upwards to overwhelm the bulbus cavity, part of it invades this cushion and forms the right septal band represented in Fig. 15, A. On the opposite or left-hand side of the bulbus another and older endocardial ridge (Fig. 15, D) is growing towards the right ridge. This ridge, too, becomes invaded by musculature which grows into it from the bulbo-ventricular junction, and in this way the left septal band (Fig. 15, B) comes into existence. At this stage the left or aortic part of the bulbus (Fig. 16, C) forms a long passage leading from the left side of the common ventricle to the aortic valves. As already mentioned, this part of the bulbus becomes obliterated in the course of development, the aortic semilunar valves being thus brought down to lie in front of the auriculo-ventricular canal. The main or right part of the bulbus—the part which forms the infundibulum—has been removed in Fig. 16 to expose the ridges on the interior of the chamber. It is the anterior part of the bulbus—the part which is cut away—which undergoes the greatest degree of expansion.

SUMMARY.

Thus I have laid before you evidence which seems to me to demonstrate that the infundibulum of the right ventricle must be regarded as a distinct constituent of the heart. The evidence supplied by comparative anatomy and by embryology should leave us in no doubt concerning this conclusion. A survey of the anatomy of the infundibulum shows us that, although its cavity is now merged into that of the right ventricle, yet its limits can still be identified. The evidence which is still lacking relates to the exact function of this part of the heart. The evidence of comparative anatomy leads one to regard it as serving as a safety mechanism for the pulmonary circulation. In the hearts of Dipnoi, Amphibia, and Reptilia, the blood which leaves the common ventricle at the beginning of systole passes through the bulbus and is allowed to enter the pulmonary circulation. As the systolic pressure rises the valvular mechanism of the bulbus shuts off the pulmonary circulation, thus safeguarding the vascular network of the lungs. As the systolic pressure rises the bulbus shunts the blood into the systemic aortæ. Certain it is that in the mammalian heart the musculature of the infundibulum passes into action later than that of the body of the right ventricle. Further, I believe that future investigation will show that the infundibular chamber and its musculature only come into effective action during periods of great exertion and stress. At rest the right ventricle of a man pumps about three litres of blood into the lungs per minute, but in periods of stress, as Prof. A. V. Hill has demonstrated, the output may rise to 30 litres per minute. In such conditions of cardiac stress the cavity of the infundibulum intervenes between the driving power of the right ventricle and the pulmonary circulation, and must, I think, exercise a moderating influence.

ENGLISH PSYCHIATRY: NEW LAMPS FOR OLD.

BY EDWIN GOODALL, C.B.E., M.D., B.S. LOND., F.R.C.P. LOND.,

MEDICAL SUPERINTENDENT, CARDIFF CITY MENTAL HOSPITAL; LECTURER ON MENTAL DISORDERS, WELSH NATIONAL SCHOOL OF MEDICINE; PHYSICIAN IN CHARGE OF OUT-PATIENT DEPARTMENT IN PSYCHIATRY, CARDIFF ROYAL INFIRMARY.

THE second instruction to the recently appointed Royal Commission on Lunacy Law and Administration and Mental Disorder is in the following terms:—

> "To consider, as regards England and Wales, the extent to which provision is or should be made for the treatment without certification of persons suffering from mental disorder; and to make recommendations."

To ascertain the extent to which provision is made constitutes an easy task. Always excluding that bright particular star in the psychiatric firmament, the Maudsley Hospital, provision is as good as non-existent, judged by the criterion of what is done in other countries. Neither should the Commission find any difficulty in making up their minds, and quickly, as to the provision which should be made. It so happens that the first report of the Maudsley Hospital for the treatment without certification of persons suffering from mental disorder, upon which THE LANCET published a leading article, has lately been issued.

Allowance must be made for a first report of an undertaking without precedent in this country; nevertheless, in my judgment it furnishes a complete answer to the inquiry as to future practice which is embodied in the above reference. It is much to be desired that the Commission should pay a visit to the hospital.

To appoint a Commission, in this year of grace, to consider whether provision for the above purpose should be made, is in itself a humiliating reflection upon the status of our country in matters psychiatrical. What must they think of us at Utrecht, at Munich, at Boston, at all the numerous centres of medical education on the Continent of Europe and America, at which treatment without certification in psychiatric clinics has for long years been practised?

The first report of the Maudsley Hospital, the material for which, I trust, may be suitably elaborated for publication, is the most refreshing thing in my long experience of British psychiatry, "amidst the encircling gloom" of which it constitutes the "kindly light."

An Out-Patient Department in Psychiatry.

An out-patient department in psychiatry has been functioning, amongst other out-patient departments, at the Cardiff Royal Infirmary once weekly for four and a half years. This was established to pave the way for an indoor clinic which, it was hoped, the passage of an early Mental Treatment Bill might render feasible. In recommending this step to the Committee of Visitors of the Cardiff Mental Hospital and the authorities of the infirmary I realised that the out-patient clinic could never be a complete success without the corresponding in-patient one, the latter to receive not merely borderland but certifiable cases, which, however, need not be certified. It was further recognised that the indoor clinic could not be created merely by the conversion of ordinary hospital wards, or of a taken-over building, but must be erected for the purpose.

In the Maudsley report Dr. E. Mapother states that the out-patient department forms the main channel of admission; 334 out of the total 452 admitted to the wards attended there in the first instance. Most cases go to the out-patient department "with a view to admission to the hospital." "Continued treatment in the out-patient department has been undertaken in relatively few cases so far, for various reasons. Treatment of cases likely to benefit by this is generally more efficacious in the wards." This is entirely in accordance with my experience; I should say that seven-tenths of the cases which I have seen required to be taken in. The lack of wards cripples our efforts in Cardiff. The experience of sending psychopathic cases into the ordinary medical wards of the infirmary, obtained by the kind collaboration of the physicians upon the staff, has shown the unsuitability of this procedure. One has, therefore, only been able, under this grave disability, to do a limited amount of good to applicants for relief. These have been found, for the most part, to be only too ready to go into a suitable hospital, but not willing to go out to the "asylum."

The physician in charge of the clinic also serves a useful function by seeing cases transferred to him from the other out-patient clinics, and cases in the wards upon which his advice is sought. A further useful purpose is served by this clinic in dealing with the patients of the local mental hospital who are out on probation. These cases are finally "signed off" at the clinic.

To those who, proposing to set up a similar out-patient clinic, have consulted me, my recommendation has been to abstain from this course until an indoor clinic in conjunction therewith can be arranged.

The Case for Direct Admission.

I would borrow another peg or two from Dr. Mapother's report upon which to festoon personal experiences. Thus, it is recorded that out of 894 out-patients only 46 were sent from Poor-law hospitals and observation wards. This number is considered disappointing, in view of the very large number of entirely suitable patients suffering from various psychoses who are annually certified in the above institutions and sent to the mental hospitals of the county, and it is suggested that the relative simplicity of procedure favours the continuance of certification of cases which could be sent to the Maudsley Hospital. It would, indeed, appear to be "tawdry easy" to deposit cases at the mental hospital through the medium of the Poor-law. At the annual visit of the Commissioners of the Board of Control to the Cardiff Mental Hospital in December, 1921, the following criticism was made:—

> "On inquiring into the mode of admission here, I regret to learn how few cases are received direct from their homes, no less than 158 out of 169 having been compelled—most of them, I suppose, by a relieving officer's three-day order under Section 20 of the 1890 Lunacy Act—to pass through the Poor-law institution on their way here. In many cases this must be an unnecessarily disturbing proceeding. Cases needing mental hospital treatment should be got there as quickly as possible, and the use of Section 20, framed to meet emergencies, should be restricted to urgent cases."

Looking into this point for the past two years, I find that, in 1922, 95·9 per cent. of males and 91·5 per cent. of females admitted came from the City Lodge, (Union Institution). Like figures for 1923 were 98·9 per cent. and 93·9 per cent., respectively.

Under the scheme for dealing with mental disorders in areas controlled by local authorities which I outline hereunder, cases of insanity would be withdrawn from the administration of the Poor-law, with the exception of senile cases, harmless end-products of the disease, and suitable cases of congenital mental defect. Large numbers of cases are annually received into the Cardiff City Mental Hospital which are obviously cases for a psychiatric clinic in association with a general hospital, unconnected with the lunacy laws, and for which judicial orders and medical certificates—as called for by these laws—and handling by the machinery of the Poor-law are wholly unnecessary and undesirable. Under present conditions there is no alternative.

In 1922, out of an average of direct admissions of 140, I find that 22 left recovered and relieved within three months, 19 within the next three months—or 41 (29 per cent.) within six months. Like figures for 1923, based on direct admissions numbering 192, were, respectively, 53, 25, and 78 (40 per cent.). If two pre-War Office occupation years be taken (1912 and 1913), for 1912, out of 170 direct admissions, 51 left recovered and relieved within three months, 26 within the next three months—or 77 (45 per cent.) within six months; like figures for 1913, based upon 170 direct admissions, were, respectively, 28, 23, and 51 (30 per cent.). In addition to the above, between the opening of the hospital in June, 1908, and 1914 (both dates inclusive), and from January, 1921, to the present time—intervening years being excluded as the hospital was in War Office occupation—35 patients were found "not insane" within a brief period of observation after admission. In my opinion, the great majority of the above cases could have been dealt with at a psychiatric clinic associated with the Cardiff Royal Infirmary, with great advantage to themselves and to students of medicine.

To dwell upon the manifold merits of this system in a medical journal at the present date is wholly superfluous. Something has been done since the Mental Hospitals Association (representing the managing committees of these institutions) was founded in 1919 to enlighten the members upon this subject, and to force to the front the medical aspect of the work which they control. But probably the majority of them are still far from appreciating that the gravest disability from which their recent and acute cases of mental disorder suffer lies in their segregation from the main current of disease, their remoteness from the centres of medical activity, and in the denial to them of the resources of medical science, combined, and applied regularly and systematically.

Briefly, the difference, to my mind, between the medical and non-medical points of view in regard to the matters before the Royal Commission is that the former would put Instruction No. 2 to the Commission first, whereas the latter would consider the order in which the instructions are stated as the natural and correct one, No. 1 reading as follows:—

> "To inquire, as regards England and Wales, into the existing law and administrative machinery in connexion with the certification, detention, and care of persons who are or are alleged to be of unsound mind."

In an article contributed to THE LANCET of Sept. 11th, 1920, entitled "Hospital Treatment of the Psychoses and Psychoneuroses," I described how these maladies could be brought into the comprehensive scheme for the hospital treatment of disease in general described in the interim report of the Consultative Council on Medical and Allied Services, which body was under the chairmanship of Lord Dawson. (What was done with this valuable report?) In it mental disease was merely dealt with, and in my opinion quite inadequately, under "Supplementary Services." I set out how full provision could be made for this form of disease under the main scheme. In this way disorders of health manifesting themselves chiefly, or most dramatically, as disorders of conduct (insanity) would be brought into line, in their early phases, with disorders of health in general, and receive all the benefits of the services of general physicians, surgeons, and specialists in all branches of medicine.

With an enlightened organisation of a service for mental disease on lines such as I venture to sketch hereunder, the function of "asylums" would be limited to the purpose mentioned in the scheme set out. These institutions would, in accordance with the inexorable demands of progress, become of secondary importance; enlargements of them and additions to their number would become increasingly rare, and their maintenance less costly.

Scheme for a Mental Hygiene Service.

I would suggest that the entire machinery for dealing with rate-supported insanity (in its widest sense) and mental defect in a given area be controlled by a Mental Hygiene Board composed of members of the local authority, and, if thought desirable, of coöpted members. This would deal with (*a*) prophylaxis and research, (*b*) early treatment, (*c*) care and treatment of the chronic delusional, other chronic and irrecoverable, (*d*) after-care, and (*e*) mental defect.

(*a*) The clinic in psychiatry would be the source of light and instruction as regards prophylaxis, alike for medical men, nurses, inspectors or similar officials of the Board, social service and after-care workers. There would be lectures on eugenics, on training and education of children, on appropriate occupation for persons with tainted inheritance, &c., and also an ambulatory service of lectures and demonstrations for outlying districts.

The principal clinic—that connected with the medical school—would, of course, be the main centre for research; research flowing in broad streams, and not sparsely trickling, as now, from some 12–13 per cent. of the rate-supported mental hospitals (vide annual reports of the Board of Control). At the best it would be idle to pretend that mental hospitals could compare with the main clinics in number or quality of workers, or in facilities for research.

(*b*) This would be conducted at the clinics (in- and out-patients) and their outlying branches in accordance with the scheme described in the interim report above referred to, with provision for mental maladies. Cases so treated, although mainly, would not only be borderland or early cases (with volition), but also persons definitely insane (without volition), as was properly allowed for in the Mental Treatment Bill, 1923, under adequate safeguards. For none of these would there be any question of judicial orders and certificates. The present asylums (mental hospitals) would only deal with early cases of insanity in so far as such exceeded the capacity of the clinics to deal with. These institutions would deal with cases under (*c*). As the entire financial arrangements under this scheme would be controlled by the local authority, the account for maintenance at mental hospitals would be met by the county or county borough treasurer, and not by the guardians, as now.

I think people should be allowed to enter public asylums as voluntary boarders if they wish to, although I cannot believe anyone would choose this course if provision were made for the treatment of mental disorders in connexion with general hospitals.

(*d*) After-care work would be dealt with by a committee responsible to the Mental Hygiene Board. Our experience in Cardiff will probably be useful in this matter. We have had an after-care system in operation about 18 months. The committee is composed of members of the Cardiff Mental Hospital Committee, of the guardians, and of the Cardiff League of Social Service. Its functions may be set out as follows:—

> To visit homes of patients about to be discharged on trial from the mental hospital with a view to ascertaining social and economical status of household, and to report to the visiting committee, with a recommendation whether or not financial help during the period of trial is desirable, for general maintenance, for purchase of clothes, or of tools, &c. To visit periodically during trial period with a view, generally, to support and advise the patient, and to advise his or her responsible relatives or guardians.
>
> To report to medical officer (who conducts an out-patient clinic at the Cardiff Royal Infirmary) anything desirable

to bring to his notice *re* progress of patient, or apparent slackness of latter in carrying out instructions.

To decide if any money grant desirable for purpose of special medicine not supplied by infirmary. To visit periodically, in suitable instances, after final discharge, and to render help and give advice; especially to assist in obtaining employment for females.

To arrange for rest and change for patients, as far as feasible, pending provision of cottage homes. To visit, at the hospital, patients about to be recommended out, prior to discharge, and others who might be discharged if suitable conditions for them could be arranged.

This committee reports regularly to the Mental Hospital Committee. All cases discharged on trial from the mental hospital attend the out-patient clinic, and are finally discharged by the committee upon a certificate of the medical officer. During and after this period they are under the supervision of the after-care committee. The same thing would, of course, be carried out on a much larger scale with patients of a psychiatric clinic.

The need for convalescent homes (cottage homes, or other) is acutely felt by us in this matter of after-care. These cannot be provided under present conditions, but the Mental Treatment Bill, 1923, contained a clause which allowed visiting committees to make provision for after-care. An after-care committee is an essential part of an organisation for dealing with mental disorders.

Social service and after-care work in connexion with the mentally disordered and defective classes is, like early treatment, in a very backward state in this country, compared with what obtains in the United States, and, I believe, also in Canada. This must be largely due to lack of power on the part of local authorities to spend money on the matter. In this connexion it should be noted that the Mental Treatment Bill provided that any expenses incurred by a visiting committee in connexion with the provision of facilities for early mental treatment—which facilities include hospital in- and out-patient treatment—should be defrayed by the local authority by which the committee is appointed.

(*e*) Mental defectives are already dealt with by the local authority, and would naturally fall to be cared for under the scheme above outlined. The work of a Mental Hygiene Board would, no doubt, benefit by being carried on in liaison with the local public health committee (and vice versa), but the sphere of work of the former is vast—too large, and of too special a nature, to permit of its being merely a branch of the present public health administration. My out-patient experience—and, I am sure, the experience of social service workers would bear this out—convinces me that once a mental hygiene service were in full swing an amount of suffering and disability in the domain of the psychoneuroses would be revealed which would astonish those administering the service.

Local Boards and National Council.

Mental hygiene boards could with mutual advantage work in coöperation with the recently created National Council for Mental Hygiene, which has the same objects, delegating the different aspects of the subject to different committees. I believe this organisation is destined to do good work. Its influence for good would be enhanced and its work facilitated by obtaining the experience and help of local boards, which in their turn must benefit by the experience and opportunities of a National Council which is in touch with like bodies in the United States and other countries. The boards should be represented on this Council.

Messrs. William Heinemann announce for publication early in the new year "Acute Infectious Diseases," a handbook for practitioners and students, by Dr. J. D. Rolleston, senior assistant medical officer, Grove Fever Hospital, based on the author's personal experience of the last 25 years and a study of the literature of some of the commoner acute infectious diseases.

AMŒBIC HEPATIC ABSCESS

TREATED WITH EMETINE ONLY.

By V. S. HODSON, M.V.O., M.B., B.Ch. Oxf.,
M.R.C.P. Lond.

Since publishing the record[1] of three cases successfully treated by this method, I have, myself, only had two cases which could be diagnosed as suffering from liver abscess. Before giving a short account of these I should like to refer to some of the literature.

What is a Liver Abscess?

In the first place, what is a liver abscess? Is it an abscess at all? In the strict sense of the word the answer must be in the negative, as it is no more an abscess than is a gumma, to which it is strictly analogous. The contents of the so-called hepatic abscess are dead and sterile, in contra-distinction to those of an ordinary pyogenic abscess. Abscesses as soon as found require to be opened. This has always been a sound surgical maxim, and as Ciotola[2] has urged, the condition being called an abscess it automatically calls for surgical intervention, whereas there being no abscess in the normal sense of the word, surgical intervention is usually neither necessary nor desirable.

The amœbic hepatic abscess can, for purposes of description, be regarded as consisting of four layers: (1) The contents, which consist of necrosed liver cells, amœbæ—but not invariably—red blood corpuscles, leucocytes, fat droplets, &c. (2) The lining of the cavity. This is very irregular and variable, and dependent on the depth of the destruction of the liver cells. (3) The zone of the amœbæ which are living in the liver tissue, which is undergoing the process of cytolysis. The not unusual failure to find amœbæ in the aspirated material is thus accounted for. (4) The zone of hyperæmia which, as I see it, is defensive, in the sense of actively fighting against the invading organisms, and protective in its endeavour to localise and imprison the enemy and its results.

In the course of his third Lettsomian lecture, delivered in 1922, Sir Leonard Rogers states that he has long thought and has proof that already formed single or multiple abscesses can be cured by emetine, and he mentions that cases have been recorded where patients with obvious abscesses have recovered under emetine without operation, but he adds that it is clearly advisable to hasten recovery by removing the sterile pus. This only serves to show how strong is surgical tradition. Dr. G. C. Low[4] has also written that "in borderland cases between hepatitis and hepatic abscess emetine should be pressed. It is often remarkable how symptoms which almost certainly denoted an abscess may all clear up and disappear under its influence."

Recorded Cases of Cure by Emetine Alone.

The literature is now quite rich in cases in which the diagnosis has been undoubted, and in which the results of medical treatment alone have been even more remarkable for their rapidity and completeness than in those treated with aspiration and emetine. One of the most remarkable is that recorded by Dr. T. R. M. Leonard.[5]

This patient was admitted to hospital on Sept. 18th, 1922 His general condition was serious. Temperature 102·4° F. pulse 102, respirations 36. He was emaciated and very weak and had been ill for three weeks. Scleræ jaundiced, tongue thickly coated. There was decided bulging of the liver below the costal margin for about four inches, and palpation gave the impression of a bag of fluid. Liver dullness extended to the nipple. The right lobe of the liver was also enlarged and palpable. Spleen appeared normal. Lungs and heart normal. Blood examination: malarial parasites present. A decided leucocytosis present. Stools: Ova of ascaris and amœbic cysts. There was a history of previously treated dysentery. Operative measures were refused by the patient, although exploratory puncture showed hepatic pus. Emetine was given gr. 1 mane et nocte. The temperature gradually came down, night-sweats and pain diminished, and the liver enlargement decreased very rapidly, and on the 26th—that is in one week—was normal, pains had gone, and the patient looked and felt considerably better. On the 30th patient was on full diet, and on the following day is noted to have made a complete recovery. He was discharged on Oct. 22nd, 1922.

A very similar case in a European has been recorded by Dr. Ingram Johnson.[6] This case also refused operation. G. L. Hartmann-Keppel[7] has recorded a number of successes for the treatment by medicine alone. He makes it clear that he is recording cases, not of simple or diffuse hepatitis, but definite abscesses of the liver and, on occasions, of respectable size. In Hartmann-Keppel's paper attention is drawn to the fact that in roughly 25 per cent. of cases there are multiple abscesses. As it is more than likely that the second or other abscesses will escape the aspirating needle, it seems fair to presume that, when recovery occurs in such cases, the favourable result is due to the emetine. If one abscess recovers in consequence of emetine it is reasonable to argue that the others would also.

Fatzi[8] concludes his account of a case of hepatic abscess cured with emetine by saying that, in all cases of amœbic hepatic abscess, wherever situated, one ought to give a full course of emetine before thinking of operation. Ciotola,[9] to whom reference has already been made, also reports a successful case, and emphasises the point that no one would think of operating on a gumma.

There are still upholders of active surgical interference, but the general tendency is to substitute aspiration for the larger operation. Bressot[10] sticks to surgery, but he admits the value of emetine. His figures, compared with those of cases treated by the milder method of aspiration and emetine, and with those treated by the mildest method of emetine alone, suggest that he might reconsider the matter with advantage. Ludlow,[11] whose experience is very great, has given up operation for aspiration and emetine, but has not yet taken the next step to emetine alone.

Manson-Bahr, Low, Pratt, and Gregg[12] published a series of 15 cases in which emphasis appeared to be laid on aspiration as having some special intrinsic merit. Its true value is shown in the early part of the article by the description of a case treated by the late Sir Patrick Manson before the days of emetine.

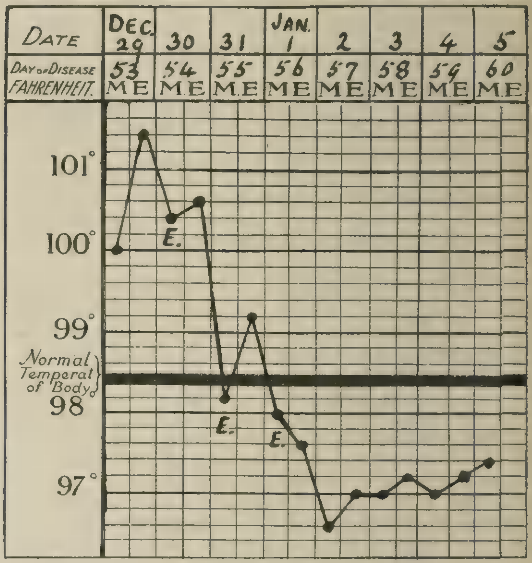
Case 8 seems to me to point the moral of giving emetine a fair trial before resorting to surgery, as in this case a young man had a rib resected to establish free drainage because the pus was too thick to be aspirated. Case 9 is quoted as a case in which a second abscess occurred after a prolonged interval. This is only what one ought to expect to meet with occasionally, and its comparative rarity speaks volumes for the efficacy of emetine in the treatment of amœbic infections. Case 13 is quoted as a recovery as remarkable as it was rapid. Dr. Leonard's case, recorded above, treated with emetine only compares very favourably with this patient. Case 14 is referred to specially for its short stay in hospital. Comparison should be made with my second case recorded below. Case 15 has a special interest for me. The patient was explored under a general anæsthetic and 3 oz. of very thick pus were aspirated. Symptoms partially relieved but gradually returned in spite of intramuscular emetine injections. The case is stated to be of interest as showing that emetine alone will not necessarily effect a cure without aspiration. This is, of course, not the only possible finding on the evidence. The effect of emetine is to kill off the amœbæ in the liver tissue so that, there being no longer an enemy to fight and contain, the circumferential hyperæmia automatically disappears and the direction of the flow, which for reasons of defence and protection had been centripetal, becomes centrifugal. The removal, therefore, of the abscess contents does no good but, owing to alterations of tension and of the natural direction of flow, is an interference which I regard as more likely to impede than assist the process of recovery.

Case Records.

My two cases are as follows:—

CASE 1.—This patient had already suffered and recovered from an amœbic hepatic abscess before I saw him on this occasion. He was one of my previous cases, when his abscess was in the lower part of the right lobe. His health had been completely satisfactory and he had been at work for the greater part of the time that had elapsed between the two attacks. I therefore regard it as justifiable to presume that the first abscess was cured and that the second arose de novo. On the occasion of his second illness the patient had been ill for some time before I saw him, and by the time he came to me the diagnosis was easy and the abscess quite impossible to miss. He was given emetine gr. 1 without delay, and the accuracy of the diagnosis was confirmed by the bursting of the abscess through the lung about two hours later. Recovery in this case was complete and uneventful on adequate doses of emetine, and when last seen he was in excellent health.

CASE 2.—This patient had rather a long history before I saw him. On admission to hospital he had enlargement of the liver in an upward and downward direction, with definite and localised bulging and tenderness below the costal margin. This man came under my care on Dec. 29th, 1923, and in addition to the local disease he was very anæmic and obviously very ill. Emetine in gr. 1 doses was given on the 30th and 31st, and on Jan. 1st, 6th, 7th, 13th, 14th, and 20th, 1924. When last seen on the 20th he was entirely restored to health. I attach his temperature chart while he was in hospital.



Temperature chart. E. = Emetine gr. i.

Conclusions.

As it has now been conclusively proved that even a large amœbic hepatic abscess can be entirely absorbed after and in consequence of the administration of emetine alone, I urge that surgical measures of all sorts should no longer be regarded as necessary until emetine has been given a fair chance. In the recorded cases improvement is very rapid, so that there is no long delay in decision as to success and failure, and no harm is done to the patient who, in a very high percentage of cases, is spared the trouble and anxiety which attaches to anæsthetics, aspirations, and other surgical interferences. There are two diseases which are analogous in many respects which no one in the one case and few in the other think of dealing with by active surgical interference. The gumma has been referred to, but the modern treatment of bone tuberculosis is the second obvious analogy, and only differs from the gumma and the amœbic hepatic abscess because in these there is the specific remedy to kill off the invading organisms, while in the case of tuberculosis the process of cure depends entirely on the destruction of the tubercle bacilli by the natural defence processes of the individual. In all these diseases once the cause has been removed the absorption of its more or less fluid effects offers no difficulty, and occurs with very great rapidity and completeness.

I should like to acknowledge my indebtedness to the *Tropical Diseases Bulletin*, which has furnished me with all my references.

(*Continued at foot of next page.*)

HYPOGLYCÆMIA.

BY P. J. CAMMIDGE, M.D. LOND.

THE clinical importance of hyperglycæmia has been recognised for a considerable time, but it is only since the introduction of the insulin treatment for diabetes that attention has been generally directed to the converse condition of hypoglycæmia. The discovery by the Toronto workers that the sudden introduction into the body of an excess of the internal secretion of the pancreas is liable to give rise to a series of characteristic symptoms which are associated with a rapid fall in the percentage of sugar in the blood is not the least important of the contributions to our knowledge made by these observers, for, apart from its practical value, it helps to throw light on the mechanism by which the normal sugar content of the blood is maintained.

The investigations I have carried out in conjunction with Mr. H. A. H. Howard and Mr. Cairns Forsyth have shown that (1) the fasting level of the blood-sugar is remarkably constant among mammals and is not related to their habitual diet; (2) the time and space relations of the variations in the sugar content of the blood following the ingestion of food are also strikingly similar in herbivorous, carnivorous, and omnivorous animals; (3) the upper limit attained by the blood-sugar after a meal is practically the same in all mammals, and is not directly dependent upon the amount of food taken or the nature of the diet, provided a certain minimum has been consumed.[1] Our observations have led us to the conclusion that the percentage of sugar in the blood, both in the fasting condition and after a meal, is determined by the interplay of a number of influences, some of which accelerate the production of sugar, while others inhibit the process and promote the formation of glycogen, but that under average conditions the food itself takes no direct part in the process.

Influences Regulating Sugar Content of Blood.

The most important influence regulating the sugar content of the blood is the balance between the activity of the glycogenolytic ferment of the tissues, particularly the liver, and a brake-like action exerted by the internal secretion of the pancreas over glycogenolysis. In the fasting state, this balance being constant in all mammals, the conversion of glycogen into sugar is also constant, and the sugar content of the blood varies therefore within very narrow limits, but when the balance is upset by the formation of the digestive secretions after food has been taken there is a temporary diminution of the control of the pancreas and a relative increase in glycogenolysis, with the result that the sugar content of the blood rises to a similar extent in herbivorous, carnivorous, and omnivorous animals, until the control of the pancreas is once more fully exerted, when it returns to the fasting level. This being the case, it is obvious that if the pancreatic brake is loaded, as it were, by introducing into the circulation an abnormal supply of the internal secretion of the pancreas from an extraneous source the sugar content of the blood will sink below the fasting level when no food has been taken, and the usual increase after a meal will be prevented, if the injection is given at an appropriate time before; effects which it is now well known insulin induces.

Hypoglycæmia may be produced in other ways than by artificially overloading the pancreatic brake, however. There is no evidence that an excess of the internal secretion of the pancreas is ever formed naturally, but there is both experimental and clinical evidence that a sub-normal sugar content in the blood may arise from defective formation of its glycogenolytic ferment by the liver. Our experiments upon animals have shown that when the hepatic functions are interfered with by the administration of a liver poison such as hydrazine phosphate, the percentage of sugar in the fasting blood sinks proportionately to the dose, and that when food is given the resulting blood-sugar curve is abnormally low until the animal has recovered from the effect of the drug; at the same time there is a corresponding fall in the amylolytic ferment of the blood, which as I have shown, is derived mainly from the liver. Other liver poisons, such as phosphorus, have a similar effect and give rise to hypoglycæmia. Mann has proved that the percentage of sugar in the blood diminishes steadily after the removal of the liver in animals, and that when it reaches about 0·05 per cent. characteristic symptoms appear and death soon follows. Life may be prolonged by the intravenous injection of dextrose, but a fatal termination cannot be prevented. More recently, Mann and Magath[2] have found that when the liver and pancreas are removed at the same time, the resulting condition is the same as though only the liver had been removed, and that even when the liver is excised from 24 to 96 hours after pancreatectomy the sugar content of the blood rapidly diminishes, and the same characteristic symptoms develop as after hepatectomy, although at a higher blood-sugar level. Here again glucose injections temporarily restore the animal to a normal state, but the effect is only transitory.

Mild Forms of Hypoglycæmia.

Mild forms of hypoglycæmia, due apparently to defects in the functional activity of the liver, are not at all uncommon. As a rule the patient's chief complaint is that he is lacking in energy and is easily tired, consecutive thought is difficult, and work requiring concentration is only carried out with effort. The symptoms are most pronounced in the morning and diminish as the day passes, especially if small frequent meals are taken. In the severer forms attacks of giddiness and even incoördination of movement are experienced.

In April, 1923, I was asked to advise a man, aged 46, who gave a history of the above symptoms dating back for about two years. Up to the age of 30 he had been a keen athlete, but subsequently became immersed in a sedentary occupation and took little exercise. As a consequence he suffered from constipation, and was troubled with heartburn and flatulency. He gradually lost his appetite, slept badly, and was frequently disturbed by nightmare. He had been subject to hay fever since a child, and latterly had had several attacks of urticaria, but otherwise had suffered from no definite illness. In the early part of 1918 he became very despondent and found his work a trouble. Subsequently he noticed he was easily tired, especially in the morning, but that he was better after a meal, and consequently formed the habit of eating food between his regular meals. Later in the year he began to suffer from attacks of "giddiness." At first these were slight and transitory, only occurring after unusual exertion, but ultimately he had several severe attacks while walking, and of such a type that his friends came to the conclusion he was intoxicated. As he was a total abstainer, he was greatly annoyed, and determined to have his condition thoroughly investigated. Examination of a 24-hours' collection of his urine showed no albumin, no sugar, and no acetone, but there was a marked excess of indican and a very pronounced reaction for urobilin. Quantitative analysis revealed an excess of amino-acid nitrogen (0·6 g.), but no other striking abnormality. A specimen of blood withdrawn from a vein, fasting, gave normal values for all the inorganic elements, but showed an excess of uric acid (10 mg. per cent.), amino-acid nitrogen (10 mg. per cent.), and phenol (14 mg. per cent.), with a low blood-sugar (45 mg. per cent.). These results pointed to there being abnormal decomposition in the

contents of the intestine, with hepatic insufficiency and consequent toxæmia and hypoglycæmia. Examination of the fæces tended to confirm the diagnosis of abnormal decomposition in the contents of the intestine, and showed there was excessive peristalsis in the upper part of the bowel, but there was no evidence of any deficiency of pancreatic digestion. A serial examination of the patient's blood after a test breakfast containing protein 15 g., fat 40 g., and carbohydrate in the form of starch 40 g., but with no actual sugar, worked out as shown in Table I.

TABLE I.

Time taken.	Sugar per cent.	Difference value per cent.	Erythrocytes per c.mm.
Fasting	0·045	0·005	5,000,000
Breakfast :	+	+	+
½ hour after	0·069	0·004	4,960,000
1 ,, ,,	0·085	0·005	4,960,000
2 hours ,,	0·078	0·015	4,940,000
3 ,, ,,	0·045	0·035	4,900,000
4 ,, ,,	0·040	0·055	5,000,000

From Table I. it will be seen that, starting from a fasting value of 0·045 per cent., the maximum point attained by the blood-sugar was 0·085 per cent. one hour after the meal. The normal difference value before the meal and for an hour after was against there being any deficiency of the internal secretion of the pancreas, but the rapid rise in the third and fourth hours tended to confirm the diagnosis of hepatic insufficiency. No evidence of any serious disturbance of the functions of the other ductless glands was discovered. Next day the patient was given glucose 50 g., fasting, with the results shown in Table II., A.

TABLE II.

Time taken.	A. Dextrose 50 g. sugar per cent.	B. Lævulose 50 g. sugar per cent.
Fasting	0·045	0·050
¼ hour after S.	0·080	0·090
½ ,, ,,	0·090	0·124
1 ,, ,,	0·100	0·160
1½ hours ,,	0·088	0·122
2 ,, ,,	0·050	0·060

The character of the blood-sugar curve obtained tended to exclude any true diabetic tendency, but was consistent with a diagnosis of hepatic insufficiency. No sugar was found in the urine passed during the two hours of this test. It is noteworthy that on this day the patient volunteered the information that he felt better than he had done for some months. When a tolerance test with 50 g. of lævulose was tried the following day the maximum level attained by the blood-sugar was considerably higher than when dextrose had been given (Table II., B.), and examination of the urine passed during the two hours of the test showed that 5 g. of lævulose had been excreted, thus proving that lævulose was not metabolised as completely and efficiently as dextrose. A consideration of all the facts elicited by these examinations suggested that the patient's symptoms were due to hypoglycæmia dependent upon defects in the functional activity of the liver, accentuated by a toxæmia of hepatic and intestinal origin. He was treated accordingly, and has since had no recurrence of the "giddy" attacks, nor has he had any difficulty in carrying out his work, or in taking a reasonable amount of exercise without undue fatigue.

Rate of Conversion of Glycogen in Liver.

The rate at which glycogen is converted into sugar in the liver is largely determined by the control exerted by the internal secretion of the pancreas, but it is also influenced by the internal secretions of the other ductless glands and by the nervous system. The injection of epinephrin or pituitrin is the recognised method of rapidly mobilising sugar from the glycogen stores of the body to counteract the effects of an overdose of insulin, while, on the other hand, it is well known that hypoglycæmia occurs in Addison's disease and certain forms of hypopituitarism. Disturbances of carbohydrate metabolism due to defects in the functions of the ductless glands other than the pancreas are more common than is generally supposed, hyper-functions of the pituitary, thyroid, or suprarenals giving rise to a glycosuria which is eventually converted into a true pancreatic diabetes when secondary exhaustion of the pancreas supervenes, as it invariably does if the hyperglycæmia is not controlled by appropriate treatment, whereas hypo-function of these glands results in a diminished carbohydrate tolerance and a subnormal percentage of sugar in the blood, with consequent symptoms of perverted metabolism in other structures of the body. In the present state of our knowledge it is only possible to diagnose defects in the functions of the suprarenals in their earlier stages by exclusion; disturbances in the functions of the thyroid may be recognised by determinations of the basal metabolism and by Kottmann's test; hyper- or hypo-pituitarism may be inferred from the variations in the volume of the blood which take place after the ingestion of food, the former being associated with a dilution and the latter with a concentration as the percentage of sugar rises following the meal.

Blood-Sugar and Pituitary Function.

The increase in the percentage of sugar found in the blood after a meal in cases of pituitary disease is obviously not a true index of the actual state of carbohydrate metabolism, for in hyper-pituitarism the values obtained are too low, owing to the dilution which occurs, and in hypo-pituitarism they are too high, in consequence of the concentration which takes place as more sugar passes into the circulation. If a correct estimate is to be formed, the dilution in the one and the concentration in the other must be allowed for, otherwise a hyperglycæmia may be masked, or the true extent of a hypoglycæmia may not be recognised. The simplest method of detecting and estimating rapid changes in the volume of the blood such as occur in these cases is by making an erythrocyte count each time a sample of blood is taken for analysis; variations in the number of red cells per c.mm. distinctly in excess of the limit of experimental error will then show whether the blood is being diluted or concentrated and indicate the extent of the change. Normally, and in most cases where there are defects of carbohydrate metabolism, no material alteration takes place in the volume of the blood after a meal, and in my experience the occurrence of such a change is diagnostic of disturbances in the functions of the pituitary.

In March, 1922, I was consulted regarding a gentleman who had suddenly commenced to put on weight, and had at the same time become very lethargic and easily tired, a few months previously. A full chemical analysis of his fasting blood showed that most of the constituents, organic and inorganic, were abnormally low, excepting uric acid, which was absolutely high and relatively present in excess. A serial analysis of his blood before and after a test breakfast worked out as shown in Table III.

TABLE III.

Time taken.	Sugar found per cent.	Diff. val. per cent.	Erythrocytes.	Sugar allowing for vol. changes.
Fasting	0·050	0·004	3,600,000	0·050
½ hour after B.	0·150	0·000	5,600,000	0·096
1 ,, ,,	0·110	0·000	4,700,000	0·084
2 hours ,,	0·060	0·008	3,800,000	0·057
3 ,, ,,	0·050	0·004	3,500,000	0·050
4 ,, ,,	0·050	0·004	3,480,000	0·050

The figures in Table III. showed a low percentage of sugar before a meal, then a sharp rise half an hour after, followed by a rapid fall to slightly below the fasting level at the third hour. Comparison of the erythrocyte counts suggested that the wide sudden alterations found in the percentage of sugar were largely due to variations in the concentration of the blood, and that there was really much less change in the absolute amount of sugar, for if allowance is made for the varying volume indicated by the red cell counts, the figures shown in the last column of Table III. would be obtained. A test-meal of 50 g. of dextrose given the next day was followed by a blood-sugar curve of normal form and time relations, but, although the maximum percentage attained was not so high as is usually the case, an appreciable amount of sugar was excreted in the urine between half an hour and an hour and a half after it was taken. (Table IV.)

The glycosuria was probably due, in part at least, to the fact that the calcium content of the blood was abnormally low, 3 mg. per cent., thus causing unusual permeability of the kidneys for dextrose. The normal difference value of the fasting blood was against there being any deficiency of the external secretion of the pancreas, but the rise after the test-meal at the second hour, and following the glucose at the hour, pointed to there being some disturbance of the functions of the other ductless glands; as there was pronounced concentration of the blood when the percentage of sugar rose after the test-meal, hypo-function of the pituitary seemed the most likely diagnosis, possibly associated with defects in the parathyroids, which would account for there being an absolute as well as a relative deficiency of calcium in the blood. The effects of treatment tended to confirm this conclusion, for the patient quickly dropped to his normal weight and recovered his physical and mental vigour on a preparation containing pituitary and parathyroid. He has since had no recurrence of the symptoms as long as the gland preparation was being taken, but when an attempt was made to discontinue it they rapidly returned, so that the glandular deficiency would seem to be permanent.

TABLE IV.

Subnormal Percentage of Sugar in Fasting Blood.

A subnormal percentage of sugar, under 0·07 per cent., in the fasting blood is apparently always due to defective glycogenolysis arising from faults in the functions of the liver or lack of balance between the ductless glands, and particularly deficiency of the pituitary or thyroid. Sometimes, however, cases are met with where there is no evidence of any deficiency of the thyroid or pituitary, the sugar content of the fasting blood is not strikingly low, and yet glycosuria occurs after each meal with a blood-sugar which fails to reach the normal maximum. These are generally described as examples of "renal glycosuria," but, in many at least, the name is not altogether a happy one, since the primary cause of the condition is not in the kidneys. The whole blood analyses I have been carrying out in all my cases of glycosuria for some years have shown that in such cases there s almost invariably a low percentage of calcium, and I have found that treatment with calcium and parathyroid raises the percentage of sugar and usually prevents the glycosuria. It would therefore seem that the hypoglycæmia and excessive permeability of the kidneys for dextrose are essentially dependent upon defects in the functions of the parathyroids, and that the term "renal glycosuria" gives a misleading mpression of the true pathology of the condition.

As an example of this type of hypoglycæmia I may quote the case of a lady, aged 30, who was sent to me for treatment in March, 1922. Sugar had been discovered in her urine accidentally in 1920, and, although she had undergone several courses of treatment in the interval, the glycosuria had persisted. On making a serial analysis of her blood after a test breakfast, results were obtained as shown in Table V.

TABLE V.

Time taken.	Sugar per cent.	Diff. val. per cent.	Erythrocytes per c.mm.
Fasting	0·080	0·004	4,870,000
½ hour after B. ..	0·060	0·002	4,990,000
¾ ,, ,, ..	0·080	0·000	4,930,000
1 ,, ,, ..	0·090	0·000	4,930,000
2 hours ,, ..	0·100	0·006	4,940,000
3 ,, ,, ..	0·090	0·010	4,920,000
4 ,, ,, ..	0·080	0·020	4,930,000

The sugar content of the fasting blood was normal, and although traces of sugar were found in the urine passed after the meal, there was no hyperglycæmia—in fact, the percentage of sugar in the blood failed to reach the maximum level of about 0·14 per cent. usually attained by a healthy person after such a meal. The next day after 50 g. of dextrose had been taken, fasting, another serial analysis of the patient's blood worked out as shown in Table VI.

TABLE VI.

Time taken.	Sugar per cent.	Diff. val. per cent.	Erythrocytes per c.mm.
Fasting	0·080	0·004	4,870,000
¼ hour after D. ..	0·090	0·002	4,860,000
½ ,, ,, ..	0·104	0·004	4,860,000
1 ,, ,, ..	0·112	0·000	4,870,000
1½ hours ,, ..	0·100	0·004	4,860,000
2 ,, ,, ..	0·084	0·004	4,860,000

These results, like those given by the previous test, showed that there was no serious interference with carbohydrate metabolism, in spite of there being 3·2 g. (1·4 per cent.) of dextrose in the urine passed during the two hours of the test. Examination of the fæces revealed no abnormality, and an analysis of the whole blood gave normal figures excepting for calcium, which stood at 2·0 per cent., compared with the normal of 5·3 to 6·8 per cent. It seemed probable, therefore, that the persistent glycosuria from which the patient suffered was dependent upon excessive permeability of the kidneys for dextrose owing to a low calcium content of the blood serum. She was accordingly given calcium and parathyroid by the mouth, and allowed an ordinary mixed diet. On the first day after the treatment was commenced 10 g. of sugar were excreted in the urine, the next day the output dropped to 4·9 g., and the day after that to 3 g., at which it stood for two days more, after that no trace of sugar could be detected by Benedict's test. The treatment was continued for two months, then, as the urine had remained sugar-free, it was discontinued, and there has since been no recurrence of the glycosuria.

Cases are occasionally met with where parathyroid and calcium therapy has little or no effect on the hypoglycæmia and glycosuria; such are probably examples of essential renal glycosuria due to primary renal permeability, for all the chemical constituents of the blood, and not only the calcium, are present in subnormal percentages, although there is no reduction in the red cell count, and no evidence of defective carbohydrate metabolism.

Other causes of hypoglycæmia may occur theoretically, and probably exist, but those I have described appear to be the most frequently met with in clinical practice. It is interesting to note, however, in view of the statements recently made that substances having a similar effect on the blood-sugar to insulin have been prepared from animal tissues other than the mammalian pancreas and also from yeast and other vegetable sources, that injections of peptone or guanidine give rise to hypoglycæmia. The diagnosis of hypoglycæmia presents no difficulties if serial analyses of the blood are made under controlled conditions, and, as a rule, the probable cause can be determined with the help of the methods to which I have referred. Symptomatic treatment is only of temporary benefit, as is also the case with the converse condition of hyperglycæmia. If permanent improvement is to be effected in either, the ætiology must be worked out as completely as possible, and suitable measures must be taken to deal with the primary factor to which the particular disturbance of carbohydrate metabolism is ultimately due.

A cheque to complete £1000 for the Linen Fund of the Royal Free Hospital, inaugurated by Princess Marie Louise, was presented to her on Dec. 9th at the annual meeting of the Guild of Help.

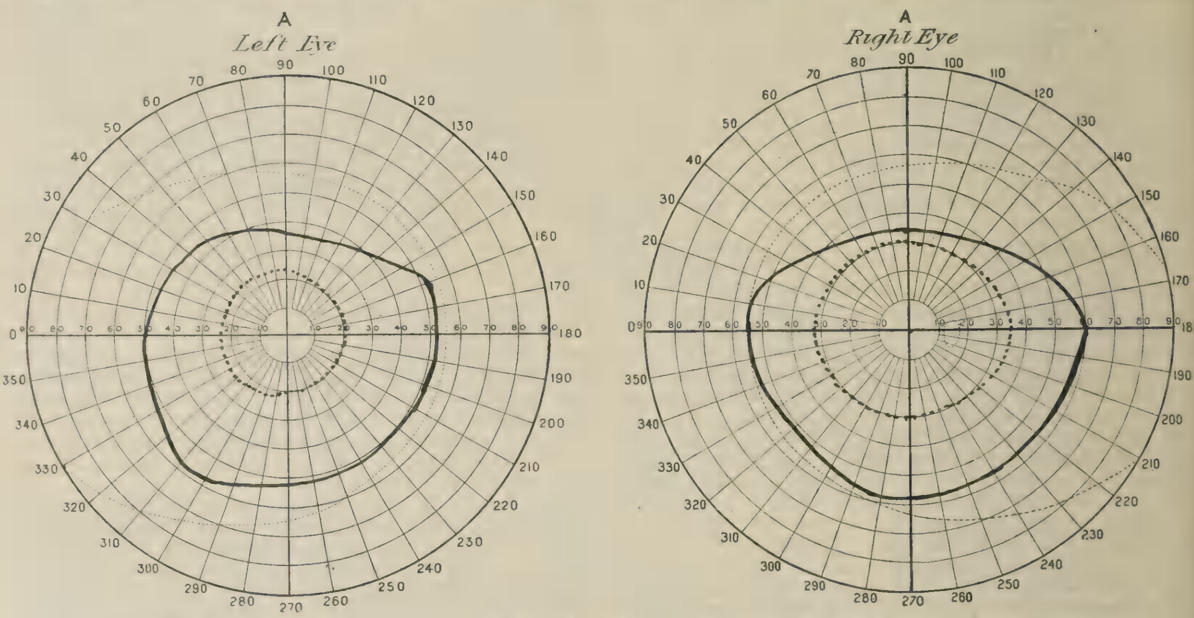
LIVINGSTONE COLLEGE.—The report of Livingstone College for the year 1923–24 states that in the 32 years which have elapsed since the College was founded 810 students have entered for the full course or for part of it, of whom 540 are still at work. The courses of the College are intended to supply missionaries who work in places where qualified medical aid is not immediately or even remotely obtainable with a minimum of medical knowledge. In the years since the war the number of prospective missionaries attending the College has fallen considerably, and financially the College does not receive the support which it deserves. It has a cash deficit of about £380, and there is need for structural repairs which the management cannot afford.

Clinical and Laboratory Notes.

A CASE OF
LATENT NASAL ACCESSORY SINUS DISEASE,
WITH MENTAL AND VISUAL IMPAIRMENT; OPERATION; RECOVERY.

By E. Watson-Williams, *M.C.*, M.B., M.Ch. Camb., F.R.C.S. Edin.

The following case is of unusual interest as illustrating a rapid recovery from very pronounced mental impairment, after treatment of a septic focus.



Visual fields for white. .... on April 12th, 1924. ———— on Sept. 3rd. No scotoma.

X. Y., male, aged 42, came to me early in February, 1924, complaining of running left ear. A radical mastoid operation had been performed in 1917, but the cavity had discharged ever since. There was a history of recurrent "catarrh," but never cacosmia. Nasal sinus disease was suspected, but on several inspections no definite evidence was observed.

At the end of March he complained of feeling very tired and depressed, unable to do his work, and of failing vision. His wife reported that his manner had recently become very "queer," and that his memory was failing. On inspection a definite post-nasal discharge was seen, mucoid in character. The man was at once admitted to hospital.

The report on his vision was as follows. Right eye, 6/12; left eye, 6/24. Visual fields much contracted. No scotoma. (See figure.) Wassermann reaction was negative; no history of syphilis.

Under local anæsthesia I explored the nasal accessory sinuses by the suction syringe method. The washings showed :—

Sinus.	Macroscopic appearance.	Microscopic appearance.	Culture result.
Right antrum.	Thick pus.	Pus.	*Staphylococcus aureus.*
Left ,,	,,	,,	,,
Right sphenoid.	Small flocculus of mucus.	Mucus.	No growth.
Left ,,	Clear return.	Nil.	,,

Colloidal silver was injected into all the cells.

Following this, there was a considerable improvement in the mental condition for a time, although he did not become fit to return to work. The vision remained the same, almost identical fields being found in the middle of May. By this time, however, the mental condition again became dull and clouded; his family doctor particularly noticed this. It was, in fact, our great difficulty, for the man refused operation, and it seemed impossible to get him to realise his danger. At this time, also, left sciatica, formerly not severe, became so bad that injection of the nerve was advised. I wished, however, to see whether an attack on the focus of toxic absorption would not do as much for him.

Eventually persuaded, he was early in June admitted to hospital, and I performed a double per-nasal antrostomy. Convalescence was uneventful, and he was so far recovered that he returned to work at the beginning of August. I saw him again in September, and made the following note: "His mind is clear, his memory good, he says his sight is perfect except for small print, and he feels and looks well." The ear healed, and he was not troubled with any sciatica. Seen again in October, the condition was as good. He has not lost work since he returned to it, and does a full day without difficulty. The figure shows the visual fields on Sept. 3rd. There is still some contraction, but much less than in April. Vision in both eyes 6/5.

The favourable result in this case was probably largely due to the operation not having been unduly postponed. The patient was employed delivering packages on a regular round: so marked was the dulling of intelligence, that he began to bring his employers' property home, unable either to remember where to deliver it or to realise that he should properly dispose of it. At one time, indeed, it seemed that his destination would be an asylum—or perhaps prison.

Clifton, Bristol.

A CASE OF
SYPHILITIC INFECTION IN A PATIENT SUFFERING FROM YAWS.

By Alan McKenzie, M.B., B.S. Lond.

(*From the Medical and Public Health Department, Rarotonga, Cook Islands.*)

The case here recorded is of considerable interest, although, owing to lack of laboratory facilities, a fuller investigation was impossible.

A male Polynesian, aged 20, was admitted to hospital in March, 1922, for a large traumatic ulcer of the leg and foot. Local treatment was applied, but the ulcer was slow in healing. It did not, however, present any abnormal features.

About April 1st I noticed a large number of "pimples" over his face and chest. Each of these was surrounded by a small area of desquamation. Two days later a small yellow spot was visible in the centre of each pustule, and in a few days they had developed into typical yaws. Each pustule was raised and of the size of a sixpence, and the bulk of the tissue was made up of the yellow cheesy matter distinctive of yaws.

He was treated with three injections of N.A.B. at intervals of a week, in all 1·1 g. of N.A.B. being given. I left on tour immediately after the last injection, and did not see him again until Feb. 20th, 1923. On the occasion of the last injection all the yaws had disappeared, and pigmented skin only was left.

He presented himself this year on account of a sore lip and nose. The lip, over an area of half a square inch, was covered with a typical secondary mucous syphilide. The meatus of the right nostril was occupied by a secondary yaw, typical in form. On making a more complete examination I discovered a large yaw between the nates, while on the penis was a hard Hunterian chancre occupying the prepuce. The inguinal glands were enlarged and hard. He also gave me a history of a recent sore throat. The chancre had appeared 10 days to a fortnight after intercourse with a known prostitute, and the other lesions had all appeared very shortly afterwards.

Under N.A.B., in weekly doses of 0·9 g., the symptoms rapidly cleared up and the patient is now quite free from obvious lesions. I made smear preparations from each lesion, and stained them with Giemsa, but saw no spirochætes.

To me this appears undoubtedly a case of syphilis following upon a partially cured attack of yaws. I have no doubt that when I examined the patient in February he was suffering from both yaws and syphilis. As a very tentative suggestion, might not the second attack of yaws be due to some residuum of infection from the previous attack exalted in virulence (or more probably by the using up of antibodies) by the invasion of a very closely allied organism? Still probable, perhaps, is a fresh infection with *S. pertenue* since, in my experience, there is no resistance to reinfection after the disease has apparently been cured. I have seen four cases of reinfection in which I have been certain of the primary sore in the second attack, and am convinced that the question of a relapse need not be entertained.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

COMBINED SECTIONS OF MEDICINE, OTOLOGY, NEUROLOGY, AND LARYNGOLOGY.

NON-TUBERCULOUS MENINGITIS.

A MEETING of these combined sections was held on Dec. 10th, with Dr. ROBERT HUTCHISON, President of the Section of Medicine, in the chair, when a discussion took place on the causes, early recognition, and treatment of non-tuberculous meningitis.

The Point of View of the Physician.

Dr. HUGH THURSFIELD, who opened, said that the practice, during the past 25 years, of puncturing the spinal theca and examining the condition of the cerebro-spinal fluid, rare before that time, had added considerably to knowledge concerning pathological lesions of the meninges, yet many problems still awaited solution. One was the exact position of the condition known as meningismus. Clinically, there were cases presenting all the signs and symptoms characterising meningeal inflammation, yet with an apparently normal cerebro-spinal fluid. This was most frequently associated with the acute infections of children, such as pneumonia; also with marasmus, and in the acidosis and acetonæmia of older children. It was found, by laboratory experiment, that there was a stage in the development of meningitis when the cerebro-spinal fluid appeared to be normal, and he considered that meningismus was the first stage of a true meningitis, a stage in which the defensive mechanism prevented the onset of a further stage. The next degree, that of serous meningitis, came more before aural surgeons than physicians. In this stage there were changes in the protein content of the fluid and in the number of cells present in it, though on culture it was sterile, and the films showed no organisms. His experience of instances which passed to the frankly purulent stage was confined to a few cases of epidemic cerebrospinal fever which he saw in the first two years of the war. But this knowledge did not lessen the difficulty of the problem; it was necessary to learn to distinguish the cases of meningitis which were severe and dangerous from those of meningitis in which recovery was the rule. It was also necessary to recognise cases in which the cerebro-spinal fluid afforded evidence of true inflammation, and those in which, with all the symptoms and signs of meningitis, including profound changes in the fluid, the result was quite favourable.

What symptoms and signs, he asked, justified the diagnosis of meningitis? Mainly, the symptoms were those of any cerebral disturbance—headache, vomiting, delirium, coma, stupor; and among the signs squints, transient paralyses or clonuses, Kernig's sign, or Brudzinski's sign. Alterations in the cerebrospinal fluid placed the diagnostician on a much firmer footing. His view was that the normal cerebrospinal fluid was that which issued from the theca at the rate of about three drops per second, contained 0·025 per cent. or less of albumin, reduced Fehling's solution, had not more than ten cells per c.mm., and was sterile on cultivation. Such a fluid was met with in meningismus, in pneumonia, and other acute fevers. When a focal infection existed in the vicinity of the meninges, as in some mastoid infections, there was some increased albumin in the fluid, or a greater number of cells, but it was still sterile. In association with mumps both albumin and cells might be very greatly increased, such increase lasting only a few days. Sometimes poliomyelitis commenced with all the symptoms of meningitis, and these cases it was often difficult to differentiate from those of tuberculous meningitis (the consideration of which was outside the present discussion, as also was meningococcal meningitis). A very large number of organisms had been charged with causing meningitis; and in the great majority of all forms of meningeal infection there was a septic focus, in ear, or bones, or viscera, or in one of the great serous cavities of the body, possibly in the sphenoidal or ethmoidal sinuses, where an unsuspected focus could lurk. The pneumococcus and the influenza bacillus on occasion invaded the meninges without preliminary warning, and it was particularly true of the second-named. He had his doubts as to it being identical with the organism described by Pfeiffer. Without lumbar puncture it was impossible to diagnose primary pneumococcus and primary influenza cases from those due to the meningococcus.

Generally, the march of the case was so rapid that little was to be hoped for from treatment. But there was always the possibility, when a source of infection had been surgically eradicated, that the meninges would be able to throw off the invaders. In all kinds of cases he believed much might be done by immuno-therapy—i.e., either by exhibiting sensitised vaccines or by transfusing blood from a person who had been immunised for the purpose. He believed some of the cases due to streptococci were helped to recovery by repeated lumbar puncture. He was convinced, from a good deal of research, that there were remarkably few mistakes made in the diagnosis of the condition; the chief difficulties were met with in early stages of the illness.

The Otological Aspect.

Sir WILLIAM MILLIGAN addressed himself to the otological aspect of the question. He said that of cases of meningitis in a general hospital, 5 to 6 per cent. were of otogenic, 1 to 2 per cent. of rhinogenic origin. Every septic invasion of the ear and its adnexa was liable to extension into the intracranial structures or into the general bloodstream. The rupture of a subdural cerebral or cerebellar abscess following a septic ear lesion might result in a profuse purulent infection of the subarachnoid or ventricular spaces. Of the complications, meningitis was the most difficult to recognise and the most important to be dealt with early. Sometimes in meningitis there was nothing to go upon for a few days beyond some rise in temperature, perhaps with a rigor; thereafter increased intracranial tension raised the alarm. In any suspicious case there should be free exposure of the middle ear cleft, tympanus, aditus, and mastoid antrum; and the removal of the area of infection would often of itself cause the removal of the threat of meningitis. In meningitis resulting from septic otitis media the blood- or lymph-stream are the usual modes of conveyance. Lumbar puncture, though the most convenient thing to do, he did not regard as necessarily the most reliable, as the "tap" was far from the disease focus, and the character of the fluid here was not necessarily the same as in the vicinity of the actual infection. The prognosis of serous meningitis was essentially good, always assuming that any primary focus of infection and any secondary intracranial lesion were eliminated. In purulent meningitis lumbar puncture should not be regarded as a means of securing drainage. In general, he considered that the higher the cell count in the cerebro-spinal fluid the greater was the likelihood of organisms being present in it. He had records of 39 cases of meningitis serosa in which recovery followed the elimination of the primary focus and tapping. The presence of viable organisms in the fluid rendered the prognosis infinitely worse than when only pus cells were found.

In actual practice three types of meningitis were met with: (1) Meningitis benigna or serosa; (2) meningitis semi-maligna; (3) meningitis maligna; and the gravity progressed in that ratio. The third group he regarded as an end-result of the second. The presence of dead organisms in the cerebro-spinal fluid he regarded as evidence that the tissue fluids of the patient were able to deal with the infection, and efficient drainage would probably effect cure. As the outlook was so vastly different, he thought every care should be taken to differentiate cases having organisms in the cerebro-spinal fluid from those in which they were absent from the fluid. The prospects of recovery depended on the patient's general power of resistance, the adequacy of the removal of the primary septic focus, and the success of drainage of the subarachnoid space and cisternæ. In bacterially-infected cases, lumbar puncture was not without danger, as blood infection might take place. Labyrinthitis, which was responsible for about 30 per cent. of cases of otitic meningitis, tended to mask the onset of the latter. There must be a more strict classification of cases of meningitis according to the pathological findings; it was a necessary step if more sufferers from this disease were to be saved.

The Neurological Point of View.

Dr. C. WORSTER-DROUGHT dealt with the neurological aspect of the subject, directing special attention to acute and subacute syphilitic meningitis. The meningo-vascular form of neuro-syphilis might develop within two or three months of the primary chancre, and it clinically closely resembled other forms of acute meningitis. In some such cases the onset was ushered in with headache and vomiting, and there were pyrexia, cervical rigidity, Kernig's sign, and occasionally strabismus. Only by examining the cerebro-spinal fluid could a diagnosis be arrived at. Usually that fluid was clear, but contained an excess of lymphocytes, and a positive Wassermann distinguished it from tuberculous meningitis. With treatment the prognosis was good. The cases of meningitis of oto-rhinological interest he had met with could be classified into four groups. In the first, the meningitis had followed intranasal operations, even such as submucous resection of the septum or removal of nasal polypi, the meningitic symptoms following 16 to 21 days after the operation. The cerebro-spinal fluid yielded usually the streptococcus, occasionally Pfeiffer's bacillus. The second group consisted of nasal or sinus disease where there had been no operation. When the sphenoidal sinus was involved, the organism was usually the pneumococcus. In the third group he placed cases of meningitis which followed wounds of the jaws. In those of the upper jaw, the meningitis arose from direct spread of the infection to the subarachnoid space, via nasal fossæ and sphenoidal sinus. In wounds of the lower jaw the meningitis was secondary to lung infection. A fourth class consisted of cases which were secondary to suppurative otitis media.

Among the symptoms which he had found of most use in diagnosis were pyrexia, headache (of increasing intensity), and vomiting. The most valuable of the physical signs, in his opinion, were rigidity of posterior cervical muscles, Kernig's sign, a fairly slow pulse associated with a high temperature, delirium or stupor with irritability, and tension or bulging of the anterior fontanelle in infants. The first of these he regarded as the earliest important sign.

Dr. Worster-Drought said that the treatment of all forms of non-tuberculous meningitis must include two principles: (1) Adequate drainage for the meningeal exudate; (2) the application of a specific immune serum in as close contact as possible with the inflamed tissues. The first he would bring about by repeated daily lumbar puncture. And puncture of the theca just below the seventh cervical vertebra he found safe, if the needle was inserted alone—i.e., without a stilette. If no fluid could be withdrawn at a lower level, puncture of the cisterna magna could be carried out; or, failing this, sphenoidal puncture, or puncture of the lateral ventricles. In otitic meningitis, trans-labyrinthine drainage was often successful.

The Pathological Diagnosis.

Dr. J. G. GREENFIELD said the laboratory diagnosis of meningitis was often very difficult, and the results of reactions performed in the laboratory must be interpreted clinically in the light of other facts. It was necessary to be very sure a cerebro-spinal fluid was normal in every way before it was safe to say meningitis in the patient was not imminent. If anything over 30 per cent. of the cells found in the fluid were polymorphonuclears, he regarded this as a danger signal. In very early meningitis the protein was often normal, yet hæmolysin and complement might be present; indeed, these latter two with a normal protein level he regarded as almost characteristic of early meningitis. The hæmolysis separately he regarded as rather treacherous, and said it was safer to test for the presence of complement only. Sometimes symptoms attributed to meningitis were due to uræmia. The cases which caused the greatest difficulty were those in which the fluid from a patient with little or no evidence of meningitis was turbid. This kind of fluid was particularly frequent in cases of empyema of the cranial air sinuses, and of abscess of brain resulting from them. He believed the pneumococcus always killed when it reached the subarachnoid space, similarly with the more virulent types of streptococcus. He believed the only clue as to whether a meningitis was generalised or not was that furnished by an estimation of the chloride percentage. Of nine cases of his own which recovered, in six the cerebro-spinal fluid was quite normal. Of seven who died from meningitis all had a fall of chlorides below 680 mg. before death. He had never known a case die from meningitis with the chlorides at their normal level. Every valuable test for the fluid should be used, and each specimen should be tested and estimated on its own merits.

Rhinogenic Meningitis.

Mr. W. M. MOLLISON dealt with the meningitis of rhinogenic origin, and said it occurred as a primary and sole complication of injury to the roof of the nose, as in fracture of the anterior fossa of the skull, involving the cribriform plate; but more often it was the sequel of some other intracranial complication of nasal disease, such as pachymeningitis, cerebral abscess, cavernous sinus thrombosis, or osteomyelitis of the frontal bone. He particularised the paths taken by (1) direct spread, (2) venous spread, (3) lymphatic spread. Katz and Blumenfeld had, he said, published figures showing the relative frequency with which infection of the various sinuses caused meningitis. In 67 cases it was the frontal sinus, in 7 the superior longitudinal sinus, in 6 the cavernous sinus, in 12 the ethmoid, in 31 the sphenoid, and in 25 there was thrombosis of the cavernous sinus. He said the number of intranasal operations must be large, but the number of cases of meningitis was small; much less than in aural cases. In some cases the onset of meningitis was delayed for months, as in a case related by Gregory, when the interval between an operation on the middle turbinals and the onset of meningitis was eight months. Almost every kind of intranasal operation had been followed by meningitis; in some cases plugging the nose for too long a time was responsible for the catastrophe. As a result of a questionnaire in America, 332 fatalities in the practice of specialists were reported, of which 125 were due to meningitis, and 120 of them followed nasal operations. Mr. Mollison related the leading features of a number of instructive cases in his own experience and among cases culled from the literature. He considered that treatment was of but little avail when once the disease had become established, especially when intranasal operation was the cause. The best defence treatment consisted in taking precautions against damage to the cribriform plate during operation, and in the observance of strict asepsis. Among the rules he suggested were the following: Never operate when the patient has an acute cold. If possible, open all pus-containing sinuses at one sitting. Do not plug for more than 12 hours. Deal gently, and avoid the olfactory sulcus.

Discussion.

Mr. W. STUART-LOW said it would be generally agreed that the great desideratum was prevention, and improvement in operative technique. Cases of meningitis were probably a reflection on the surgeon, but not entirely so. He laid great stress on the careful preparation of the patient for operation, seeing that nose, mouth, and ears were clean and free of disease. Mr. E. D. Davis had emphasised the importance of removing pus and debris from the ear by means of suction, and with this the speaker thoroughly agreed, for it gave a clean area to work in. After the operation he used aseptic horse serum; it was of a lower specific gravity than the blood and quickly started leucocytosis, which was an essential part of the healing process. He thought there was danger in lumbar puncture, particularly if frequently repeated.

Mr. SYDNEY SCOTT said that he had been much impressed by meeting with cases of meningitis in which there had been no indications of the condition until some days had elapsed; and when lumbar puncture was done, organisms were discovered in the fluid. This procedure should be carried out in all cases in which it seemed likely or possible that this might occur; also in every obscure case with a temperature in which there had been infection of ear or upper passages. He had never seen a case of streptococcal meningitis recover when repeated lumbar puncture had been neglected. He preferred to do it at 18, or 12-hourly intervals. He was able to recall quite ten cases which recovered after that had been carried out. He emphasised the importance of X ray examinations to detect ethmoidal and sphenoidal suppuration. Most of the operations which were followed by meningitis were either those on septic cavities, or in which cavities were opened with the object of reaching pus behind them. He agreed with Dr. Greenfield that when bacteria were absent from the cerebrospinal fluid, even if there was a high cell-content, the prognosis was good.

Dr. D. NABARRO also laid stress on the necessity of lumbar puncture in arriving at a diagnosis. He spoke of the value of urotropin in influenzal meningitis, and mentioned a case of the kind, under the late Dr. F. E. Batten, which recovered after that treatment. Dr. Batten administered 10 gr. every four hours during several days. He did not think any cases of pneumococcal meningitis recovered. A number of cases of meningitis started as a general septicæmia. Embolic foci occurred, and the ventricle might be the first part of the brain infected.

Dr. J. M. DICKSON (Edinburgh) spoke of the ventricular path of entry of micro-organisms in this disease. He said that in 100 post-mortem examinations on cases of meningitis, he was struck by the fact that in by far the majority the inflammatory action in the ventricles was in excess of the lesion on the surface of the brain. The distribution of the meningitis on the surface of the brain was just where the fluid in the inter-ventricular chain was near the surface. He also spoke of rare infections by paratyphoid and leptothrix organisms, as well as those of influenza. He had done post-mortem examinations on two cretins, both of whom died suddenly, and he found extensive meningitis. Dr. Gray and himself had practised immunotherapy with fairly good results in these cases, the serum from the patient himself sometimes being used.

The PRESIDENT, in concluding the debate, referred to the mutual help which these general discussions must bring, owing to the different angles and experiences from which the matter was viewed. He specially commended Dr. Greenfield's communication, and said it was probably from the clinical pathologist that most help in respect of this disease would probably come. Rigidity of neck muscles could not be regarded as an important diagnostic sign, as he had seen it of equal degree in children with acute rheumatism. There did not seem to have been much recent advance in treatment.

HARVEIAN SOCIETY OF LONDON.

A MEETING of this Society was held on Dec. 11th at the Paddington Town Hall, Dr. R. DUDFIELD, the President, in the chair.

Dr. CHARLES BUTTAR opened a discussion on the

Future Position of Consultants under the National Insurance Act.

He pointed out that the aim of the promoters of the National Health Insurance Act was to provide a medical service as closely resembling that of private practice as possible for those unable to pay adequate remuneration. But to the rich patient there still remained an advantage; he could walk down Harley-street and select a specialist at will. Therefore the addition of this privilege in some form or another was bound to be a feature of health insurance in the near future. The provision of a consultant service demanded some form of check on those serving, which meant a panel of consultants and a contract between them and the Government. Dr. Buttar defined a consultant as one who sees his patients in a consulting-room rather than a surgery, who specialises in a more or less limited branch of medicine, who receives the patients of other doctors, whose fees are greater than those of the general practitioner, whose time is to a considerable extent taken up by work performed gratuitously at a hospital, who often teaches and who frequently devotes part of his time to some kind of research. It was obvious that the insured person could not be allowed to roam at will down Harley-street, and therefore some kind of scheme must be worked out whereby the services of its inhabitants could be obtained by him. A number of problems for discussion immediately presented themselves, for instance: Would the panel consultant see his patients in his consulting-room, or in some apartment provided for him at a hospital? If he was required to call at the patient's house would he make some rule to the effect that the message must reach him before 10 A.M.? Would he receive the patient at his own request, or only in consultation with or at the request of his general practitioner? How would he arrange panel consultations so as not to clash with private appointments? And what provision would be made for the elaborate regulations and censure that might result from some slight mishap following his unpunctual attendance? What system of remuneration would he expect? It seemed obvious that no per capita fee would suit the case, the arrangement must be by attendance, or by some retaining fee, or both. Some limit must be settled for the fee for a visit, and attention must be paid to the question of how many miles he would go for that minimum fee.

Dr. Buttar supposed that the matter would be arranged somewhat on the lines of the venereal disease and tuberculosis clinics, and that it would be the younger consultants who would consent to serve. But there must be some limit to the number seen at a session; obvious difficulties were likely to arise from the overcrowding of the clinic of a popular consultant, while his colleague had scarcely any patients. The time would come when the consultant would be allotted by authority, but would the general practitioner then accept the opinion of an unselected consultant? And what would be the patient's attitude to this failure of the principle of free choice of doctor? And if he then sought other advice at a hospital, how would he be received? It seemed probable that the Government would compile a panel of specialists who would be willing to be called, and that this would consist mainly of the younger aspirants to consulting rank, or, in the provinces, of "glorified panel practitioners." The British Medical Association had laid down as the qualifications of a consultant that he should hold hospital appointments and have recent practice in the specialty in question, or that he should have followed special academic or post-graduate studies in that subject, or that it should be generally recognised by the practitioners of his area that he was proficient in that subject, the decision to rest with a local professional committee. Some such standard as this would be adopted as the panel criterion, and the consultant so chosen would consent to see a limited number of health insurance patients in a clinic session for a set fee, and to attend them at home when required for a given remuneration. The question of mileage fee would immediately arise, and presumably there would be some supervising authority in the nature of "referees." The patient attending such a clinic would be accompanied by his doctor or bear a letter from him, and the consultant would write to or see the doctor. The question of operative surgery did not seem clear; possibly the hospitals would admit such patients, but if the consultant had no beds in any hospital, what would then be done? The outlook seemed to be inevitably that of the *descensus averni* of nationalisation of the hospitals, and the nationalisation of medicine would surely follow unless the profession kept a wary eye on the situation. Unless the consultants prepared some system whereby State control would be avoided, the demand for a consulting service would increase to such an extent that a scheme would be organised and put into operation by somebody on which they were but inadequately represented.

Discussion.

Dr. W. **JAGGER** voiced the ignorance of the average consultant with regard to the working of the National Health Insurance system. The rural problem seemed to him to present very great difficulties. Who should decide which of the score or so of practitioners in a country area should be the consulting physician or surgeon of that district? He considered that younger consultants would be most unwise to undertake work of this nature; if they were to make their way they needed to spend all their time about the hospital to the staff of which they hoped in time to be appointed. He felt strongly that initiative was drowned in the State-paid official.

Dr. R. H. **DREAPER** agreed as to the difficulty which would probably be met with in provincial areas, and thought that there were no funds for consultant services in the approved societies' coffers, and that such a service was less popular with them than other proposed benefits such as the convalescent benefit. He pointed out that there was no difficulty about a consultant service in the working of the Metropolitan Asylums Board.

Dr. G. DE B. **TURTLE** drew attention to the Poor-law group of medical practitioners and institutions, and thought that their services and premises might well be used in this connexion. The voluntary hospitals had no accommodation for the reception of panel patients, but the Poor-law hospitals had such accommodation. He considered that the subject bristled with difficulties, but that the panel system was here to stay and must be accepted and made the best of. He urged more amalgamation all round, saying that the profession worked far too much in sections, and needed to get together to discuss such a difficult matter as this.

Dr. C. L. **TRAYLEN** said that he had never met a panel patient who had difficulty in obtaining a second opinion, and that the majority of them chose to see the consultant privately rather than attend a hospital; they were not so poor as the Government thought. He had been astonished at the wealthy patients who brought him panel cards, whereas a really poor patient, when told that the panel was for him as often as not replied: "Oh, is it? Well, I ain't a goin' to 'ave it!" What was needed was more organisation between the consultant and the general practitioner. He asked what arrangement would be made for the conveyance of patients who required an ambulance in country districts.

Mr. H. **TANNER** believed that if the panel had been worked out as suggested by the profession in the first instance many difficulties would never have appeared. The fact remained that a large section of the community could not pay full fees, and they must be treated somehow. The old club system, he said, was a disgrace, and there was no other system except some sort of contract, and the profession ought to set to work and draft some scheme where the element of compulsion did not enter. There were no objections to the purely professional work, only to the "red tape" regulations and interference and clerical work. The question was how such things could be got rid of when it was a question of public money. He foresaw that later on the State would take over the hospitals, and then the staff would be compelled to take panel patients.

Dr. S. **BOUSFIELD** referred to the reluctance on the part of younger consultants to take lower fees than experienced men for fear of lowering their dignity, and opined that they would not take on panel work any more than their seniors.

Mr. C. W. G. **BRYAN** said that one could not speak of a specialist in a country town in the same sense as in London. Out of some 20 practitioners there would have to be, perhaps, eight consultants! He thought that in London it would be relatively easy to get clinics going on the lines of the venereal disease clinics, but that they would not for long be staffed by the honorary staff; in a year or two the work would be done by aspirants, men holding posts as registrars and so on, and the patients would soon get to know that they were not being seen by the senior men, and would revert to the present system of attending hospitals as out-patients or seeing the consultant privately. There would be a further difficulty in the matter of beds for surgical operations. The junior men would be called out, not so much for their opinion as for their ability to send the patient into a hospital bed; the situation might then arise that the surgeon for the day would have to operate on a case which his junior had seen for a fee. The State would not tolerate the refusal of the hospital to admit such cases, and there would soon have to be State-controlled beds, thus producing an extremely difficult and disadvantageous condition of affairs leading directly on to State control of hospitals. Could not the profession intrude some voluntary scheme to avoid this?

Dr. A. H. **GOSSE** described a scheme now working smoothly at the Brompton Hospital, whereby the London County Council made a contribution to the cost of the hospital and had a right to two-thirds of the beds for its tuberculosis cases. When the scheme was initiated there was much misgiving as to the dangers of control, but for four years there had been no serious problem of interference, and no difficulty on either side. A London County Council official had the right to visit cases, but his function was really to secure continuity of treatment, and he did not interfere with the visiting staff. The London County Council made no conditions as to how the board of management used the grant given; they merely pointed out that the universal rule in the State was that if the State paid anyone they elected him. To avoid this control the hospital staff refused any honorarium from the grant.

Mr. W. G. BENDLE referred to the possible part that Poor-law institutions and officers might play, and said that at present the value of their work was considerably hampered by the operations of the existing Poor-law, which required revision, and that the institutions should be freed from the stigma of the name. He thought they might be used in some consultant service scheme.

The PRESIDENT thought that some attempt might well be made to bring the hospital services into the insurance service, as had been done at the Brompton Hospital, an area being given to each hospital for which it would act as consultant. In Paddington, St. Mary's Hospital was recognised in this way as the official consultant centre for tuberculosis, and to some extent this applied also to the maternity and child welfare service. He believed that if the hospitals made some offer such as this they might save themselves from State control. For rural areas the towns scattered about the country would be sufficient; almost any country area was now within motor distance of a town, and there was a Red Cross motor ambulance service available for transport. He was sanguine that the Poor-law service would take its place as a hospital and consultant centre, but not until the name had been changed and the problem of a medical service for the really poor transferred to the health authorities of the area.

HUNTERIAN SOCIETY.

A DINNER meeting of this Society was held at Simpson's Restaurant, Cheapside, London, on Dec. 15th, Mr. H. W. CARTER in the chair, when a discussion took place on

Headache.

Dr. C. O. HAWTHORNE opened the discussion from the medical standpoint. He said that when headache was a symptom, nothing less than a complete and comprehensive examination of the patient was adequate. It was not sufficient to find one condition which might be the cause. We must also assure ourselves that other causes were not present. Diagnosis meant a complete knowledge of the patient in both his positive and negative aspects. Headache might be due to general or local causes. Among the general causes were (*a*) chronic renal conditions, and (*b*) high blood pressure. Was the headache due to the quality of the blood, to the increased intracranial pressure, or to effusion into the substance of the membranes of the brain? The most prompt and efficacious method of treatment was blood-letting either by venesection or by leeches applied to the temple. Among the local causes of headache, tumour of the brain often had headache as its sole and unaccompanied symptom. An ophthalmoscopic examination of the patient was essential. The fundus would show with certainty the presence of intracranial tumours, but intracranial tumours might cause headache for weeks or months before a change took place in the fundus oculi, and therefore a single negative finding proved nothing. The examination must be repeated at frequent intervals, and could be carried out by the family physician. Where headache was due to intracranial tumour, optic neuritis and papillœdema might be seen, and similar symptoms were found in cases of intracranial abscess. He emphasised the fact that failure of vision occurred only after a lapse of weeks or months. Other gross intracranial conditions which caused headache were (*a*) intracranial syphilis, with its well-known nocturnal exacerbations of pain and insomnia; and (*b*) meningitis. He also stressed another method of examination—namely, lumbar puncture and examination of the cerebrospinal fluid. He mentioned three further local causes of headache which were rare, but were not to be neglected: (*a*) Suppuration in the sphenoidal sinus; (*b*) tabes dorsalis; and (*c*) cerebral attacks such as occurred sometimes in chlorotic women. Among eye conditions causing headache he mentioned (1) eyestrain, in which the headache was referred to the supraorbital region; (2) subacute iritis; (3) chronic glaucoma; and (4) migraine. He did not claim, however, that the latter was always due to ocular defects, and in its treatment diet was an important factor. There were three other vague conditions which might cause headache. These were (1) anæmia, (2) calcium defect, and (3) gastro-intestinal disturbances. For the treatment of the latter he recommended small doses of mercurial salts or pulv. rhei co. Headache might also be due to original sin, bad temper, or diplomacy.

Mr. W. TROTTER dealt with the subject from a surgical standpoint. He said that it was necessary to question closely as to what exactly the patient complained of, and certain forms of so-called headache could be dismissed on inquiry, such as (1) the neurotic headache, described by the patient as a "queer sensation" and not as pain; (2) a definite neuralgia; and (3) pain associated with disease of the accessory sinus of the nose which might be classified as not being true headache. This latter type tended to come on at a definite time of the day. True headache, he said, which was associated with a definite intracranial abnormality, was distinguished by pain behind the eyes of a throbbing character and was intensified by whatever stimulated circulation and increased intracranial tension. The surgeon had to deal with certain headaches in connexion with injury. Sometimes headache might immediately succeed an accident. In other cases it would not appear until the patient went about his work again. These headaches were due to the rigidity of the skull in preventing the circulation from re-establishing itself through the bruised part of the brain. Œdema due to trauma of the brain might persist for years, as cases had demonstrated. The practical points in diagnosing such headaches were the frequency of their occurrence and the characteristic clinical aspect of the cases. Treatment lay along the lines of prevention. The great majority of such headaches could be prevented by a rest in bed for a fortnight or three weeks after the trauma. If the headache persisted in spite of rest a decompression operation was performed.

Dr. BERNARD HART dealt with headaches as they occurred in the psychoneuroses, in hysteria, and neurasthenia. Headache in the psychoneuroses was a frequent feature. Its types and sites were legion. For example, helmet headache, clavus hystericus, bursting headache, and so forth. Three types must be distinguished: (1) where pain was present; (2) where abnormal sensations in the head were complained of (paræsthesia); and (3) where the patient described his sensations in a picturesque manner, which was often found in the psychasthenic type. In a certain number of headaches a psychological element gave rise to organic changes which produced pain. This was common in neurasthenia. Another group of headaches were unquestionably of pure psychogenetic origin, and could be produced under hypnosis. There was no such thing, he said, as an imaginary headache, for headache was a subjective symptom. In this second group the first subgroup were produced by suggestion and were seen typically in hysteria. In the second subgroup many cases could be mentioned. There was the pre-occupation type, where a headache which had once occurred became a psychological pre-occupation after objective causes had disappeared; and, again, there was the headache due to projection of incapacity, where the patient felt incapacity and projected it into his head, which thus became a subjective excuse for feelings of insufficiency. That was frequently the cause of paræsthesiæ. He considered that our knowledge that the brain was the organ of the mind was a factor in headache. He would be interested to compare headaches in a race which did not know that brain was the organ of the mind. The Freudians described elaborate chains of cause in functional cases of headache, but he thought many of these causation chains were unproven. Summarising his remarks, he said that various headaches fell into two broad groups: (1) the mediate group in which a psychic factor merely started the trouble; and (2) an immediate psychogenetic group, further subdivided into (*a*) the suggestion group, (*b*) the pre-occupation or projection of incapacity group. The distinction between the types was of great practical importance for treatment. In the first case psychotherapeutic measures were not of great value, but in the second psychotherapy was the approved treatment.

Dr. H. **FIELDEN BRIGGS** considered the subject from the dental aspect. He said that most headaches arising from teeth might be put into two headings: (1) reflex; and (2) toxic; and quoted several illustrative cases of both types. He explained at some length the value of trans-illumination by means of the Cameron lamp, and said that apical abscess might be a far greater cause of toxæmia than pyorrhœa, as no free drainage in the former was possible. He issued a warning against diagnosing disease of the teeth too readily, but stated that in his opinion many of the present-day dentifrices were doing harm by lowering the resistance of the gums. Pure salt and water and some chalk were all that were necessary for cleaning the teeth.

In the discussion which followed, Sir **JAMES DUNDAS-GRANT** referred to headaches in chlorotic women, and said that he had found chloride of ammonium to give good results in practice in this condition. He further mentioned that vertigo was a common symptom after trauma of the head, and he found that this symptom was often relieved by internal administration of perchloride of mercury. He thought calcium defect was a very important factor in causation.

Mr. C. P. **SYMONDS** mentioned two further types of headache: that due to neuritis, which was usually occipital and was accompanied by marked hyperæsthesia of the scalp; and that due to disease of the cranium, marked by persistent and aching pain.

Dr. **HALLS DALLY** cited an illustrative case where the patient had complained of persistent headache and the diagnosis was made by the blood film. The condition in this case was encephalitis lethargica.

Mr. **PHILIP FRANKLIN** referred to post-operative headache following operations on the nose, which was due to disturbance of bone. He said that a slight deviation of the septum or similar abnormality might cause great headache, although a patient with his nose full of polypi did not suffer.

Sir **BRUCE BRUCE-PORTER** referred to the dangers of diagnosing hysteria, and quoted two very interesting cases which had been so diagnosed and which proved after many years to be due to persistent œdema of the brain following trauma.

Mr. W. H. **KELSON** said that headaches in ear and nose trouble often meant retention of discharge, which was serious as meningitis might supervene.

Dr. **HOWARD HUMPHRIS** spoke of the value of electricity and electric light baths in headaches due to high blood pressure and to low blood pressure. For the former he used auto-condensation; for the latter static electricity. Artificial sunlight was of great benefit in calcium deficiency.

MANCHESTER MEDICAL SOCIETY.

A MEETING of this Society was held on Dec. 3rd, Prof. G. R. **MURRAY** in the chair, when a discussion was held on

Chronic Backache in Women.

Dr. E. **BOSDIN LEECH**, introducing the subject, excused himself for speaking of backache somewhat generally, as in only a few of the cases which he was called on to treat was the cause of the backache dependent on sex. He laid stress on conditions in which the duty of holding up the body was thrown on the voluntary nerve fibres to the back muscles, instead of on the postural nerves which caused a tonic contraction of the same muscles, and he suggested that over-use of the voluntary fibres in some way caused pain. This supposed over-use of voluntary nerve fibres might be due to maintaining the body in abnormal positions for which the postural fibres were not adapted, such as stooping while gardening; it might be due to mechanical body defects as in flat-foot, or to toxic conditions as in influenza, or merely to failure of the sympathetic fibres. He suggested that this failure might be the chief factor in neurotic backaches; just as we recognised sympathetic flushings as occurring in neuroses, so we might explain backache as a failure of the sympathetic supply. Cases of backache fell into two main groups according to whether the pain was one referred to the back from some other organ, or was a direct one caused by some lesion in the back itself. Usually the diagnosis between these two types was easy, owing to concomitant symptoms, but in cases of doubt an X ray photograph and careful examination of the mobility of the spine were essential, for such cases as telescoping of two vertebræ were not uncommon, and might easily be overlooked. He showed a skiagram in which the third lumbar vertebra of a patient who came for backache was much more opaque than any of the others, giving a dense clean-cut shadow among the normal ones above and below it. In this case there were signs of involvement of sacral nerves. Unfortunately no post-mortem examination was obtained when the patient died. The speaker doubted the value of back-pains of the dorsal region in the diagnosis of gastric ulcer and duodenal ulcer from each other and from other conditions. He had attempted to diagnose between such conditions by the position and nature of the pains in the back, but without definite success.

Dr. **DANIEL DOUGAL** then read a paper on the subject, which was published in full in THE LANCET of Dec. 13th (p. 1220).

The Sacro-Iliac Problem.

Mr. **HARRY PLATT** said that he would, appropriately, confine his share in the discussion to a survey of certain affections in which the symptomatology as a whole pointed to the existence of a lesion of the lower part of the spinal column or of the pelvic joints. The conditions which fell into this category were numerous, and they represented a variety of pathological changes. For clinical purposes they might be divided into three groups—a classification which had a purely utilitarian basis. 1. Traumatic lesions of the lumbar spine: (*a*) Strains—muscular or ligamentous; (*b*) fractures: crush fractures of the vertebral bodies, fractures of the transverse processes. 2. Chronic bone and joint lesions of the lumbar spine: (*a*) Tuberculosis (Pott's disease); syphilis; new growths. (*b*) Arthritis (spondylitis) of various types; osteo-arthritis; arthritis of infective origin—e.g., typhoid, gonorrhœa, &c.; spondylitis deformans. 3. Lesions of the sacro-iliac and lumbo-sacral articulations: (*a*) arthritis of various types—infective arthritis, tuberculous arthritis, &c.; (*b*) traumatic lesions—strains, acute and chronic; displacements (subluxations, dislocations); (*c*) "postural (static) strains" (defective balance). Most of the conditions included in groups 1 and 2 gave rise to a well-known clinical picture, which combined with the evidence obtained from a radiographic examination of the spine and pelvis led to the establishment of an accurate diagnosis without much difficulty. In these groups also the incidence of the various lesions in the two sexes was largely a matter of chance. But in the last group (group 3), he said, we were dealing with certain affections which were less well understood, although around the subject of derangements of the sacro-iliac joint there had accumulated a most extensive literature. It was of this group alone that he proposed to speak.

Mr. Platt then set forth in detail the anatomical structure of the sacro-iliac region, and proceeded to discuss the clinical aspects of the sacro-iliac problem. Our present-day knowledge, he said, we owed chiefly to American observers, and more particularly to the surgeons of the Boston School of Orthopædics, two of whom, in 1905 drew attention to a group of clinical signs which constituted a definite sacro-iliac syndrome, but indicative of non-destructive lesion of this joint. The more important features of this symptom-complex were: Backache, sciatic pain, lameness, tenderness in the region of the posterior inferior iliac spine and painful muscle spasm evolved by any movement or manipulation which tended to produce rocking of the innominate bone on the sacrum. Mr. Platt then gave an account of the work done on this problem in America, comparing it with that carried out in Great Britain, and discussed the various hypotheses which had been put forward in explaining the ætiology of the condition. His conclusions were as follows:—1. The sacro-iliac syndrome may be regarded as a definite clinical entity. Backache is a prominent feature in this symptom-complex. 2. The conditions which give rise to the sacro-iliac syndrome may be divided into two groups: (*a*) Traumatic strains of the sacro-iliac or lumbo-sacral articulations, and (*b*) postural or static strains unconnected with injury. 3. In the first group the term strain includes a variety of joint lesions such as are commonly seen in other joints when subjected to trauma. The symptoms evoked by injury may be perpetuated as a type of chronic sprain by the influence of postural factors. 4. The term postural or static sprain adequately describes the large number of patients who present the chronic sacro-iliac syndrome not induced by injury. In these it is unnecessary to postulate the existence of true sacro-iliac joint lesions. The backache is an expression of an undue stress thrown on the posterior musculature of the lower spine, buttocks, and thighs. In this group mild cases of spondylolisthesis are not infrequently encountered.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A meeting of this Society was held on Dec. 3rd, Sir David Wallace, the President, being in the chair. Prof. D. P. D. Wilkie read a paper on the

Surgery of the Biliary Passages.

He commenced by saying that considerable difficulty still existed as to the place of surgery in the treatment of biliary diseases; some declared that in the great majority of cases operation was the only rational treatment, while others were of the opinion that the risk was too great, and recommended expectant treatment. He stated there was no doubt as to the great frequency of the condition, and that the flatulent dyspepsia of the stout multiparous woman spelt cholecystitis and usually gall-stones. The paper was not to deal with symptomatology and diagnosis, but with the indications for operation, its risks and its benefits. Cholecystitis was by no means a benign condition, and he had been more and more impressed by the price that patients had to pay for neglected biliary diseases; the daily life was often crippled, and in many cases the condition proceeded to pancreatitis and malignant disease. The flatulent dyspeptic, breathless and languid after food, became unfit for physical exertion and increased in weight with further biliary stasis; in this way a vicious circle developed. Further, the increase of fat with toxic absorption caused breathlessness and palpitation, the "cholecystic heart," which was often followed by bronchial trouble, rendering the patient an unsuitable subject for operation. If the condition were left too long, it was quite likely that a lymphatic spread might occur, with the danger of acute or subacute pancreatitis as a complication. Stones in the ducts often caused patients to become chronic invalids, with recurrent attacks of cholangitis and fever. Jaundice was often not a marked feature, and the condition was often masked by pulmonary changes, and later secondary hepatic, pancreatic, and cardiac lesions increased the risk of or even prohibited operation. As these were the risks of expectant treatment, operation must be carefully considered. Gall-stones were never harmless.

Cases might be considered as to whether they were suitable or unsuitable for operation. Those demanding surgical interference included all cases of acute cholecystitis with obstruction of the duct by a calculus giving a tense, inflamed, and distended gall-bladder. In the young, one might delay operation for a short time in the hope of the attack subsiding, but in the elderly delay was dangerous. Other types of cases demanding operation were those of persistent flatulant dyspepsia punctuated by occasional attacks of acute cholecystitis, and those with recurrent cholangitis, rigors, and jaundice indicating a stone in the bile-duct. Operative measures should not be resorted to where other organic diseases were present, and especially in association with the following conditions: (*a*) myocardiac degeneration; (*b*) cirrhosis of the liver; (*c*) malignant disease of the pancreas; and (*d*) intense jaundice. In elderly bronchitic persons with acute cholecystitis, operation might be considered under "twilight sleep" and local anæsthesia. Cases in which operation was a subject for debate included those suffering from simple aseptic stone, with occasional sharp attacks of biliary colic. Operation is, on the whole, advisable in these cases, as trouble will probably come later. Attacks may often be warded off by removal of septic foci such as bad teeth.

Prof. Wilkie had based his paper on 197 consecutive cases operated on during the last five years. These were divided into five groups: (1) 29 urgent operations for acute cholecystitis; (2) 103 interval operations on the gall-bladder; (3) 32 common-duct cases; (4) 18 malignant cases; and (5) 15 cases with acute or subacute pancreatitis. 35 cases were definitely jaundiced. Of the 29 urgent cases, 8 were in males, 21 in females. In practically every case the cholecystitis was of the obstructive variety, with the gall-bladder inflamed and containing mucopus. In 27 cases gall-stones were present; in all cases the walls of the gall-bladder were diseased, and the organ would have been better removed, but in many cases peritonitis indicated evacuation and drainage as being more prudent. Cholecystectomy was performed in 13 cases. Of the 103 interval operations, 27 were in males, 76 in females. All cases showed thickening of the gall-bladder, gall-stones were present in 79, and sclerosis of the pancreas in 39. Where the gall-bladder constituted a functionless organ and a focus of infection it was removed; this happened in 47 cases. Where there was a good chance of recovery of function cholecystostomy was performed (56 cases). Unless the cystic duct could be seen and ligated under the eye, the gall-bladder was left. There were four deaths in this series. Of the 32 common bile-duct cases, 5 were males and 27 females. In 28 cases stones were found in the ducts varying in number. Eight cases had been operated on previously, but probably with inadequate exploration, and 17 cases were jaundiced at the time of operation. The stones when present were removed, the lumen of the duct explored, and drainage to the surface established, and if necessary removal (13 cases) or drainage (14 cases) of the gall-bladder was performed. In three cases cholecystectomy had previously been performed. There were four deaths. Of 18 malignant cases ten had carcinoma of the head of the pancreas, and the gall-bladder was anastomosed to the stomach or intestine; four died soon after operation, the others were relieved, two living as long as 12 months. In two cases of cancer of the common bile-duct free drainage was established. In six cases of carcinoma of the gall-bladder there was a history of long-standing gall-stones. In 15 cases of acute or subacute pancreatitis the patients had all suffered from long-standing cholecystitis; 13 were over 60 years of age. All were operated on for urgent symptoms. In five cases of hæmorrhagic pancreatitis there were four deaths, in ten subacute cases four died soon after operation, and in six the results were unsatisfactory.

Regarding the age of the patients, in cases of benign disease out of 32 patients over 60 years of age there was only one death. Jaundice was present at operation in 35 cases—in 17 due to stone in the duct, in 18 due to malignant disease. In all these glucose was given before and after operation. Hæmorrhage was met by intravenous injection of 10 per cent. calcium chloride in five cases, and intramuscular injection of 30 per cent. sodium citrate in ten cases. One of the former and two of the latter died. The sodium citrate seemed to have marked effect in lessening hæmorrhage. Concluding, Prof. Wilkie said that gall-stones and infection of the gall-bladder must be regarded seriously in view of their complications, and pointed out that the risk of operation in uncomplicated cases was slight.

In the discussion which followed Dr. W. T. Ritchie said he had observed some of the cases which had been described, and greatly favoured the sending of such cases early to the surgeon. The doubtful case for operation presented considerable difficulty, and many of the stout dyspeptic females could be kept in comparative comfort by medical treatment.—Sir Harold Stiles emphasised the importance of immediate operation in acute cases with regard to the stout person with intermittent attacks of biliary colic, preparation for operation by reduction of weight by 1 or 2 stones should be carried out, as this simplified the operation and reduced the risk of hernia. The ducts and pancreas should be freely exposed and examined in all cases. Discretion had to be exercised in many cases as to whether the gall-bladder should be removed or not. He agreed that sodium citrate was useful, and preferred it to calcium chloride.—Mr. J. W. Struthers raised the question whether gall-stones might cause symptoms simulating gastric ulcer. He believed in removing the gall-bladder to prevent possible recurrence of stones.—Mr. J. W. Dowden said he had recently met with five cases of gall-stones recurring after a previous operation. In one case carcinoma had developed.—Mr. Henry Wade said that in his pathological experience he had met with gall-stones in 10 per cent. of post mortems, indicating the frequency of the condition.

A communication was read by Dr. L. S. P. Davidson on

Anti-pneumococcal Immunity.

He stated that although for more than 40 years it had been known that a protective anti-pneumococcal serum could be prepared, this could not be used clinically till the types of pneumococci I., II., III., and IV. were discovered. It was then found that protective sera could be prepared only against Type I. In the Rockefeller Institute Type I. was found in 33 per cent. of cases, and had a mortality of 25 per cent. In 107 cases treated with immune serum the mortality was reduced to 7·5 per cent. This serum treatment had disadvantages to the general practitioner on account of its cost, the technical difficulties of its injection, the production of serum sickness, and through the necessity of coöperation with a bacteriological laboratory. Type identification of the pneumococcus by injection into a mouse and subsequent agglutinating reactions, could be carried out in 12 to 24 hours.

The proportion of cases of pneumonia in Edinburgh due to Type I. was found to differ throughout the year. In October and November 17 cases of pneumococcal infections all proved to be of Type I., while in 15 cases of acute lobar pneumonia in February and April 40 per cent. were of Type I. In both these periods, 17 cases of pneumococcal empyema all proved to be of Type I. These figures pointed to the possibility of considering serum therapy. Regarding serum therapy, the importance of preliminary laboratory investigation was emphasised. In the past, heat-killed cultures prepared in the form of a saline emulsion of micro-organisms were relied on, but recently detoxicated and defatted vaccines had been introduced.

He himself had previously carried out experiments with *B. suipestifer* as a test. This showed fixation of 5 units of complement with ordinary vaccines, and ½ unit with detoxicated vaccine, while defatted vaccine gave no result. The question was, What relation did antibodies bear to immunity? The real test of a vaccine was the production of immunity to a lethal dose of organisms. Tests on these lines were undertaken. Vaccines were made from a Type I. pneumococcus, (1) heat-killed vaccine, (2) detoxicated vaccine, (3) defatted vaccine. These were injected into rabbits, each receiving six doses with a five days' interval. After this, the serum of the rabbits was injected into mice together with a broth culture of pneumococcus, in addition Rockefeller immune serum, normal serum, and culture alone without serum were employed.

The general conclusion was that, judged by the production of antibodies and protection to lethal doses of the organism, detoxicated and defatted vaccines had no immunological value comparable to that of ordinary heat-killed vaccines.

In the discussion which followed, Prof. T. J. Mackie said that this work was only a part of Dr. Davidson's investigations. It was decisive and did not admit of criticism. The results were based on immunisation to actual lethal doses and not based on antibody formation.—Dr. H. Whitridge Davies said he had the opportunity of seeing cases of pneumonia in New York and was struck with the severity of the disease there as compared with that prevalent in this country.—Dr. Fergus Hewat agreed regarding the mortality from pneumonia in this country. recently 12 consecutive cases of acute pneumonia in one ward had all recovered. He questioned whether there was any need of serum. Since the war, he said, few typical cases of acute lobar pneumonia were to be seen.—Dr. W. T. Ritchie asked whether there was no clinical means of identifying the Type I. pneumococcus case. He also asked whether it was of advantage to perform lung puncture to procure the organism before sputum was available.

Dr. Davidson, in reply, agreed that the type of pneumonia in this country was not so severe as that in America. Serum treatment might still be useful in some cases and serum prepared from "ordinary" vaccines should be employed. In answer to questions he said there was no clinical means of identifying the Type I. pneumonia and that the laboratory investigation was the only means by which it could be diagnosed. Lung puncture he considered unnecessary as sufficient sputum could always be obtained even in the earliest cases, only a minute quantity being sufficient.

Exhibition of Clinical Cases.

Prof. D. Murray Lyon showed a case of *Cretinism* in a male aged 19. Treatment had been carried out for a week with some improvement. The patient was the size of a child of 5 and had the mentality of a child under 2. The upper part of the head was large, the skull base small, the whole body was stunted, the limbs stumpy, the hands and feet broad.

Dr. C. G. Lambie showed a case of *Syringobulbia* in a female aged 49. The patient, 16 years ago, had suffered from paralysis of the vocal cords; this had improved but had returned recently. At the present time there was paresis of the palate, tongue, and limbs, dissociation of sensation down to the second rib, nystagmus and a right extensor plantar reflex.

Reviews and Notices of Books.

PHYSICAL CHEMISTRY FOR STUDENTS OF MEDICINE.

By ALEXANDER FINDLAY, M.A., D.Sc., F.I.C., Professor of Chemistry, University of Aberdeen. London: Longmans, Green and Co. 1924. Pp. 227. 8*s*. 6*d*.

EACH of the main branches of scientific study to which the attention of the modern medical student must be applied, for example, physiology, pathology, and biochemistry, have attached to them a series of subsidiary subjects. Amongst the most important of these is physical chemistry, which hitherto has been taught in our medical schools as a kind of side line. There are signs that it will shortly have to occupy a much more important place in the curriculum of the doctor of the future. At present there is still a tendency to limit its study to that of a few stock questions dealt with at the end of the course, such as hydrogen-ion concentration, enzyme action, and colloids. The first is too often dismissed by harassed teachers with a few words on dissociation, the writing up on the board of the magic slogan $OH \times H = K$ (the meaning of which is not easy to expound), and a fleeting reference to pH. The second subject is disposed of by a reference to catalysts, whilst a summary of Graham's earlier experiments constitutes the stock lecture on modern theories of colloidal behaviour. This system, partly due to the small amount of time at the disposal of the lecturer, is to some extent perpetuated by examiners, who seem to expect replies based only upon such meagre grounding. The student at a hospital medical school is not, as a rule, conscious of the increasing importance of physical chemistry in medicine, and if he is, has hitherto been unable to find a book suited to his needs and early training.

Prof. Findlay has rendered a very great service to medical education in writing the present book. It is the first of its kind, and could hardly be improved upon. The author has appreciated the real difficulties of medical students, and has met them admirably. The volume is a complete text-book of physical chemistry, and, although quite advanced, is understandable by those without mathematical training. Chapter VIII., on the hydrion, serves as a typical example of the way in which the work is planned. Dissociation in solutions having been dealt with elsewhere, the author confines his remarks in this chapter to the determination of hydrogen-ion concentration. A brief description of solution pressure and electrode potential is given, together with a demonstration of the mathematical relations between E.M.F. and H-ion concentration. This leads up to the theory and use of the hydrogen electrode worked in conjunction with a potentiometer. A detailed account follows of the methods of calculating pH from the absolute concentration, and for converting pH back into C_H. In this respect the book appears to be unique in the English language (among works intended for medical libraries), for we have not found elsewhere an intelligible account of this simple expression. The indicator methods are next described, and the chapter concludes with the applications of what has gone before to the neutrality regulation of blood. Chapter X., again, concerns colloids. After the usual introductory matter, the author points out that there are many gradations between true and colloidal solutions depending upon the size of the particle, and that it is difficult to draw a sharp dividing line. Bechold's ultra-filtration methods, Brownian movement, osmotic pressure, and electric charges are discussed in great detail. The final chapter on adsorption is especially clear. There are a few references to papers of interest, and the diagrams are well executed.

On behalf of medical students and their teachers we are grateful to Prof. Findlay. Eminent "pure" chemists are often haughty as regards medical chemistry and look on it as something bastard and almost immoral.

THE INTERNAL SECRETION OF THE SEX GLANDS.

By ALEXANDER LIPSCHUTZ, Professor of Physiology in Dorpat University (Esthonia). Cambridge: W. Heffer and Sons, Ltd. 1924. Pp. 513. 21*s*.

THIS is perhaps the most comprehensive work on the subject that has yet appeared. As the author states in his preface, his original intention had been to bring out a revised translation of his book "Die Pubertätsdrüse und ihre Wirkungen" (Berne, 1919), but he found that so much valuable work had been done since the publication of his former treatise that his task really amounted to rewriting the whole subject. One has only to look at the bibliography and the references to foreign literature contained in his present work to realise how wide has been the author's review of the subject. The manuscript, originally written in English, has been carefully edited by Prof. F. H. A. Marshall, F.R.S. In its pages will be found a complete account of the endocrine functions of the gonads so far as these are known in all multicellular animals. Although the book is written from the point of view of the zoologist and the physiologist rather than that of the medical man there is much that will interest the medical profession. For example, it contains sections devoted to such subjects as eunuchoidism and sexual precocity, homosexuality, the influence of X rays on the testicle, the result of testicular grafting and of ligature of the vas, and the effect of the internal secretion of the sex glands on the pyschosexual behaviour of man. In the earlier part of the work, dealing with the function of the interstitial cells, the much debated point as to whether they are or are not the sole source of the internal secretion of the testes is considered at length. This subject has given rise to heated controversy, and it is satisfactory to read an account in which the subject is handled with such fairness. The author is, of course, in favour of the interstitial cells furnishing the internal secretion, although he agrees that more detailed histological investigations will be necessary in order to define in a stricter sense what kind of cells precisely are understood under the name of interstitial. He believes, however, that it is unjustifiable and arbitrary to declare that a tissue cannot be considered to have an endocrine function because it is "connective tissue." With this readers will agree, but at the same time it is impossible for anyone to go through the chapters dealing with this subject without being impressed by the complexity of the question and the large gaps in our knowledge that still exist.

In this book the medical man, the psychologist, and the student of eugenics will all find material of great importance to their studies. Although strictly scientific in its outlook it is not too technical for those who possess only a slight knowledge of psychology, and it should establish itself as a standard work on the subject.

CARDIOLOGY.

Les troubles fonctionnels du cœur. By R. LUTEMBACHER. Paris: Masson et Cie. 1924. Pp. 520. Fr.45.

IN this book, as its title indicates, the author has chosen as his text the functional derangement of the heart and its relation to disease of the heart muscle and valves. The arrhythmias are considered under two main headings—disturbances of excitability and disturbances of conductivity. Heart failure or asystole is treated as a disorder of contractility of the heart muscle, and the pain syndrome, of which angina pectoris is a type, is explained as an altered sensitivity of the heart peculiar to this organ. Many pages are given to the analysis and identification of functional disorders of the heart as they are recognised clinically. For this purpose the text is well illustrated by diagrams, polygraphic tracings, and electrocardiographic records. These are carefully selected, clearly printed for the most part, and conveniently placed. The author, in his use of the term hyperexcitability as a quality of heart muscle associated with certain types of irregular heart action, accepts without criticism a theory advanced by Prof. K. F. Wenckebach many years ago. It is true that the cardiac irregularities occurring in man are similar to those produced experimentally in animals. In the human subjects the irregularity is provoked by some natural process; in the animal an identical event may occur after an electrical or mechanical stimulus. It is possible to produce extra-systoles in a heart that has been poisoned by potassium chloride, when it is known that the excitability of the heart muscle has been lowered from the effects of the poison. We can also increase experimentally the excitability of the heart muscle without producing extra-systoles. Recent investigations have thrown very little light upon the association between structural disease and irregular heart action, apart from auricular fibrillation.

The book will be criticised from this point of view by those who know the work of Sir Thomas Lewis. The diagram given to illustrate circus movement in auricular fibrillation is confusing to the reader; it is a reminder of other theories advanced to explain the mechanism of this abnormal rhythm. In the chapter on heart failure, the author makes the classification seen in most text-books based on the back-pressure hypothesis. He attributes such symptoms as anginal pain and the breathlessness of cardiac asthma to left ventricular failure, and explains the signs which are associated with general venous engorgement to failure of the right heart to maintain the circulation. There was a time, not long ago, when the armchair philosopher could sit back and write an essay on heart failure, and no one could dispute the theories advanced to explain the functional derangement of the circulation. We have to-day in our possession many physiological facts which do not fit in with the theories of yesterday. The time has come when much of the cargo which text-books on diseases of the cardio-vascular system are carrying can be thrown overboard. If this is done, there will be less confusion in the minds of those who are struggling to understand the essentials of heart failure.

The chapter on treatment includes a good account of the pharmacological action of those drugs commonly employed in the treatment of diseases of the heart.

Ophthalmology.

Errors of Accommodation and Refraction of the Eye and Their Treatment. A Handbook for Students. Fifth edition. By Ernest Clarke, M.D., F.R.C.S., Consulting Surgeon to the Central London Ophthalmic Hospital, &c. London: Baillière, Tindall and Cox. 1924. Pp. 251. 8*s.* 6*d.*

This volume has undergone a thorough revision in its fifth edition and is well up to date; for example, the revised standards of vision tests for the public services received so recently as March, 1924, are included. It is well known that Mr. Clarke lays great stress on the accurate correction of the smallest errors of refraction in cases of astigmatism where any symptoms are present, working to eighths of a diopter in certain cases. For this purpose the use of a cycloplegic is essential up to the age of 45, but we note with pleasure that, whereas in previous editions atropine was recommended up to the age of 35, adult patients over 20 are now let off with homatropine, a considerable concession to their convenience. In the chapter on eyestrain the author returns to the subject of minute errors of refraction. "There is little doubt," he says, "that cataract may be started by the irregular contraction of the ciliary muscle in correcting low errors of astigmatism, and that the correction of these errors, with the consequent disappearance of the eyestrain, will stay the progress of this disease." If this were an established fact it would be one of great importance; the arguments in its favour, therefore, deserve a fuller exposition than is afforded by the somewhat cryptic statement quoted.

We welcome a new edition of a very useful work.

A Manual of Diseases of the Eye. Fifth edition. By Charles H. May, M.D. New York, Chief of the Eye Clinic, Columbia University, &c.; and Claud Worth, F.R.C.S. Eng., Consulting Surgeon to the Royal London Ophthalmic Hospital. London: Baillière, Tindall and Cox. 1924. With 337 figures and 22 coloured plates. Pp. 460. 15*s.*

This is a deservedly popular text-book, partly because of the excellent coloured plates which illustrate all the common anomalies of the eye. In the present edition many sections have been entirely rewritten, including the useful chapter by Mr. S. H. Browning on Vaccines in Ophthalmology. The chapters on squint and heterophoria are brief extracts from Claud Worth's larger book on Squint and incorporate his practical conclusions. That on Colour Vision was written by the late C. Devereux Marshall, who lost his life in the war, and it remains as he wrote it. It is an admirably clear and concise exposition of the theory of Edridge-Green; students should note, however, that for purposes of examination they will be expected to know something about the older theories which are here too briefly dismissed. The final chapter on visual requirements for public services has not been efficiently revised. It is not mentioned that the Edridge-Green lantern is now the official test for colour-blindness in the British Navy, and the Board of Trade tests for the British Mercantile Marine are quoted from old regulations, in which the Holmgren wools are still employed. In the methods used at present Holmgren's wools play no part; instead a lantern is employed (not available for general use) and there is provision for dark adaptation.

Die Tuberkulose des Auges. A Text-book for Practitioners and Specialists. By Dr. Arnold Löwenstein, Professor in the German University of Prague. Berlin and Vienna: Urban and Schwarzenberg. 1924. With 26 figures. Pp. 84. Gold marks 2.40.

Our knowledge of tuberculous affections of the eye is comparatively recent, and this book gives a good summary of the subject up to date. The section on tuberculosis of the iris, ciliary body, choroid, and retina, with the figures illustrating these conditions, mostly reproduced from other sources, are of great interest. The illustrations of tuberculous infiltration of the retinal veins, cases to which T. Axenfeld and W. Stock drew attention in 1909–11, deserve special notice. Of the tuberculous nature of phlyctenular disease there is not much new to be said, but the author gives evidence of its relation to tubercle, at any rate in the more severe cases. The greater part of the book is devoted to the discussion of therapeutic measures, and in this connexion great stress is laid on treatment by light. For conjunctival and lid affections the Finsen light is recommended. Much depends on the technique, and the good results that are quoted mostly come from the Finsen Institute at Copenhagen. For deeper affections an apparatus of Koeppe is described, by means of which appropriate portions of the spectrum (from 350 to 500 *μμ*) can be focused at different depths and its intensity regulated. Koeppe has reported more than 200 cases of tuberculous irido-cyclitis treated by this method, of which the great majority were cured in from two to six weeks. Some authorities rely more on general treatment by sun or artificial light than on local treatment, and the rapid healing of a tuberculous tear-sac under the general treatment is noted. A great part of the book is occupied by a discussion of specific treatment by tuberculin. A. v. Hippel claims a large proportion of cures from it. C. v. Hess, on the other hand, is sceptical of its effect. E. Schall and P. Stöwer believe that a considerable proportion of cases of detached retina have a tuberculous origin, and claim good results from tuberculin treatment. There is a consensus of opinion in favour of its use in cases of tuberculous irido-cyclitis. The question of dosage is discussed, and a synopsis of the literature of the subject is appended.

As a summary of the recent work of German-speaking authorities on the subject this little book is recommended.

THE PURPOSE OF EDUCATION.

Third edition. By ST. GEORGE LANE FOX PITT. Cambridge University Press. 1924. Pp. 92. 4s.

EDUCATION seemed simpler and plainer when we did not discuss it so much; when we took it for granted that it was a good thing that we had better get as much of as we could; when we drank our glass of milk instead of analysing it. The pendulum has swung a long way over to the other side now, and what with the "rights of children," the "necessity of self-expression," the "futility of mere book-knowledge" and such like jargon, the youth of the present day find excuse for inaction in the absorbing occupation of wondering what they are doing and why they are doing it. Appeals to opportunism and detailed argumentation are of little use in meeting such an outlook; faults of the spirit are not corrected by tales of the workhouse any more than by lurid pictures of a fiery hell, and the modern attempts at a Paley's evidences of education are no more convincing than their prototype. And it is the spirit of convinced belief in an ideal which teachers need to have, and to have in such abundance that it can overflow into their pupils. Mr. Pitt goes, we think, straight at the essential point when he simply and plainly argues that the purpose of education is to enable us to suppress our egoism and realise our necessary interdependence. Individual competition and its twin, the love of riches, are the more immediate blights under which the world suffers, and he urges uncompromisingly that we shall be always going wrong until "love one another" is the accepted and acknowledged aim of our education. It is well that these great propositions should be sometimes stated in explicit terms; no one doubts their essential truth, but they are apt to be mislaid and forgotten in the turmoil of eurhythmics and curricula. And the author leaves the details of their realisation to his readers, knowing that there are as many ways of educating well as there are of living well and that if the spirit is right the methods cannot go far wrong. The book is wonderfully cheap.

CHARLES BOUCHARD.

Un médecin philosophe: son œuvre et son temps. By PAUL LE GENDRE. Paris: Masson et Cie. 1924. Pp. 526. Fr.30.

THE portrait of Bouchard which forms the frontispiece to this account of him by an old friend will make a good many people say "He must have been an interesting man; I should like to have known him." And in Dr. Le Gendre's narrative they will find an attractive mixture of scholarship and affection which is an adequate commentary on the picture. Bouchard was born in 1837 and lived till 1915 the full and active life of a student who slowly passed up the narrow way prescribed in French education to be a great doctor and teacher. The 60 years of his manhood saw large changes in medicine and its allied sciences, and Dr. Le Gendre has made his subject the centre of what is really a history of French medicine during that period. He adds throughout the book little sketches of the men in contact with Bouchard as teachers, colleagues, or pupils; we learn, for example, that it was an attack of diphtheria which first took Sir Armand Ruffer, born at Lyons like Bouchard, and his brother-in-law, to Egypt to convalesce and so initiated his distinguished career as professor of pathology at the medical school and president of the sanitary board. In this and other ways we get an interesting view of Bouchard's surroundings as well as of himself, and the biography is a fine addition to the monument he left in the *Traité de pathologie générale* and the *Journal de physiologie et de pathologie générale*.

MATERIA MEDICA FOR NURSES.

A Text-book of Materia Medica for Nurses. Second edition. By A. L. MUIRHEAD, M.D., late Professor of Pharmacology, Creighton Medical College, Omaha, Nebraska; and EDITH P. BRODIE, A.B., R.N., Instructor in Materia Medica, St. Louis, Missouri. London: Henry Kimpton. 1924. Pp. 190. 10s. 6d.

THE term materia medica, as used in this book, comprises not only that subject in the narrower sense, but all that a nurse should know of drugs, pharmacology, therapeutics, and toxicology. In some few points this work does not correspond exactly to what is usually taught to nurses in England. We have noted that, in recent American nursing books on drugs, the calculation of doses and strengths, which in England is left to the dispenser, is explained as if the nurse were likely to compound the medicine. This Materia Medica devotes a section, though certainly not a large one, to such calculations. Another feature, not likely to be found in a nurses' text-book in England, is the presence of a number of respiratory and circulatory tracings, used to illustrate the action of drugs. These do not seem to add to the value of the book, since even for the initiated they are not all easy to follow. If they are retained in future editions the explanation of each figure should be much fuller than it is at present. On the whole the material in this book and the style of expression is excellent, while the printing, binding, and finish do credit to the publisher.

BIRKBECK COLLEGE.

1. *A Short History of Birkbeck College.* By C. DELISLE BURNS. London: University of London Press. 1924. Pp. 170. 5s.
2. *Birkbeck College Centenary Lectures, 1823–1923.* Same publishers. 1924. Pp. 178. 5s.

THESE two books form a worthy memorial of the centenary of Birkbeck College, an institution which after a stormy beginning and many difficulties has now settled down into the position of being a school of the University of London.

Birkbeck College began its career as a mechanics' institute, and was founded by Dr. George Birkbeck, after the model of a similar institution in Glasgow, to be a centre of popular education, not so much general, but one seeking to provide the working men of London with instruction in their own trades and to a certain extent in economics. Dr. Birkbeck was by no means a revolutionary, but much opposition was shown to the scheme in the press of the day. Absurd as were some of the objections the critics had some grounds for suspicion, seeing that one of the committee appointed to draw up a constitution for the proposed institute was the notable Francis Place, a root and branch radical, and incidentally one of the earliest pioneers in what is now known as birth control. Again, one of its ardent supporters was Brougham, an able man though perhaps somewhat unscrupulous. The committee was aware of the value of the printed word and founded a periodical called the *London Mechanics' Register*. The steps by which the London Mechanics' Institute grew into the Birkbeck Literary and Scientific Institution, and finally into Birkbeck College, can be traced in Mr. Burns's clearly written pages. Suffice it to say that the College has done, and continues to do, admirable work, and is a shining example of what a band of earnest students can accomplish, for unlike the older Universities which are governed by a guild of masters, Birkbeck College has always been in part at least governed by the students themselves.

The volume of centenary lectures, which has a preface by the late Prime Minister, Mr. Ramsay MacDonald, contains seven lectures dealing respectively with progress in philosophy, evolutionary economics, education in England, physical science, biology, and historical studies, and the work closes with the centenary oration delivered by the present Prime Minister, Mr. Stanley Baldwin. The three most interesting lectures from our point of view are those upon education, physical science, and biology, the authors being respectively Sir Michael Sadler, Sir Joseph Thomson, and Sir William Bateson. Mr. Baldwin's oration, which is not, as he himself says, an oration at all, is all the same a delightful composition, or, as he calls it, "a talk." It is simple and straightforward, full of shrewd remarks and common sense. His views upon the true republicanism of literature are illustrated by the remark that the man whose face lights up at any of four quotations which he gives is his brother. Here are the four:—

1. What makes him go sideways?
2. Golly, what a paper!
3. The light that never was on sea or land.
4. Where I dines I sleeps.

Men of middle or advanced middle age will be able to claim brotherhood with Mr. Baldwin; we are not so sure about a younger generation.

QUICK REFERENCE BOOK.

Lippincott's Quick Reference Book for Medicine and Surgery. Fourth edition, revised. By GEORGE E. REHBERGER, A.B., M.D. London: J. B. Lippincott Company. 1924. 65*s.*

THIS big book of well over 1000 pages, which, strange to say, are not numbered, has several striking features. The most astonishing fact about it is that it is the work of one man, a country practitioner of British Columbia, who in the first place collected the information for his own use, and later, when he determined to publish his notes, came east to systematise, with the aid of the libraries, what he had collected. It is divided into 11 sections; the first and largest deals with medicine and surgery, the next eight sections treat of various specialties, including orthopædics, and the last two treat of drugs. Each section is arranged alphabetically; cross references are very numerous and, on the whole, subjects are easily found. Recent work in research and in practice finds its place and the information given seems to be correct. A literary flavour is given to the book by the fact that the derivations of most of the terms used in medicine are set out; in some cases the desire to show the origin of words is carried unnecessarily far, as where the derivations of acute, chronic, dislocation, divergent, and presentation are inserted. The chief weakness of the book is exemplified in its pictures. Though these are well printed, too much is attempted in too small a space, so that they lack detail and do not convey to the mind the disease they are intended to represent. So in a milder degree is it with the text; there is not room for a full account of each subject and some are unduly compressed. Many country practitioners may prefer their old text-books, helped out by one of the numerous year books; others, however, may be well suited by the general review of medicine in all its branches given in this compendious volume.

THE MEDICAL REGISTER: UNTRACEABLE PRACTITIONERS IN 1924.

WE are requested by the Registrar of the General Medical Council to publish the following list of medical practitioners who have not replied to his inquiries as to the accuracy of their addresses. Anyone who finds his or her name included in this list should communicate immediately with the Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W. 1. Since this list was prepared a large number of further inquiries have been sent out, but it would be advisable that in all cases in which a practitioner's name appears in the list a communication should be addressed to the Registrar.

THE LANCET.

LONDON: SATURDAY, DECEMBER 20, 1924.

EPSOM COLLEGE.

IN the year within which we shall be living in less than a fortnight, Epsom College will reach its seventieth birthday, for the College was established as a public school, with a royal medical foundation, in 1855. It was founded by Dr. JOHN PROPERT with the intention of constituting a foundation for 50 boys, the children of medical men, where circumstances had precluded the boys from the opportunities usually enjoyed by the sons of the professional classes; the original terms of the foundation implied that the father should either be dead or be incapacitated from medical practice, though narrow pecuniary circumstances were within the terms of the benefits. QUEEN VICTORIA granted her patronage to the College at the outset, and subscriptions came in promptly, the movement receiving from the beginning the warmest support of THE LANCET whose proprietors sent £1000 in accordance with their words of encouragement. It will be seen that, save for the distinctive connexion with medicine, the foundation was moulded on that of Eton and Winchester, the best facilities for the education of the foundationers being provided, while a welcome was extended for the enjoyment of those facilities to the children of parents who were able to meet the ordinary public school charges.

The constitution of Epsom College is more exactly described in a letter which we publish this week from Dr. RAYMOND CRAWFURD, the chairman of the Council of the College, in an eloquent letter (see p. 1308) urging that with the approach of Christmas medical men should consider the grave claim upon their purses. The appeal of the College puts on them a responsibility to support it which every medical man should feel, wherever, even in the strenuous times we live in, he can discover a surplus. Dr CRAWFURD drives his appeal home with a quotation from the "Pervigilium Veneris," and the words of the unidentified poet make an apt motto for those who undertake to organise regular financial assistance from a body of subscribers. For they contain alike an encouragement to those who hitherto have not subscribed and an incitement to old subscribers to continue in well-doing. Such conduct is, of course, exactly what Epsom College requires from us—first a general spread of the movement among medical men, and secondly a regular persistence in their generosity from those who have already supported the movement. Epsom College has developed into a first-class public school, holding its own with other public schools in class-room and on playing-field, and supplying to the country men who obtain leading positions in public as well as in private life. From the minds of the public at large, as from the minds of many of the medical profession, the comparatively small eleemosynary establishment has tended to disappear; and this is natural, for the charitable activities of the work are strictly confined to the places where they are needed. But the prime reason of Epsom College should none the less always remain in the memory of the medical profession, and perusal of our advertisement columns this week will supply all the needful arguments for generosity.

It should never be forgotten that the greatest anxiety which the medical man may have is in regard to the education of his children. He pursues a profession which, in the majority of cases, and even after an extended period of practice, may not enable him to make large savings, for even in the more prominent walks of medicine the outgoings are apt to reach and maintain a dismal commensuration with the incomings. And thirdly, any incapacity to practise from whatever cause annuls professional receipts as effectually as death. The position of the medical man incapacitated or deeply impoverished while his children are at an expensive school age, and equally the position of the widow of a medical man dying before any opportunity of saving has occurred, is a particularly pathetic one in regard to the children. In such events a foundationership at Epsom College utterly changes for good the whole prospects not only of the boy who is helped —that must always be so—but in many cases of the whole family, the relief from one heavy charge enabling difficulties in other directions to be met bravely and practically. In the spirit of Dr. CRAWFURD's quotation we would urge upon all subscribers to Epsom College to continue and, where possible, enlarge their support, and upon all our readers, who are not yet supporters of the foundation, to set the situation right.

◆

BACKACHE.

PAIN or aching in the back is a common symptom. It is due to a diversity of causes and takes an equal variety of forms. Several considerations suggest themselves to account for this ætiological and symptomatic complexity: the actual extent of the dorsal superficies, the fact that the back is part of the two great cavities of the body, thoracic and abdominal; the subjacent spinal column in its whole length; the spinal cord within the latter, and the emergence at regular intervals of spinal roots which radiate in part at least through dorsal tissues. Still another consideration is not without significance; the individual is unable to see his own back, which remains a sort of terra incognita to him, explorable only by the diagnostic finger and the abode of mischief-makers that escape his observation. Sir JOHN COLLIE says that pain in the back is the most common element in claims for compensation which are litigated in the courts; he cites the sage advice of the injured workman's "pal"—"When you get hurt, say it's yer back; the doctors can't never get round yer back."

Only by systematising our methods of investigation and our conceptions of ætiology can we hope to steer our course successfully through this wide symptomatological sea. We must not take as our pilot the gynæcologist only, or the orthopædist, or the neurologist, or the internist; rather should the practitioner familiarise himself with the features of the dorsal chart, and trace his way himself. A first rule should be observed unvaryingly; he must ascertain to the best of his ability whether the site of the disorder originating the pain is in the central nervous system or outside it. In respect of the former it is important to bear in mind that many organic diseases of the spinal cord are unaccompanied by pain, both in acute and chronic stages; unfortunately there are exceptions, since irritation of the meninges and consequent root pains occasionally develop in the initial period, for example, of so ordinarily painless a condition as poliomyelitis anterior acuta. "Central" pains, as they have been somewhat loosely called, may be a feature of such cord diseases as syringomyelia or disseminated sclerosis; they are usually referred to some segmental distribution in trunk, back, or limbs. Speaking generally, however, organic spinal cord disease is rarely per se a cause of backache or back pains, while in any case it is commonly diagnosable by symptoms and signs belonging to another category altogether. The case is different in regard to any morbid process implicating meninges, posterior root ganglia, and posterior roots; irritation by inflammation or compression is a potent cause of pains in the back, yet luckily these are always more or less characteristic; they have a topographic signature capable of being read by anyone with knowledge of spinal segmentation. The girdle pains of tabes dorsalis, the unilateral radiation of herpetic neuralgia, of intercostal neuralgia, the root pains of an extramedullary or extrathecal spinal tumour, and so on, sufficiently illustrate the point. It is well not to lose sight of the fact, however, that such radicular neuralgias frequently settle in the periphery of the cutaneous segment or segments involved, and may therefore, on ocassion, be pseudabdominal or pseudo-thoracic; sometimes, also, there is a double pain area, back and front, in the particular root zone concerned. Still confining attention to organic disease of the central nervous system, we may point out that pain limited roughly to the midline of the back, that is, non-segmental, is of infrequent occurrence but deserves passing notice; pain in the back of the neck sometimes accompanies intracranial tumours and is a useful corroborative symptom; diffuse back pain is occasionally found with perithecal spinal tumours, the patient preferring to lie on his side; the neck and back pains of varieties of meningitis may not be combined with any definite radicular spread.

It is when nervous disease in the stricter sense is excluded that the practitioner confronted with a case of backache must needs exhibit the *flair* of the ferret and the wisdom of the savant. Two medical societies have lately[1] set apart whole evenings to consider this aspect of backache. Truly, there is a certain fascination in trailing so elusive a symptom to its lair in bone, muscle, or viscus, or, for that matter, in the world of mental images and unconscious motives. The principles which should guide him in his search are more important than their application in detail, but there is no thesaurus of knowledge in the textbooks; each must work out a scheme for himself, basing it on information derived from personal clinical study or unwittingly absorbed as he reads, or inculcated by some favourite teacher who has himself, it may be, done little else than hand on the torch of bedside skill and acumen. For the student it is true there are charts or maps of the sites of dolor dorsi to be found in various works on the subject, compiled from different sources, and embodying useful considerations, but nothing can take the place of that clinical insight which is compounded of knowledge of human material and of interpretative instinct. The physician has first to decide whether the back pain is genuine or not; that is to say, he must from his general impressions and from the patient's behaviour, tenor, and response to his tests come to a conclusion on the all-important question whether it has a basis in pathological fact or in psycho-pathological fiction (as the materialistically minded may be tempted to place pains that have no recognisable structural origin). To aid him in this respect he must consider the apparent seat of the pain, its variability or otherwise, its extent and intensity, its relation to known anatomical structures, its modifications with pressure, change of position, light touches, its connexion with spinal mobility, its relative depth from the surface; he must at the same time keep steadily before him the possibility of reference of visceral pain, thoracic or abdominal, and of its being but a local manifestation of a general constitutional toxic or toxæmic state. Notwithstanding the manifold difficulties a surprising degree of diagnostic accuracy may often be attained. Pain that radiates from occiput to coccyx or localises itself in more than one region of the spine is much less likely to be organic than hysterical or neurasthenic; even toxic pains, such as those of rheumatism or small-pox, are curiously apt to present but one dorsal seat. Ligamentous, tendinous, fibrous, muscular neuralgias may similarly exhibit a peculiarly local character, as does that of so-called sacro-iliac disease, and if we are to credit the manipulative surgeon, minor spinous articular displacements can be detected by the limited and confined nature of the pain caused thereby. The more serious morbid changes associated with caries and malignant vertebral disease rarely offer room for diagnostic confusion; relative rarities such as tabetic spinal arthropathies, or the typhoid spine, can be recognised more readily than their infrequency might lead one to suppose. As for the large group of referred back pains, the shoulder pains of splenic and liver involvement, of diaphragmatic pleurisy, the lumbar pains of renal disease and uterine disorders, and many more that cannot now be specified, the practitioner must learn by experience the character and the region of the aching complained of, and thus render himself independent of artificial aids to diagnosis. Knowledge of this kind is worth everything to him.

Even with this abundance of ætiological and symptomatic data the matter is far from being exhausted. The student should beware of limiting the range of his vision to the back itself, otherwise he will neglect the aching caused by static leg and foot errors and other factors in muscular imbalance; he will ascertain the occupation of his patient, remembering the "tired backs" of many trades and avocations, of the school girl as well as of the microscopist; he will notice anæmia or chlorosis, and will not miss an attack of influenza or an incipient pneumonia by failing to use his clinical thermometer. In evaluating the significance of backache in the obvious neuropath he will remind himself of the proneness of the lay mind to make its own subdivision of the dorsal regions; the vertebra prominens, and the coccyx, can be felt by the ignorant and become the seat of dynias or topoalgias that have no objective foundation.

◆

THE PRESENT NEEDS OF PSYCHIATRY.

WHILE the Royal Commission is still sitting and taking evidence it is appropriate to consider the many directions in which the theory and practice of psychiatry is in need of help. In his presidential address to this year's annual meeting of the Medico-Psychological Association, which is now available to the general reader,[1] Dr. M. J. NOLAN dealt with present-day advances in what may be termed the science of medicine, and of psychiatry in particular, in their relation to the actual treatment of the insane. Although, as Dr. NOLAN indicates, a great volume of potentially useful data is accumulating, it must be confessed that research has as yet afforded no clue to the pathogenesis of mental disease as a whole. Senile dementia, general paralysis, and other conditions due to gross structural changes, we may be said to understand, but is there a single type of insanity from which patients commonly (and we must admit, spontaneously) recover, apart perhaps from those caused by external poisons, whose origins and mechanism we can claim to have elucidated? There is, perhaps, a danger, which has certainly a formidable parallel in the field of general medicine, that the advance of psychiatry may be supposed too exclusively to depend on laboratory investigations.

---

[1] Journal of Mental Science, October, 1924.

That sympathetic clinical observation must remain indispensable is the lesson of these words from Dr. NOLAN'S address. "At the moment the call in general medical education in America is 'back to the bedside,' as it is felt that 'however perfect the knowledge of disease may be, it is practically useless without the study of the patient also.' I would strongly urge those who, situated as I am, are precluded from the fascinating methods of laboratory research, to be content to read with as full an understanding as possible, the human documents that come within their ken, and to bring to bear on them the interpretations of the best and most practicable findings in general medicine, in psychopathology, in Christian Science, in faith-healing, in psychotherapy and occupation therapy, using anything which may prove of benefit in a particular case." . . . "Thought is life, even when disturbed in function to a pathological degree: the cause of the disturbance is more likely to be discovered by and in a living mind than by the sole observation of dead matter." Although the psychogenic school will subscribe, perhaps, more heartily than the physiogenic to this exordium, it will be generally admitted that the advantages of knowing your patient at present far outweigh any benefits which can be attained by the adoption of a laboratory standpoint.

In the Dominions perhaps more than in this country the primary need may be a comprehensive survey of the problem of mental disease as it presents itself locally. The Commissioner for Mental Hygiene for the Union of South Africa recently concluded a tour of Europe and America, taken with the purpose of studying methods of dealing with mental disorder in other countries. It may well be imagined that, should he be given a free hand, the practical result of this survey should be as good a system for South Africa as prevails anywhere. His constant criticism of the practice prevailing in other countries is directed at the lack of coördination between the numerous authorities concerned, and in some of this one can readily conceive that a study of British methods of dealing with mental deficiency has prompted his observations. Steps are being taken to ascertain the magnitude of the problem in South Africa, and the requirements under different heads, especially that of mental deficiency. The outline of the organisation which it is proposed to set up centres on a primary medical referee, whose business it shall be to delegate cases to suitable institutions. The scheme covers not only insanity and mental deficiency in their broader aspects, but child welfare, delinquency, crime, and all those branches of civil administration and social work in which the services of the alienist are being employed to an increasing extent, particularly in America. It is evident that hitherto efforts in this direction in South Africa have been only sporadic. It may be gathered from the Commissioner's very frank report that the South African asylums are at present grossly overcrowded, and that there is a shortage of candidates for the medical staff (recently qualified medical graduates in Great Britain might take note), and for the higher posts in the nursing service. The incidence of certified insanity is 20 per 10,000 in South Africa, as against an average of 40 per 10,000 in European countries, but the Commissioner has no reason to believe that the numbers actually requiring treatment are less. There are, he writes, many people in South Africa who, but for the sparsity of the population and consequent lack of opportunity to betray their social or anti-social qualities, would be considered so mentally disordered that in a denser population they would be committed to a mental hospital. There is welcome evidence in the report as a whole that the problems afforded by mental disease in South Africa are being attacked as they are revealed with unexampled vigour.

At home the need for putting the available knowledge of mental disease at the disposal of those who can profit by it is at last receiving some attention, and to many important aspects of the subject Dr. EDWIN GOODALL, medical superintendent of the Cardiff City Mental Hospital, calls attention in our columns this week (p. 1273). Further, an intensive course of instruction, lasting one week, was recently held at the Maudsley Hospital for those engaged in various branches of social work. It was organised by the Central Association for Mental Welfare and given under the direction of Dr. EDWARD MAPOTHER, the medical superintendent of the hospital. The course was attended by over 50 workers from all parts of the country representing extremely varied branches of social activity. Naturally, in large part they were those whose work is intimately connected with mental disorder and deficiency, and these included in addition many of the county secretaries of the Central Association for Mental Welfare, representatives of the Board of Control, and various lay officials in charge of institutions and other arrangements. But perhaps even more significant as indicating the growing recognition of the importance of these problems was the presence of many whose work is less specially associated with them. Among such were persons representing county councils, Poor-law guardians, the Charity Organisation Society, the almoners of several of the main London hospitals. Probably there is no one whose work brings him closely into contact with mental disorders who requires convincing as to the necessity for drastic reconstruction, but whether this Commission will be fruitful will certainly in large part depend on the existence of an instructed public, not one ready to rest content with mere depreciation of those struggling to do their best under difficult conditions, but rather one aware of the real defects and requirements. Every attempt was made to stress these points in the recent course, and apart from its strictly practical value to those attending, a useful function of such a course is the creation of numerous foci of accurate information.

Annotations.

"Ne quid nimis."

ENDOCRINE THERAPY IN SENILE CONDITIONS.

GERIATRICS now have their own literature, but it remains true that the pathology of the aged is not as well known as it should be. On the scientific side, although in a large measure forming part of the picture of ordinary pathology, old age has its own peculiar aspects which stand apart from ordinary morbid syndromes and are deserving of special study; from the practical side the neglect may be due to the atmosphere of indifference and antipathy which frequently surrounds old people. Of this familial lack of interest the doctor is sometimes the accomplice, and either from indolence or lack of goodwill considers the diseases of old age as something necessary and irreparable for which nothing can be done, explaining every morbid syndrome by the convenient diagnosis of "senility" without adequate investigation, and restricting himself to the treatment of symptoms alone. Well worthy of study is the remarkable physical well-being and mental lucidity which many old people retain even beyond 80 years of age—their resistance to certain maladies, their relative immunity to some morbid infections, and the relatively benign attitude which certain serious diseases assume in them, such as tuberculosis and epithelial tumours. The arterio-sclerosis itself, which in its multiple anatomical lesions and clinical forms dominates the pathology of the old, assumes in them a very chronic process, and, if it causes slow deterioration of every function, it usually does so in a manner so harmonious and gradual as to allow a definite degree of mental and bodily activity even in individuals who at death show very advanced atheromatous lesions. This is in contrast to the arterio-sclerosis of middle age, allied to such toxic factors as alcoholism and syphilis which presents a very different and more serious clinical aspect. Senile arterio-sclerosis is within certain limits amenable to treatment, and much may be done to improve the condition of old persons who even if ill are far from being incurable.

Falta described a multiple sclerosis of the endocrine glands, and it is probable that many senile troubles are bound up with disorders in endocrine function of atheromatous origin. If this be admitted the rational administration of opotherapic preparations should ameliorate some of the ills of old people.

Such is the gist of the opinions held by Dr. Ugo Daretti of Rome, and published in a recent Italian periodical,[1] together with an account of eight cases of old women who, though of advanced age, were free from paralysis, paresis, renal or pancreatic lesions clinically demonstrable, but who, although enjoying a fair amount of healthy activity, complained of headaches, slight giddiness, insomnia, mental depression, gastric and intestinal dyspepsia, obstinate constipation, and rheumatic pains. These patients were put under treatment with extracts of ovary, suprarenal and thyroid, for a period of three months with the following results. In five there was very distinct improvement in all the symptoms with some reduction of blood pressure, in two a slight improvement, and in the remaining case none except relief to constipation. It is difficult to interpret in detail the clinical disturbances observed in each case, and to divide the pathological responsibility for them between sclerosis of the various arterial regions and endocrine insufficiency, either pluriglandular or of single hormonopoietic groups. It would be still more arduous to attempt an interpretation of the therapeutic advantages obtained and to differentiate the good effects that the opotherapic agent may have produced, probably by a hypotensive mechanism, on the atheromatous lesions from those directed to endocrine insufficiency. But the cases reported by Dr. Daretti seem to show that the administration of endocrine glands in cases of senile arterio-sclerosis may give definite and interesting results, improving the general condition, lessening the arterial syndrome, and especially influencing beneficially the dyspeptic troubles and obstinate constipation of the aged.

KALA-AZAR.

KALA-AZAR is a disease of which little is heard outside India, but in that country, especially in Assam, it is a real scourge. It has advanced relentlessly up the Brahmaputra Valley, 300 miles in the last 30 years, culminating in the Nowgong district, where the population was greatly reduced in the last decade of the nineteenth century with a death-rate of 90 per cent. It was common for two-thirds of the villagers to be carried off, while extensive areas of land fell out of cultivation and became thereby valueless. The story of kala-azar in Assam has already been exhaustively treated by Sir Leonard Rogers, and his work has been taken up and extended by Colonel McCombie Young,[2] who has recently published an account of his efforts during the last 14 years. The period of his experience of kala-azar has been definitely divided by two phases of its manifestations—a period of quiescence following the epidemic decades of the 'eighties and 'nineties, and a more recent phase of widespread recrudescence—the present period of activity being an aftermath of the influenza pandemic. The period of recrudescence appears to follow on a succession of unhealthy seasons, as Rogers first suggested. The Government of Assam has maintained a special staff for combating the disease and the Sanitary Department has fully justified its existence. The survey of 1912–13 showed that the disease remained endemic in certain areas and had persisted as glowing embers in the old track of the epidemic fires. This treatise, which is illustrated by statistical tables, deals successively with the influence of kala-azar on the growth of the population and a description of the preventive measures taken during the quiescent period. The removal of infected families and their contacts from infected sites was so successful that in 1916 the opinion was expressed that in a year or two the extinction of the disease in the Golaghat district might be expected, but the great influenza epidemic changed the whole situation. The general recrudescence led to the adoption of compulsory treatment by intravenous injection of tartar emetic on a large scale as the chief preventive operation. The harrowing sights seen in the pre-treatment days are graphically described—the deserted villages, the abandoned dying, the terribly emaciated survivors. The remainder of the volume deals with the encouraging results of compulsory treatment, the practical methods adopted in carrying it out, concluding with a description of the clinical types of the disease and of the preventive operations undertaken on tea estates. The publication should serve as an incentive to research workers to try to fill in the blanks in our knowledge of kala-azar.

SENSITISED VACCINE.

THE best way of provoking the tissues of the body to develop their protective powers is still far from settled. The remarks of Dr. L. S. P. Davidson at the Edinburgh Medico-Chirurgical Society (p. 1288) on the relative value of different vaccines command attention. That antigen combined with and therefore presumably neutralised by its specific antibody should prove to be more efficacious in the production of immunity than plain antigen has always been something of a puzzle to laboratory workers. In Japan, where apparently the sensitised variety of vaccine still holds sway, the matter has recently received serious attention from the laboratory standpoint. Using sensitised ox corpuscles injected into rabbits, Hjima, working in the Government Institute for Infectious Diseases, has found that they were practically incapable of giving rise to the production of antibody. Immediately after their injection he was able to demonstrate small quantities of immune body in the serum, but this he believed to be due to dissociation of some of the injected antibody from the antigen. His results led him to the general conclusion that "sensitisation of antigen is no less than its neutralisation." The fact that other workers have in the past found sensitised antigen to be active in the production of antibody he believes to be due to lack of appreciation of the time and of the amount of immune body required for complete saturation of the antigen. A further interesting result of his work was the demonstration of the fact that injection of sensitised antigen is followed by a sudden and striking drop in the "complement" of the circulating blood of the injected animal—due apparently to its becoming linked up to the sensitised antigen. Full dosage with a sensitised vaccine may, according to these results, be looked upon as an excellent method for the reduction of the complemental power of the circulating blood without in any way increasing the specific immune body—a consummation hardly to be desired.

DOCTORS' FEES AT INQUESTS.

THE dissatisfaction which has arisen at the recent decision of the L.C.C. to disallow inquest fees to medical officers of certain institutions was voiced at last week's meeting of the Council, when questions on the subject were addressed to Mr. Cyril H. M. Jacobs, Chairman of the Public Control Committee. We reproduce the questions and answers verbatim.

Mr. J. D. Gilbert asked: (1) What is the scale of allowances made by the Council to doctors who give evidence before coroners at inquests?—Mr. Jacobs replied: Section 22 of the Coroners Act, 1887, provides for the payment of a fee of £1 1s. for giving evidence at an inquest and £2 2s. if, in addition, a *post-mortem* examination is made. Sub-section 2 of Section 22 provides that such fees are not payable to certain doctors, such as hospital doctors, &c.

Mr. Gilbert asked: Is there not great dissatisfaction on the part of hospital doctors at the scale of allowances, and is he aware that at a recent inquest a doctor refused an allowance of 2*d.* offered him by the coroner and allowed by the Council?—Mr. Jacobs replied: As a result of representations made by the Government auditor, the Council on July 29th, 1924, decided that, as from Sept. 1st, 1924, the payment of inquest fees should be discontinued to medical officers of hospitals controlled by the Metropolitan Asylums Board, workhouses, Poor-law infirmaries, general infirmaries, prisons, and other medical institutions of a public character. It is a fact that there has been a considerable amount of dissatisfaction on the part of those doctors who previously received fees, and I am aware of the incident mentioned. The Council's schedule of disbursements at an inquest permits the payment of actual travelling expenses, not exceeding 2*s.* 6*d.*, to those medical witnesses who are not paid the above-mentioned fees.

[2] Kala-Azar in Assam. An Account of the Preventive Operations, 1910 to 1923, and Notes on the Epidemiology of the Disease in Assam and India. By Lt.-Col. T. C. McCombie Young, I.M.S., M.D., D.P.H., late Director of Public Health, Assam. With a foreword by Sir Leonard Rogers, C.I.E., M.D., F.R.S., I.M.S. (retired).

Mr. Jacobs added that before any alteration of the present practice could be made an amendment of the law was necessary.

POST-OPERATIVE EMBOLISM.

IN the current issue of *Surgery, Gynecology, and Obstetrics* (p. 421) Dr. E. C. Mason of Detroit records the results of his experimental inquiry undertaken into the production and prevention of thrombosis and pulmonary embolism. Dr. Mason found that he was able to produce very rapid coagulation of the blood in the living animal by the intravenous injection of small quantities of a saline extract of dried tissue. The intravascular clots produced by this means showed the lamination and other features characteristic of thrombi formed during life. By bringing about clotting of the contained blood in the temporarily occluded jugular vein by injection of the tissue extract and then releasing the clot into the general circulation, he was furthermore able to procure pulmonary embolism, fatal or otherwise, according to the amount of extract injected. His results led him to the conclusion that tissue extract is a most active agent in promoting the coagulation of the blood. With a preparation of a phosphatide isolated from the liver by Howell, he found that he was able to neutralise completely the coagulant effect of the tissue extract. On the assumption that the original thrombus, dislodgment of portions of which gives rise to pulmonary embolism, is produced at or shortly after the operation—an assumption which would not be universally granted—he suggests that injection of such a preparation at the time of the operation would do away with the risk of subsequent pulmonary embolism.

NATURE OR NURTURE?

THE relative value of heredity and environment in the formation of the child's character and career is a matter of profound and far-reaching importance for mankind. Whether the problem can be solved or not it is immensely worth discussion. As Mr. C. V. Drysdale, D.Sc., pointed out last week at a meeting of the Eugenics Education Society, the belief in the predominant value of heredity was tacitly accepted until the feudal system of society approached its final downfall amid the gathering clouds of the industrial revolution. Since then we have all become imbued with the socialist doctrine of fundamental equality and the necessity of providing equality of opportunity, so far as this is possible. Yet this thesis is by no means proven. So far as animal experiments can take us in this difficult problem, they point to the fact that an environmental factor is transmitted and that the offspring of animals living under different environmental conditions do not, therefore, start life with equal capacities. But the question, "Is poverty a mark of unfitness?" remains without an adequate answer, and to provide one Dr. Drysdale suggested an experiment on the grand scale, whereby some hundred children from poor homes should be brought up from birth in circumstances strictly comparable to those of children born in wealthy or aristocratic families, either by arranging for adoption or by providing special institutions. Apart from the cost of such an experiment, the results might well be open to question. Fitness to grapple with the difficulties of adaptation and reality and to make what is known as "a success of life" depend to a large extent on psychological and physiological factors which elude accurate determination. This fact has just baffled an industrial committee specially set up in Massachusetts to select "gifted children in industry" for preferential treatment. Moreover, no two foster-parents would offer precisely the same conditions to the adopted baby, and the expenditure of (say) £500 a year on education would not in itself suffice to make a successful citizen of any child, be he peer or peasant. An experiment along these lines has already been in progress for nearly 14 years at the Caldecott Community, where, at Goff's Oak, near Cheshunt, some 40 children from poor homes are being educated. No attempt is made to ascribe any superior value to intellectual work; the entire work of house, garden, and farmyard is done by staff and children together, three and a half hours per day being devoted to book studies. Nevertheless, those of the children who have passed on to other schools have all taken their places satisfactorily with those of their own age, and in every case special remark has been made on the keenness and freshness with which they work. Miss Potter, one of the honorary directors of the Community, speaking at the same meeting, confessed that the optimism with which the enterprise had been started had not been wholly justified. It could not be claimed that the children of the Community were really indistinguishable from those of wealthy homes; there seemed to be an element which they did not fully acquire, an element, which, for want of a better word, they called "culture," a nicety of perception of values. This, she felt, had only been attained by two children who had been completely adopted. The others return to their homes thrice yearly for holidays, a circumstance which provides an additional difficulty—viz., a double standard of living.

The experience of the Caldecott Community leads to the conclusion that the mentality of children of poor parents follows the same range of variation as that of any other class of child, but the poor child is always a year behind the rich one in mental age This is ascribed largely to lack of sleep; it is found that, when the toddlers first arrive at the school, they sleep for 19 hours out of the 24, while children of 6 and 7 will sleep for 14 hours when they first return from their holidays at home. Accompanying this tiredness is lack of appetite, the food consumption returning to normal about a fortnight after the return. The second factor which seems to account for mental retardation is the lack of intercourse with parents. These children are not played with and talked to as are those of the more leisured classes, and when they first arrive at the Community their outlook is limited to their immediate surroundings. The recovery is rapid; in three months the eyes are no longer glazed, the child is bright and vivacious, and there seems to be an unfolding of the whole personality. The older the child when admitted the longer does this process take, and the Community prefers not to admit children over 7; in those over 12 there is little or no change. In default of large sums for ad hoc experiment, it seems that those interested in such researches might well give their support to such an interesting and deserving enterprise as that of the Caldecott Community. It is the modern equivalent of the "foundations for poor scholars" of which there was such an abundance in the earlier days of higher education.

OPEN-AIR SCHOOLS.

THE first open-air school was established in Vienna in 1903, Charlottenburg followed in 1904, and London in 1907; all over England these schools are being built, and in America there are now between three and four thousand. Mr. I. G. MacInnes has set himself what is obviously a congenial task in making out a case[1] for the open-air school in New Zealand. It might be imagined that a country with such a large rural population would hardly require instruction on this aspect of educational progress, but school buildings in New Zealand are, we are told, "hopelessly out of date," so great have been the changes in class teaching and class methods. The Minister of Education, in a short preface to Mr. MacInnes's pamphlet, states that the whole tendency among educationists nowadays is in the direction of erecting school-rooms of a much lighter and more elastic type than before, and he characterises it as doubtful wisdom to build schools in massive concrete or brick to last a century which are almost impossible of remodelling or modification. The bungalow type of building with separate class-rooms is recommended for New Zealand, but Mr. MacInnes shows how an ordinary class-room may be adapted by cross-ventilation and the use of a suitable type of large window, certainly an improvement on the Plunket system. A separate bungalow for each class, such as may be seen in certain open-air schools in England, has some advantages:—

---

[1] Open-air Schools: A Popular Exposition. Reprinted from the Christchurch Press, New Zealand. Pp. 12. 6*d.*

1. It does away with the distraction of neighbouring classes and noisy corridors.
2. It allows the class-room to be emptied rapidly and quietly.
3. It enables the teacher to let the children out for a brisk run at the end of each half-hour's lesson, in order to stretch tired muscles and straighten bent backs.
4. It gives the architect four walls to work on, and thus ensures a cross-current of constantly renewed air, whatever the direction of wind or rain.

The separate class-room, writes Mr. MacInnes, is, in fact, the key of the whole design. Administration hardly falls within the scope of this excellent little pamphlet, but there are several important details which its readers should take to heart. Children obtaining open-air instruction require extra nourishment; in the majority of these schools the children eat three good meals plus a certain quantity of milk, and they are weighed and measured at regular intervals. A mid-day rest is the rule. No doubt the marvellous improvement in mentality and physique is as much due to the food and rest as to the fresh air, the sunshine, and the educational methods employed. The type of teacher, too, as Mr. MacInnes points out, is most important. "It is essential," he writes, "that teachers in charge of open-air schools should themselves have been trained in their operation and advantages." This does not mean that the services of teachers who have had open-air experience as patients in a sanatorium should be requisitioned. Experience has shown this to be a mistaken policy.

MEDICAL SECRECY AND THE PENAL CODE.

THE new Argentine code does not seem to have solved the very difficult problem of reconciling the conflicting claims of professional secrecy and the criminal law, though, according to Dr. Marcos Victoria,[1] it is an improvement on the old. The violation of professional "secrecy" is, by the Argentine law, a crime per se, as it is in many continental codes, punishable as an offence against individual liberty. Under the new code, not only are the doctors made liable, but all employees of a hospital in whatever capacity, or those in any employment in which their work may entail the possession of medical secrets. Further, it is not necessary that these secrets should be confided verbally and voluntarily by the patient; all information is included which may be acquired by observation or inference in the course of professional duties. The author approves fully of these just and logical extensions. But the new code leaves the position of the doctor very uncertain as regards his duty to reveal secrets in cases of public—i.e., criminal—prosecution; as regards civil suits, the obligation of secrecy remains absolute. Under the former code the doctor was exempt from any obligation to give information. Under the new code the violation of professional secrecy is only punishable when it is done "without just cause." What a just cause is does not seem to be further defined; it is left to the conscience of the individual doctor to decide between the conflict of duties. In the event of his deciding wrongly he is liable to an action for damages by the individual concerned, even in the absence of any proof that he acted maliciously. It seems somewhat doubtful whether he is not also liable to the prescribed penalty for the violation of professional secrecy as his exemption has been removed, but the author relies on the preamble to the code of 1891, which states that violation of professional secrecy being a crime, the keeping of it cannot be one also. It is impossible for anyone unversed in Argentine law and not having the penal codes before him, to judge how far Dr. Victoria is right in relying on the preamble (Span-projecto) of a repealed code, but it seems highly probable that it will not be elucidated until some unfortunate medical man who may have acted in perfect good faith has been victimised in the law courts. There is a good deal to be said for leaving the ultimate decision to the conscience of the individual, provided that when he does act according to his conscience, he is adequately protected, which here seems hardly to be the case. The whole article illustrates the almost insuperable difficulties of trying to reconcile in legislation two points of view which are contradictory and yet can both be maintained by unimpeachable arguments.

POST-GRADUATE ENTENTE BETWEEN AMERICA AND ENGLAND.

IT is now arranged that Dr. Charles Mayo will come to England next summer as President of the annual meeting of the Inter-State Post-Graduate Assembly, instead of Dr. William J. Mayo. Other members of the party will consist of Dr. Franklin H. Martin, of Chicago, Director-General of the American College of Surgeons, Dr. Crile, and Dr. J. B. Deaver, of Philadelphia. Dr. Charles Mayo, in a communication dated Dec. 3rd, has written in the following words: "It certainly will be a big meeting, and I hope it will do a great deal of good not only in creating more harmony between the medical professions of Great Britain and America, but that its influence will be far-reaching on the people who read and hear of it." The meeting is certainly being supported in an auspicious manner and promises to be a large one, and that it will have the useful effect foreseen by Dr. Mayo seems without doubt.

STERILISATION OF TYPHOID CARRIERS BY CHOLECYSTECTOMY.

THE problem of how to sterilise typhoid and paratyphoid carriers has not yet been satisfactorily solved, although the ingenuity devoted to it has found a much varied expression. A remedy which is often effective, but which is also liable to be regarded as unnecessarily heroic, is the removal of the gall-bladder which is often the main, if not sole, reservoir in the body where these bacilli continue to reproduce themselves. In a paper written in French and published in *Acta Medica Scandinavica* (Suppl. VII., 1924) Dr. J. A. Voss, of the Ullevaal Hospital in Christiania, has added to our knowledge of this subject by publishing four new cases in which gall-bladders, infected with typhoid or paratyphoid bacilli, were removed. Cholecystectomy was not performed in these cases with a view to sterilising the patients and rendering them comparatively safe for other people to live with, but because there were signs of cholecystitis threatening the patients' lives. Indeed, in one case there was no knowledge of a previous attack of typhoid fever, and the discovery of typhoid bacilli in the gall-bladder, when it was opened, came as a surprise; typhoid bacilli had not been found in the stools because they had not been sought there. In all four cases several examinations of the stools after cholecystectomy were invariably negative, and the assumption would, therefore, seem to be warrantable that these persons had ceased to be typhoid or paratyphoid carriers. Dr. Voss's comments on these cases suggest that they have somewhat impressed the staff of his hospital, hitherto sceptical as to the value of cholecystectomy for typhoid carriers, with the importance of this measure. He thinks it definitely indicated in one group of cases, and worth serious consideration in another. In the first group there is evidence of cholecystitis—pain or other symptoms. When a person is known to be a typhoid or paratyphoid carrier, and there is the slightest suspicion of these germs causing an inflammatory reaction in their host, an operation is unequivocally indicated. When there are no such symptoms, the decision for or against cholecystectomy in any individual case is a difficult one. Dr. Voss has collected 73 cases from the literature of this subject, and he shows that in about three-quarters an operation rid the stools of typhoid or paratyphoid bacilli. When these cases were classified according to the nature of the operation and of the bacilli in the gall-bladder, it was found that cholecystectomy gave better results than cholecystostomy, and that while four out of every five typhoid carriers were sterilised, only every other carrier of paratyphoid bacilli got rid of them by this means.

TRYPARSAMIDE.

THE Rockefeller Institute for Medical Research in New York announces the release of a drug known as tryparsamide for use in the treatment of human and animal trypanosomiasis and selected cases of syphilis of the central nervous system. The drug will be manufactured by the Powers-Weightman-Rosengarten Co. of Philadelphia, and will become available through the regular trade channels in the New Year. In releasing the drug for the benefit of the public, the Rockefeller Institute desires it to be known that the Institute does not share in any way in profits that may be derived from its sale and that, with the cordial coöperation of the manufacturers, provision has been made for the maintenance of a schedule of prices on as low a basis as possible. Tryparsamide, it may be recalled, was introduced by Heidelberger and Jacobs, and was recommended by them for use in the treatment of neurosyphilis. During the past year no less than five reports have appeared in the *Journal of the American Medical Association*, describing the clinical value of tryparsamide, and the results with a series of 185 cases are given in the *American Journal of the Medical Sciences* for August (1924), by Loevenhart and his colleagues. Of these cases, 84 were subjects showing mental abnormality associated with a positive Wassermann reaction of the blood and spinal fluid, in whom there were pupillary changes, disturbance of reflexes, or muscular incoördination. Out of this number injection of tryparsamide produced mental restoration in 37 and distinct improvement in 38; the blood Wassermann became negative in 49 cases. From among 29 tabetic cases 10 were greatly relieved, and these claimed much improvement in health; 3 were entirely freed from pain and showed much better coördination. Tryparsamide produced amblyopia in 13 cases in this series; in all but one however, this cleared up on cessation of the injections. The drug has also been found satisfactory in the Belgian Congo for the treatment of sleeping sickness, but it is hardly likely that either this disease or the early forms of syphilis will ever be extensively treated with a substance which is relatively toxic.

THE Earl of Balfour and the Right Hon. William Graham have been appointed into the vacancies in the membership of the Medical Research Council caused by the retirement of the Right Hon. Edward Wood and Mr. A. G. Church. Lord Balfour has accepted the Chairmanship of the Council.

IN our advertisement columns particulars will be found of the Malayan Medical Services, giving the vacancies for medical and health officers in the Service with a summary of the conditions governing the appointments (v. Students' Number of THE LANCET published on August 30th last). A memorandum giving some general information regarding mode of life, climate, cost of living, and so forth, can be obtained from Sir E. L. Brockman, K.C.M.G., The Malay States Information Agency, 88, Cannon-street, London, E.C.4.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CI.—TREATMENT OF SORE NIPPLES IN THE LACTATING WOMAN.

MODERN management of the nipples lies rather in forbidding the use of the old methods of "preparation of the nipple for nursing" than in inventing new treatment. Nature prepares them much better than does any artificial device. It is, moreover, necessary to give detailed constructive suggestions rather than to assure the patient and her nurse in general terms that all will be well if the nipples are kept clean, since otherwise tradition may prevail.

It is of great importance to avoid sore nipples, not only because any soreness causes extreme pain to the mother while nursing, but because of the risk of a mastitis and breast abscess supervening on any infection of the raw surface.

Management During Pregnancy.

The practitioner should look at the nipples early in pregnancy, since if they are retracted the sooner appropriate treatment is commenced the better will be the result.

(*a*) *Normal Nipples.*—If the nipples are well formed very little treatment is necessary. The patient must be warned to avoid pressure on the nipple by her clothes, and her corsets must not extend above the waist. After the third month the nipples should be bathed night and morning with warm water to wash away any adherent dead epithelium and lacteal secretion, and should then be dried by gentle friction with a rough towel to render them less sensitive to touch. After drying, a little lanolin may be gently rubbed in. This is probably the most satisfactory method of preparing the nipples for lactation. There is reason to doubt the wisdom of bathing them with methylated spirit or eau-de-Cologne; any attempt to harden them in this way almost certainly predisposes them to crack and they may become rough and sore, whereas ointment keeps the mucous membrane supple. The prevention of cracked nipples is analogous to the prevention of cracked lips, and the use of an emollient in the latter situation is certainly more efficacious than would be any application of alcohol. In the hospital class of patient cases are occasionally seen where a septic crust has formed over the nipple owing to lack of cleanliness and accumulated secretion. Such crusts must be softened with olive oil and removed, and the nipple then treated as described above. The matron of the Mothercraft Training Society at 29, Trebovir-road, S.W. 5, recommends sponging the breasts with cold water during pregnancy and scrubbing the nipples with a soft nail-brush. This treatment is said to harden the nipples naturally and to prevent the discomfort, sometimes amounting to actual pain, often experienced by primigravidæ when nursing is commenced.

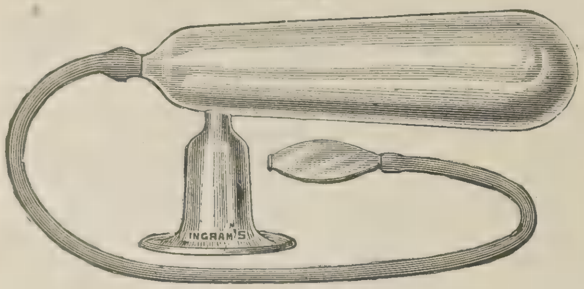
(*b*) *Retracted Nipples.*—If the nipples are retracted the patient must be shown how to encourage them to regain their normal position. This is not such a hopeless proposition as might be imagined, as the nipples are naturally erectile during pregnancy. The best way to encourage a retracted nipple to become erect is by gentle manipulation with the palmar surface of two fingers, one on either side of the nipple. The patient should be shown how to encourage the reflex erection of the nipple, and in most cases the nipple will respond by standing out normally. No force should be used in traction, and both hands and nipples should be clean. This manipulation should be carried out night and morning after bathing the nipples; when the nipple is erect it should be bathed again and lanolin rubbed in, care being paid especially to its apex, which may be fissured and sore. If any attempt is made to draw out the nipple by suction, a self-suction breast reliever (Fig. 1) should be used, never the old-fashioned breast pump (Fig. 2), since any mechanical form of suction exerts undue force upon the nipple. Patience and perseverance are needed in the treatment of retracted nipples—if they are pulled out too hurriedly they will become sore. The old gamps' slogan of "breaking the nipple-strings" both of mother and baby is happily passing into well-deserved oblivion.

Management During Lactation.

The two points to aim at in the postnatal care of the nipples are (1) cleanliness, and (2) avoidance of mechanical injury as far as possible. Before nursing the nipples should be bathed with boric acid solution, and after each feed they must also be bathed to remove all milk, which might decompose on the nipple. They should be carefully dried. If there is any tendency to crack, a little lanolin should be rubbed in round the base of the nipple. The nipple should be protected from the clothing by a pad, about 4 inches square, of sterilised gauze or by a folded large soft handkerchief of silk or old linen; ironing with a hot iron is a sufficient sterilisation for ordinary purposes. Squares of boric lint, although excellent in theory, are in practice rather liable to scratch the nipple. This protective covering must be changed frequently and not allowed to become very damp or hard with dried milk. Overheating the breasts by pads of wool should be avoided.

The following points should receive attention from the nurse in order to prevent sore nipples: 1. The child must not be allowed to drop the nipple frequently and catch hold of it again while feeding; this predisposes to abrasions of the surface from the child's gums. The habit is nearly always due to the baby being held so awkwardly that its nose is pressing against the breast, which prevents it from breathing as it sucks. If it is due to the nipples being retracted the mother should draw out the nipple with a self-suction breast reliever before the child is put to the breast; if the baby is still unable to keep hold of the nipple a nipple shield must be used for feeding. 2. The child should not be put to the breasts too often before the milk comes; three or four times daily is sufficient for the first two days of the puerperium. If there is no milk in the breasts the intense suction exerted by a vigorous child causes a sodden condition of the skin and may even raise a blister on the nipple. 3. Maceration and consequent erosion of the nipple is also caused by too prolonged or too frequent feeding or by allowing the infant to go to sleep with the nipple in its mouth.

FIG. 1.

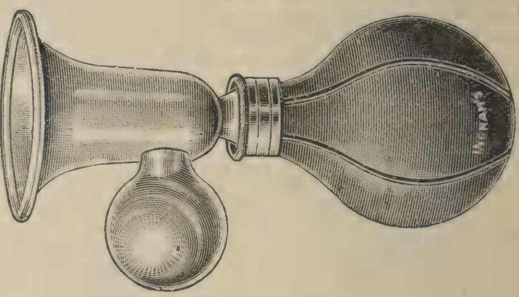


Self-suction breast reliever.

Curative Measures.

When there is a loss of epithelium on the surface of the nipple all septic contact with the eroded surface must be avoided. The nipples must be bathed with boric lotion as usual before and after each feed and must be carefully dried with sterilised or scorched old linen. After drying, an excellent application is the time-honoured friar's balsam (tinct. benzoin. co.). A little should be dabbed on to the nipples and allowed to dry while exposed to the air. The nipples are then protected by the usual pad pinned inside the clothing. If preferred, lanolin or glycerine of borax may be applied in these cases; sometimes glycerine of tannic acid is efficacious. By using alternate breasts for suckling in the ordinary way the nipple is allowed six or eight hours' rest; it is washed as usual for the next feed and the application subsequently renewed. If the erosion is a severe one and the nipple bleeds when the child sucks, a nipple-shield must first be tried, and if the bleeding continues with the shield the breast must not be used for 24 hours; the excess milk may be gently massaged out of the breast to relieve tension and discomfort, by gently but firmly stroking the breast from the periphery towards the nipple, using the flat of the hand and having previously anointed both hand and breast with olive oil.

FIG. 2.



Breast pump.

Another variety of sore nipple shows itself as a crack or fissure usually situated at the base of the nipple, though occasionally seen at the apex. These cracks may be satisfactorily healed in the early stages before infection is present by the treatment described above. If the fissure becomes septic it is much more difficult to cure and is also acutely painful. Antiseptic dressings are indicated and one of the most popular is gauze soaked in perchloride of mercury 1 in 1000. This dressing must be kept damp and not allowed to dry on the nipple. Its poisonous character is a disadvantage, and it must be very carefully and completely washed off before the baby feeds. The same applies to carbolic lotion 1 in 80, which has the advantage of its slight anæsthetic property. Collosol iodine is a satisfactory antiseptic for sore nipples, being effective and non-irritating. Sometimes one or at most two hot fomentations on the nipple will improve a septic fissure, after which tinct. benzoin. co. may be painted into and over the crack and left to dry. The nipple should never be fomented for any length of time as the epithelium becomes sodden and macerated very easily. If fomentations are necessary for the breast on account of coincident mastitis, a hole must be cut for the nipple both in the lint and in the oiled silk and wool covering it. If the fissure is a deep one, applications of silver nitrate are useful in promoting healing. The disadvantage of touching a fissure with the solid silver stick is the pain caused by the method, but it may be worth while in the case of a very deep and painful fissure, cocaine having been applied previously. 1 or 2 per cent. solutions of silver nitrate are not very painful and so in most cases are preferable; the silver solution must be applied with great care to the actual fissure, avoiding all contact with the surrounding skin. In all bad cracks of the nipple it is better to rest the nipple for 24 hours. Even feeding through a nipple-shield or the mother drawing off the milk herself through a self-suction breast reliever tends to open up the crack again.

VIOLET I. RUSSELL, M.D. Lond.,
Assistant Obstetrician, Elizabeth Garrett-Anderson Hospital.

Public Health Services.

MENTAL HOSPITALS SERVICE.

AT the *West Riding Mental Hospital, Wakefield,* an investigation begun some years ago into the mode of spread of dysentery and enteric fever has now been brought to a close, and the hospital is now entirely free from these diseases; hundreds of cases occurred during the war years, when bacteriological work was at a standstill, and the numbers have diminished rapidly since, until, in 1923, no cases were recorded. From the professional reader's point of view it is unfortunate that a brief account is not given of the nature of this work, and of the "trustworthy bacteriological means" found for controlling the incidence of these diseases. We are aware from Prof. Shaw Bolton's observations in previous reports that agglutination tests are performed on every new admission; "Widals, ordinary" numbered 531 during the year under review, but on the information available we are at a loss to explain "Widals, spacial (animal)," which numbered no less than 1639. Does this, perhaps, refer to an outbreak of fowl typhoid which is noted as having been diagnosed by the pathological department? In any case the staff are very much to be congratulated on the complete success of their efforts at ridding Wakefield of these diseases. In two other respects the year's work must have been disappointing; new cases at the out-patient department numbered only 37, a slight decrease, and in the nurses' examinations three female nurses only obtained the M.P.A. certificate, and seven men and two women passed the preliminary examination, these being extremely meagre figures for an institution employing over 400 nurses and attendants, where full courses of instruction are given. In future a hospital-trained deputy chief nurse is to undertake the practical nursing training of the staff. Owing to several changes among the medical staff (which now includes six assistant medical officers), the hospital no longer boasts the remarkable distinction of a staff all possessing the D.P.M. Several minor criticisms are made by the visiting Commissioner; he suggests more varied breakfasts, the more liberal supply of overcoats, and the provision of means for heating water and food at night in some of the male dormitories. No less than 31 per cent. of the deaths having been attributable to senile decay, it is suggested that some of the senile dements, in whom any acute mental symptoms that there may have been have passed away, should be accommodated in the workhouses of their districts.

The *Surrey County Mental Hospitals* are Brookwood and Netherne, accommodating 1393 and 980 patients respectively, and each possessing three permanent medical officers and one temporary. At the former hospital there is now a small amount of surplus accommodation, whereas Netherne is overcrowded on the male side to the extent of 16 patients. Both hospitals now possess a visiting physician, surgeon, ophthalmic surgeon, and dental surgeon. There appears to be serious need for new and better classified accommodation, as by the provision of an admission hospital and convalescent villas. It is noted, however, that tuberculosis is adequately segregated at Brookwood, new verandahs for female cases of tuberculosis having been erected last year. The Commissioners visiting this hospital suggest also the provision, when possible, of an operating theatre and a laboratory, the arrangement of one or more open-door wards, and the provision of supper and arrangements for sitting up in the evening for some of the better-behaved patients; at present, apparently, all patients retire at or before 7.30. Criticism at Netherne is directed to the absence of a laboratory, of charts and bed tables in the infirmary wards, of open fires in the day wards, and the comparative lack of books, pianos, and billiard tables; service patients complained of the absence from their wards of the two latter amenities. Regular cinema entertainments are given. It is noted with surprise that both these hospitals are without a charge night officer. Pressure is being brought to bear on the nursing staff to take their qualifying examinations. There is a curious anachronism in the title of this report, which reads in full "The Annual Report of the Lunatic Asylums Visiting Committee in relation to the County Mental Hospitals at Brookwood and Netherne." The relative merits of the expressions "asylum" and "mental hospital" are debatable, and here the strictest impartiality is observed by employing both, but it is generally agreed that the word "lunatic" should be discarded. Used officially it is an unlucky survival of mediævalism.

That the remote situation of the *Inverness District Asylum* does not militate against its efficiency is, perhaps, best evidenced by the fact that all nurses and attendants are expected to enter for the M.P.A. certificate; six candidates were successful in the final and ten in the preliminary examinations this year. There are at present 661 patients in the asylum, and three medical officers. The incidence of tuberculosis appears unduly high, 21 deaths being attributed to this disease last year, but it appears that known cases are efficiently isolated; it does not appear, however, whether the dietary is such as to defend the patients at once against infection by this disease and against the severities of the climate. It is noticeable that adverse criticisms of dietaries, clothing, and kindred provisions are very rarely made by Scottish visiting Commissioners, whereas in the reports of English mental hospitals they are exceedingly common. Whether this contrast may rightly be taken to indicate such a radical difference between the standards of living of English and Scottish asylums, as it immediately suggests, it would be exceedingly interesting to know. Much employment continues to be afforded to patients by the construction of a new reservoir. New arrangements have been made for dealing with outbreaks of fire. The medical superintendent, Dr. T. C. Mackenzie, impressed by the success of the out-patient mental clinic at Dorchester (which serves a somewhat analogous rural district), urges the establishment of a similar clinic in Inverness.

At the *Derby Mental Hospital* there are 400 patients, and surplus accommodation for 67, with two medical officers. The recovery-rate for the year was 32·5 per cent., and the death-rate 8·6 per cent. No enteric or dysentery has occurred; eight cases of tuberculosis are under observation, and an epidemic of influenza affected 80 patients, causing three deaths. The certificate of the M.P.A. is held by 60 per cent. of the male nursing staff, and by 30 per cent. of the female. A "parole ward" on the male side has been instituted, and certain other changes now afford the patients more freedom and recreation than formerly.

Our amazingly incomplete and haphazard provisions for dealing with mental deficiency are recalled by the report of the *Lancashire and Cheshire Society for the Permanent Care of the Feeble-Minded,* which controls one of the few institutions in this country adequately equipped for the training of the mentally defective. Nine-tenths of the income maintaining this work consists of grants from local authorites; the remainder, and the capital for extensions, is provided by voluntary subscriptions, and this report is, incidentally, an appeal for funds. The present accommodation is for 296 inmates; a new house for 25 patients is nearing completion, and the number of applications is greatly in excess of this number. The existing inmates hail from no less than 77 different localities, scattered over the country as far apart as Scarborough and Dorest, Anglesey, and Ipswich. A recreation room is also being built. Complaint is made of the action of certain local authorities in withdrawing maintenance grants at the age of 16, when training is incomplete, and discharge can only result in the child's becoming a cost and a danger to the community.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the health statistics for eight county boroughs for the year 1923 :—

Name of county borough.	Estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Sunderland ..	164,000	24·6	13·8	1·4	1·1	3·0	28	98	4·0
Birkenhead ..	151,400	21·4	11·0	1·0	1·2	2·4	33	63	4·0
Middlesbrough	135,400	27·5	13·0	1·4	1·1	3·0	37	86	3·2
Derby	132,800	19·7	11·6	1·1	1·3	2·2	32	64	2·7
Preston	121,700	19·1	13·8	1·1	1·3	3·4	41	98	4·9
Wigan	91,640	22·4	13·4	0·9	0·7	4·0	47	101	2·4
Bury	57,250	15·0	16·0	1·0	1·5	4·8	48	102	2·3
Great Yarmouth	57,240	18·8	12·9	1·4	1·5	1·7	27	59	2·8

Sunderland.

Dr. Henry Renney reports that of 99 samples of milk examined for tubercle bacilli 11 gave a positive result. As the result of following up the samples to the farms from which they came, several cows with tuberculous udders were discovered by the veterinary surgeon. In every such instance a written undertaking was obtained from the farmer not to send the milk from the affected cow into the borough. Apparently no effort was made to persuade the farmer to have the affected cow slaughtered, and the procedure adopted in Sunderland appears to be an argument for the reintroduction of the Tuberculosis Order of 1914. The maternity and child welfare medical officer, Dr. Eustace Thorp, is greatly impressed with the good results obtained by the admission of children suffering from bronchitis, indigestion, marasmus, and rickets into the wards of the borough sanatorium for infectious diseases. A month or so with regular and good feeding, combined with sufficient rest, often works wonders for such children. Dr. Thorp regrets that there is no ear department in the town capable of dealing with the numerous cases of discharging ears. He also mentions that examples of intensive dental decay are found at all the centres in children from 2 to 4 years old, for which there is as yet no provision. Antenatal work is growing slowly. The midwives in Sunderland attended, during 1923, 76 per cent. of the births.

Dr. N. F. Rowstron reports that an antenatal session for pregnant women suffering from V.D. has been started. Of the 13 syphilitic expectant mothers treated 12 gave birth to healthy children with a negative Wassermann reaction, and one to a child with a weak positive reaction. Of the 12 children born to syphilitic mothers treated in 1922, 11 have remained well, and one who had a weak positive reaction at the sixth month received treatment. The sanitary inspector's report shows that it is impossible to deal with overcrowding owing to the lack of housing accommodation. Only 20 new houses were erected during the year, none of which were municipal houses. The conversion of the privies into water-closets has now been almost completed.

Birkenhead.

Dr. D. Morley Mathieson says that an important step was taken in October, 1923, when the council decided to proceed with the erection of a large number of houses on available sites in the borough, in order to relieve overcrowding and to facilitate the closing and demolition of unfit dwellings. The mistake of rebuilding in thickly populated districts must be avoided, says Dr. Mathieson, for the provision of a healthy situated home for his wife and children ought to mean, and in by far the majority of cases does mean, more to a worker than the convenience of living next door to the shipyard or factory. He discusses the housing question in the Census figures, dealing with it at some length. The total number of private families in Birkenhead at the 1921 Census was 31,475, and the number of "structurally separate dwellings" was 26,630. Of the separate dwellings 3035 were occupied on Census night by two families and 753 by three or more families. A considerably higher percentage of families occupied dwellings of one, two, and three rooms in 1921 than in 1911. Dr. Mathieson thinks the borough is cramped for space, as compared with other towns. The population density was 37·2 per acre in 1921, as compared with 33·9 in 1911, and with an average density of 19·6 for the county boroughs in 1921. If overcrowding is judged by the standard of the excess of two persons in a room, Birkenhead with a percentage of 12·6 does not differ much from the other Mersey-side industrial boroughs—e.g., Liverpool with 12·1, Bootle with 11·1, and Warrington with 12·1; whereas the group of five Tyne-side and Wear-side boroughs have an overcrowding percentage exceeding 30. It is questionable whether this standard for overcrowding gives a means of fair comparison between one borough and another. Dr. Mathieson's table shows that the percentage overcrowding figure for the 82 county boroughs of England and Wales is 10·8. Great Yarmouth heads the list with a percentage of only 2·1, and the percentages for the other towns in the above table are Derby, 3·5; Bury, 4·7; Preston, 7·4; Wigan, 15·3; Middlesbrough, 16·0; and Sunderland, 38·8. Dr. Mathieson shows that the population of Birkenhead has grown rapidly in recent years, and increased by 20,606 between 1911 and 1923, and that there has been no increase in housing accommodation adequate to meet this increase. At the end of the year it was decided to appoint two more inspectors in order to fulfil the council's obligations under the Housing Acts.

The joint sanatorium for tuberculosis at Burntwood for Cheshire county, Wallasey, Chester, Stockport, Stoke-on-Trent, and Birkenhead was opened in November, 1923, as regards 50 per cent. of its accommodation. Birkenhead's share is 32 beds, of which 16 are now available. A trial has been given to Dreyer's defatted vaccine, and Paget's nasal insufflations at the Thingwall Sanatorium, but the results were not encouraging; 12 beds are reserved for the treatment of surgical tuberculosis at Leasowe Hospital. At the end of the year an agreement was being negotiated with the Birkenhead Borough Hospital for the provision of beds for complicated cases of confinement, for complications arising after parturition, for pregnant women suffering from illness or deformity, and for cases of women who cannot with safety be confined in their own homes.

In his school report Dr. Mathieson presses for an open-air school :—

> "From among the children at present attending elementary schools in Birkenhead," he says, "there would be no difficulty in selecting several hundreds, who are physically unfit to benefit by the instruction provided for them in ordinary school premises, but who are forced, nevertheless, to attend school year after year. . . . Valuable time and energy of teachers is being thrown away, and the health, educational future, and wage-earning potentiality of the children concerned jeopardised."

The dental scheme was curtailed in 1922, and Dr. Mathieson makes out a strong case for reopening the consideration of the matter, with a view to adopting the original scheme. Another need of the Birkenhead schools is a coördinated and complete scheme for dealing with crippled children.

Middlesbrough.

Dr. Charles V. Dingle reports that from the sanitary point of view the most important event of last year was the completion of the water-carriage scheme, nearly 9000 conversions having been carried out during the year 1923. Great attention has recently been given to the milk-supply of the town. Experimental work has been done at the corporation farm at Hemlington. The first sample of milk examined from Hemlington gave 367,500 bacteria per c.cm., and *B. coli* in 1/10th and in 1/100th of a c.cm. Instructions were given that the milkers should wash their hands and wear clean overalls and caps, that the cows' udders and hind quarters were to be groomed, and Sirrell's patent pails used. The next sample, after these instructions, gave 17,200 bacteria per c.cm., and *B. coli* in 1/10th of a c.cm., but not in 1/100th. It was found that a considerable amount of dust from the cows' flanks was deposited during milking on the top of the patent pails, so that when the pail was tilted in emptying it into the cooler this dust fell into the cooler. The pail tops were therefore wiped with a damp cloth before tilting, with result that *B. coli* has now been eliminated. The corporation, having put its own farm in order, now recommends farmers whose samples are unsatisfactory to go and do likewise, with very satisfactory and encouraging results. Attention is also being given to the retailers. The premises of many retailers were ordinary dwelling-houses with sheds in small backyards for the business. There were also a number who sold other goods such as "patent fire-lighters, paraffin oil, vinegar, yeast, potatoes and vegetables, meats, dried fish, &c." During 1923 a regulation was passed prohibiting the sale of milk, except bottled milk, in all such general shops. The supply of milk and demand for milk in properly sealed bottles is growing, and up-to-date dairy shops, previously unknown, selling milk, butter, and eggs only are beginning to make their appearance.

Dr. Dingle points out that the decrease of infant mortality has been concomitant with the decrease in the prosperity of the town since 1920. Thus, the rates for the last four years have been 135, 118, 111, and 86 respectively. He points out that decreased prosperity has resulted in decreased pollution of the atmosphere, increased breast-feeding, increased use of dried milk in the place of dairy milk, and an increase in the number of mothers who take advantage of the various activities of the maternity and child welfare department. Alluding to the theory that the decrease in the consumption of alcohol has been a factor throughout the country in bringing about the decline in infant mortality, he states that this has not been an operating factor in Middlesbrough. For the four years 1916–19 the average annual prosecutions for drunkenness were 553, while for the four years 1920–23 the average prosecutions were 1300. Every effort is made to encourage breast-feeding, and 86 per cent. of the dried milk, given under the Milk Order, is given to expectant and nursing mothers. Dr. Dingle thinks that the slight increase in the death-rate from tuberculosis during 1923 may be due to unemployment, poverty, and insufficient feeding, and also to the want of progress in housing. The corporation retain six beds at the Broomlands Home for the surgical treatment of tuberculous children. No Exchequer grant is payable towards the cost of these beds as Broomlands belongs to the Poor-law authority.

The Dacre-street area improvement scheme is being proceeded with. The original proposition was to demolish 62 houses and build 18 new houses on the same site. The Ministry of Health has decided that the site should not be rebuilt upon, and 57 houses will be erected on the Acklam-road garden colony to accommodate the 285 persons dishoused.

Derby.

Dr. A. E. Brindley says that neither cubic capacity nor the number of persons exceeding two to a room gives a true picture of the pernicious results of overcrowding. He gives in his report examples of the disastrous effect in the case of infectious disease, and the urgent need for separate bedroom accommodation for opposite sexes. He also includes in his report extracts from the letters of applicants for new corporation houses to illustrate the conditions under which many families are living. At the same time, he says, there are signs that the efforts of the housing committee are beginning to give beneficial results. Since August, 1919, 799 new corporation houses have been completed. There are now 79 in course of erection, and 160 are about to be begun. During the year 26 samples of milk were examined for tubercle, and four were found to be infected, giving the high percentage of nearly 16. In one of these cases difficulty was found in persuading the farmer to have the three cows found with tuberculous udders on his farm slaughtered, until pressure was brought to bear by the health committee. It is stated that approximately 60 per cent. of the population of the town obtain their milk from the Coöperative Provident Society, and that this supply is pasteurised. Dr. Brindley does not mention whether this society has adopted plant in accordance with the new regulations. The scarlet fever pavilion of the isolation hospital has been greatly improved by the provision of a large verandah, "as it is found that the open-air method of treatment gives far and away the most satisfactory results." Referring to the question of atmospheric pollution, Dr. Brindley says that although Derby is not considered a smoky town everyone will admit that there is room for considerable improvement.

Preston.

Dr. F. A. Sharpe states that during 1923 insulin was made available to doctors for administration to insured persons. The original cost was about 35*s.* for a week's supply, but this has been gradually reduced to about 15*s.* The total drug bill under the Insurance Act was £7933, an increase of nearly £1500 on 1922. Dr. Sharpe thinks the increase may be due to the conspicuous absence of sunshine in 1923, and the low vitality consequent on unemployment. The amount of unemployment benefit paid during the last quarter of the year averaged £3850 per week. Dr. Sharpe draws attention to the excessively high permissive limit adopted for black smoke from factory chimneys. This limit is five minutes' black smoke in a half hour observation, which is five times the limit found practicable in Sheffield. Dr. Sharpe goes on to draw attention to the high death-rate from bronchitis and pneumonia on the Western Lancashire seaboard, which he associates with the excessive industrial smoke. Out of 51 samples of milk examined bacteriologically nine were found to contain tubercle bacilli, a percentage of 18. Dr. Sharpe advocates taking samples from every source of supply at least once a year, and in the case of the larger herds every six months, and the adoption of a uniform system of veterinary inspection throughout the country. A food poisoning outbreak occurred in September, which was found to be associated with potted meat infected by an organism closely resembling the *Bacillus dysenteriæ* (Flexner). A very careful investigation as to how the meat became infected gave a negative result.

Wigan.

Dr. Henry Whitehead again points out how much is needed to make the sanitary conditions of Wigan up to date. The big scheme for the conversion of privies and pail closets has, however, now been put in hand. Great progress has also been made in dealing with insanitary property and in the paving of backyards. The provision of suitable refuse receptacles for all houses, and the adoption of covered carts in lieu of the present open refuse carts are mentioned among the things needed. Crude refuse from ash-tubs, bins, and privies is still tipped without the precautions suggested by the Ministry of Health. Sites for a public abattoir have been inspected but no decision arrived at. The gathering grounds of the water-supply were found to be liable to pollution as the result of an inspection by the health department made in 1922. These supplies are being chlorinated, whilst other suggestions for permanent improvement are under consideration. Dr. Whitehead points out that the infant mortality of Wigan for 1923 was the second highest of the 105 large towns. A maternity home is necessary in Wigan, he says, as confinements often take place under wretched conditions; and more health visitors are essential.

Bury.

Dr. G. Granville Buckley, in commenting on the high general death-rate and the high rate of infant mortality, refers to the nuisance caused by the existence of a large number of privy middens. The conveniences in the borough are as follows. 8223 ordinary water closets, 3184 waste-water closets, 560 pail closets, and 4230 privy middens. "At the present rate of progress," says Dr. Buckley, "nearly 30 years will have elapsed before the whole of the sanitary conveniences have been converted to the water-carriage system." Smoke observations of mill chimneys to the number of 263, each of 30 minutes' duration, were made during the year. The permissible limit for black smoke adopted by the council is two minutes in the half hour, or twice the limit allowed in Sheffield. Particulars are given of five observations in which the limit was exceeded. The average for these five chimneys was 6½ minutes of black smoke and 15½ of "moderate" smoke, and eight minutes of no smoke in the half hour. It is well recognised that there is no such thing as smoke black as a silk hat, and the crucial point in these observations is, what is "moderate" smoke? On the face of it a chimney which only fails to give off smoke for eight minutes in the half hour is doing its "bit" to pollute the atmosphere. The school report shows that there is no open-air school, no dental clinic, and no special provision for dealing with crippling defects.

Great Yarmouth.

Dr. A. N. Stevens mentions that all the dwelling houses in the borough, with the exception of 24, are supplied with company's water, which is obtained from the Ormesby Broad and the River Bure, and pumped into the mains after filtration. The existing 24 wells are, says Dr. Stevens, "without doubt liable to pollution at times, but unless the samples for analysis happen to be taken at one of those times they cannot be dealt with." About 20 per cent. of the mothers of illegitimate children went out to work, and 51 per cent. of these children were artificially fed. No tube bottles were found to be in use. "Bread or biscuit pap was given from an early age in one case only, though this practice appears to have been almost universal amongst the poorer classes of Great Yarmouth a few years ago." Dr. Stevens explains that the duty of the rat officer is not to act as rat-catcher, but to compel the occupiers of premises to take the necessary steps to destroy rats or mice. The corporation have, however, recently appointed an official rat-catcher. For many years it has been the custom for the corporation to pay 1*d*. for every dead rat brought to the health office. During 1923 2712 dead rats were so brought. The hours of bright sunshine recorded were 1653.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 6TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 62; scarlet fever, 2076; diphtheria, 1152; enteric fever, 62; pneumonia, 1150; puerperal fever, 48; cerebro-spinal fever, 7; acute poliomyelitis, 7; encephalitis lethargica, 46; dysentery, 21; ophthalmia neonatorum, 106. There were no cases of cholera, plague, or typhus fever notified during the week.

Dr. R. W. C. Pierce, medical officer of health for Woking, informs us that the 20 cases of dysentery (12 this week, 8 last week) reported by him were notified from the Brookwood Mental Hospital.

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, none from small-pox, 13 from scarlet fever, 37 from diphtheria, 50 from measles, 85 from influenza. In London itself the deaths from diphtheria numbered 17, from infantile diarrhœa 13.

Special Articles.

ST. THOMAS'S HOSPITAL APPEAL:

BANQUET AT THE LONDON MANSION HOUSE.

AT the invitation of the Lord Mayor of London a banquet in aid of the funds of St. Thomas's Hospital was held in the Egyptian Hall of the Mansion House on Dec. 10th, when covers were laid for over 350 guests. The Lord Mayor, who was accompanied by the Lady Mayoress, presided, and in spite of the thick fog with which London was enveloped at the time, there was a brilliant gathering of the supporters of the hospital. An appeal for £60,000 is being made to pay off a debt on the hospital.

The Lord Mayor proposed the loyal toasts, which were received with musical honours, and Lord Darling proposed "Success to the Voluntary Hospital System" in his usual felicitous terms. He believed, he said, in the voluntary system because he was old-fashioned enough to object to everlasting interference by the State. There were those who held that everyone should be brought up by the State, which would probably mean that their fathers would not be allowed to choose their names, and that the great historic families would be known by the letters "A" and "B," and so on. In circumstances of State control, if a man were knocked down on a foggy night by State taxicabs or omnibuses he would be picked up by "uniformed pickers" and treated at the communal hospital and operated upon for whatever malady had been set down for that day. The country, he continued, was best governed by as little State interference as possible. The voluntary system as applied to hospitals had proved a decided success, as shown by the vast sums received from voluntary effort.

Sir Charles Wakefield, who responded, said that there must have been many moments during the last five or six years when the state of the finances of more than one of our great hospitals had been desperate in the extreme, and when there seemed nothing for it but to give up the struggle and seek help from the State. Though the situation was still precarious, it was more promising and more healthy because the hospital authorities had found new sources that were saving the situation. These had not yet been fully developed, but they had saved the voluntary principle. Voluntarism was the very life-blood of charity. "Hand the hospitals over to the control of the State," he said, "and the freedom that secured such beneficent results in treatment and research would be banished for ever. Whatever its virtues in other spheres, in this the State would indeed be the skeleton at the feast. Its icy breath might sterilise, but it would not stimulate."

The toast of "St. Thomas's Hospital" was proposed by the Lord Chancellor, Viscount Cave, who said that when he presided over the Committee which was appointed to find out what was wrong with our hospitals, he came to that inquiry with an entirely open mind, but as those who held the inquisition saw pass before them the procession of presidents, treasurers, governors, officers of the hospitals, and the great physicians and surgeons of the day, the conviction grew upon them that to our English hospital system, which only the English-speaking nations knew, there was owing a greater debt than could ever be paid. He referred to the valuable work which the hospitals did during the war, and pointed out that these institutions were not only training grounds for doctors and nurses, but were centres of research on which we must depend and base our hope of the future.

In his reply, Sir Arthur Stanley, treasurer of the hospital, emphasised the need for a wider appreciation on the part of the public of the work done, and was being done, by St. Thomas's Hospital, and for a realisation of the fact that, contrary to the general opinion, the hospital was not enormously rich. The income derived from its endowments fell far short of the money that had to be spent upon the innumerable branches of its work. He pleaded for a larger number of yearly subscriptions, pointing out that if the hospital could only get two or three thousand of £1 a year each, that would be worth to it as much as a capital sum of £50,000. In conclusion, he said that the donations received from patients were really wonderful. Four or five years ago they amounted to £1400; they had now reached an annual total of £14,000. Sir Arthur Stanley read a telegram from the Duke of Connaught, the President of the hospital, as follows:—

> "I regret that my absence abroad makes it impossible for me to attend the dinner at the Mansion House in support of the appeal on behalf of St. Thomas's Hospital. In the course of my long connexion with the hospital as its president, I have learned fully to appreciate its beneficent work in ministering to the suffering poor, and I am sure that all who are acquainted with the vast extent of its humane activities in the crowded localities of South London will desire the continuance of its work, and will feel it to be their duty, as it is their privilege, to remove the financial difficulties with which its mission of healing is beset. I can never forget that during the war the hospital undertook very heavy work as the Fifth London General Hospital, when it treated 530 military cases every day, in addition to its ordinary civil work."

During the evening, Mr. G. Q. Roberts, the secretary of the hospital, read a list of subscriptions which totalled £42,276. These included £5000 each from Mr. Samuel Samuel, M.P., Mr. Frederick Lane, Lord Bearsted, the William Shepherd Trustees, and the Treasurer and three almoners, £2500 from Lord Riddell, £2000 from Lord Glendyne, £1000 from the Mercers' Company, and £100 from the Lord Mayor.

IRELAND.

(From our own Correspondent.)

The Irish Free State and the Medical Register.

The question of the relation of the Irish Free State to the Medical Register having been raised in the Dail last week, Mr. McGilligan, Minister of Industry and Commerce, made a full statement on the matter. He explained that he had attended a conference on the subject some time ago and it was deemed advisable that certain legislation should be introduced in Dublin and London to validate what had been done previously and continue the operations of the General Medical Council for a period to be defined in the Acts. He had introduced a Bill as a matter of urgency, and while engaged in the Senate he was informed that there was still a certain point in dispute. The Bill had been postponed, and the change of Government in Great Britain had delayed the further consideration of the question. There was no indication on either side of any desire to alter the existing state of affairs. He hoped to have the question settled shortly. Prof. W. E. Thrift thanked the Minister and asked him to do all in his power to hasten matters in order to arrive at a satisfactory termination. The Minister promised that he would lose no time in the matter.

Prize-giving at the Royal College of Surgeons.

Mr. R. C. B. Maunsell, President of the Royal College of Surgeons in Ireland, addressing the students of the College school at the annual distribution of prizes last Saturday, advised the students to make sure of holding the appointment of resident pupil at their hospitals. The resident pupil system was distinctively Irish, and was a most valuable part of education. It taught a student how to examine a sick person, and gave him confidence and "nerve." After qualification he advised them to seek resident appointments as physician or surgeon, if not at home, then in Great Britain. He commented favourably on the method of selecting medical officers for the public service by an expert selection board, a trial of which had recently been made at the instance of the Ministry of Local Government.

Doctorate in Literature for Dr. Kirkpatrick.

At the Winter Commencements of Dublin University the degree of Doctor in Litteris was conferred on Dr. T. P. C. Kirkpatrick, Fellow and Registrar of the Royal College of Physicians of Ireland. Dr. Kirkpatrick is the first medical graduate of Dublin to attain this very select degree. He is the author of several historical studies, dealing with the history of medicine in Ireland.

A Memoir

of

Prof. JOHN IRVINE HUNTER, M.D. Sydney.

By Prof. G. Elliot Smith.

It is impossible to convey to those who have not come under the spell of his personality any adequate conception of the magnitude of the loss anatomy and, in fact, medical science in its widest sense, have sustained in the death of John Hunter. The great name he bore would have overwhelmed a smaller man; but it is no exaggeration to claim that he has added fresh lustre to it. In the brief four years of his professional life this youth was the professor in charge of a department of anatomy, in which great reforms in teaching and research were being achieved. Of this time he spent 18 months travelling in Europe and America widening his knowledge of medical education. His elucidation of the difficult problems of ovarian pregnancy, of the true reconstruction of the Piltdown skull and its significance, of the factors that determine the nature of spinal shock, the comparative anatomy of the oculo-motor nucleus, and especially the functional significance of the sympathetic innervation of striated muscle and the central control of muscular tone were each of them tasks of the first magnitude the successful accomplishment of which would have brought fame to the man who had devoted his life-time to any of them. Yet Hunter did all these things along with his other work before reaching the age of 27 years. The secret of his greatness lay not merely in his knowledge, though it was almost uncanny in its range and precision; nor even in the wide vision and keen insight, which enabled him to find his way through the mazes of the most intricate problems, and appreciate the deeper significance of the information he acquired by observation and ingenious experiment. It was rather the greatness of his personality, his transparent honesty and thoroughness, that compelled respect for his judgment and conferred upon him powers which would certainly have made him one of the really great figures in the history of scientific achievement. Such qualities of mind are extremely rare, and especially in combination with an unselfishness and magnanimity, a charm and joyous understanding that awakened the deepest affection in all who came into intimate association with him.

Early Life.

John Irvine Hunter was born in January, 1898, at Bendigo, in the State of Victoria. So far as can be discovered there was nothing whatever in his ancestry to throw any light upon the source of his genius. Apart from the devotion of his mother his circumstances were singularly unfavourable for the development of his remarkable aptitudes of mind and personality. But in some inscrutable way he seemed to turn to good the grave misfortunes that afflicted him in his early childhood. His intimate experience of surgeons during infancy inspired the child of 7 years with the desire to enter the profession of medicine, which had rescued him from the life of a cripple. A serious attack of pneumonia soon afterwards induced his mother to send the convalescent child to his aunt at Albury in New South Wales, in which State the rest of his life was spent. This move to the Mother State of Australia was a very fortunate chance, not merely because the bursary system opened the way for him through the State Schools to the University, but also because it brought him under the influence of Prof. J. T. Wilson, F.R.S., now of Cambridge, who played a dominant part in shaping his scientific career—as well as his social ideals. During the period of his studentship at the university he had to forego sports, in which he was keenly interested, and spend all that under happier circumstances would have been his leisure time in coaching for a living and to help his mother, who had made great sacrifices to obtain surgical attention for him in his infancy. But instead of becoming depressed by his early struggles he seemed to get an added zest for the joy of life from the feeling that he had surmounted his difficulties. He was a most delightful and joyful companion, and it was amazing that, in spite of the adulation showered upon him by students and the public, he always remained the most modest and unassuming of men.

Academic Honours.

During the last two years of his course he served as a demonstrator of anatomy and displayed a very keen interest in neurology, especially in the sympathetic system, which was destined to be the field of his greatest achievement. While yet an undergraduate he wrote an essay (awarded the Sandes Prize in Surgery) which he called "An Interpretation of Abdominal Pain," using clinical evidence collected by himself as the material for a penetrating and original analysis. When he graduated (with first-class honours and the University medal) in March, 1920, he was at once appointed senior demonstrator of anatomy. But Prof. Wilson, realising that—though there were urgent reasons why Hunter should immediately assume the responsibility for teaching anatomy, some experience of clinical medicine and surgery was of vital importance to an anatomist—arranged with the hospital authorities to let Hunter act as a resident in the Royal Prince Alfred Hospital during vacations.

A couple of months after Hunter's graduation Prof. Wilson was appointed to the Chair of Anatomy in Cambridge and in July, 1920, Hunter became Associate Professor of Anatomy at the age of 23 years. Before Prof. Wilson left Australia at the end of the year he persuaded the University of Sydney to put the youthful professor in charge of the department of anatomy, and to agree to give him the opportunity to widen his experience by visiting medical schools in Europe and America. Hence in August, 1920, he set out for England and he returned via America to Australia in February, 1922.

But before he left Australia the burden of his heavy responsibility seems to have sat lightly on his shoulders, for in addition to the task of teaching and learning to administer a great department, he accomplished three important researches in utterly different fields of embryology, anthropology, and physiology. He cleared up many of the difficulties in the interpretation of ovarian pregnancy, in the real significance of the occurrence of Neanderthaloid characters in aboriginal Australians and in analysing the complicated factors of spinal shock following transverse section of the spinal cord.

His Published Work.

The first of these three noteworthy memoirs was published in the *Journal of Anatomy* in January, 1922. The special value of the case of primary ovarian pregnancy was due to the early period of development and the clearness of the evidence in demonstration of the fact that the ovum was fertilised as the closing coagulum was formed in the mouth of the Graafian follicle and proceeded to develop in the connective tissue in this situation, embedding itself *ab initio* outside the growing corpus luteum of pregnancy. The lucidity of the account of this specimen and the interpretation of its complexities afforded the first indication to the anatomical world at large that a new John Hunter had arisen.

The results of the experimental work that he carried out in collaboration with Mr. N. D. Royle between October, 1920, and July, 1921, were not published until this year ("The Symptomatology of Complete Transverse Lesions of the Spinal Cord," *Australian Journal of Experimental Biology and Medical Science*, 1924, i., 57). By means of an ingeniously devised series of experiments he courageously attacked a difficult problem which had taxed the skill of many of the best experimental physiologists and clinical observer of Europe and America. In particular he addressed himself to the task of deciding whether or not vascular disturbances played a part in determining spinal shock. He showed that the variations in the ultimate results after section of the cord cannot be wholly explained by release of function alone. These may be combined with release of function (due to section of the conducting pathways), vascular changes leading to rapid degeneration. or a temporary stage of hyperexcitability of the nerve-cells. The experience gained in this preliminary investigation was destined to prove of far-reaching importance when in 1922 Hunter and Royle embarked upon the still more difficult task of cutting the Gordian knot of controversy regarding the sympathetic innervation of striated muscle and the central control of muscular tone.

Study Abroad.

But before undertaking this work Hunter spent 18 months in Great Britain, Europe, America, and New Zealand, getting into touch with the medical schools of the world. He went first to his former master, Prof. Wilson, in Cambridge, who magnanimously allowed us at University College, London, to have the privilege of Hunter's stimulating help for a whole year. During that time he occupied the position of an honorary lecturer; and he taught and carried on research, gave addresses to various societies, studied clinical methods (especially neurology) in London as well as in France, Holland, and Germany, and visited and made himself familiar with the methods of anatomical departments in most of the British and many of the continental schools. He carried out an important research upon the oculo-motor nucleus of *Tarsius* (*Brain*, 1923) which, taken in combination with the results obtained by Brouwer, sheds important light upon the problems of human evolution. He made an intensive study of the fossil remains of men and devoted particular attention to the Piltdown and Rhodesian remains in the British Museum He devoted much time and energy to the problems involved in the reconstruction of the Piltdown skull, and showed that when the occipital region is properly reconstituted and orientated it presents a much closer analogy to the condition found in the new-born African anthropoids than does any other human skull. By demonstrating that there is no disharmony between skull and jaw he has eliminated the chief factor in the controversy that had been raging for ten years before his work was done. His monograph on the Piltdown problem, written in 1922, has not yet been published. During the short time he spent with Dr. Ariëns Kappers in Amsterdam, he completed an investigation on the forebrain of apteryx (*Koninklijke Akademie van Wetenschappen te Amsterdam*, 1924), for which he was awarded the M.D. degree of the University of Sydney and the Unviersity medal.

On his way back to Australia he spent nearly three months visiting American and Canadian medical schools, and not only acquired a knowledge of the scientific workers and their methods, but also rendered a great service by expounding in lectures and demonstrations the meaning of recent anatomical and neurological work in England. In particular he did a great deal toward making Dr. Henry Head's work on aphasia understood. On his return to Australia he was made full professor of anatomy, being given the Challis Chair, which Prof. Wilson had formerly occupied; and he set to work to introduce the far-reaching changes incidental to the restoration of histology to the department of anatomy. With the experience gained in his pilgrimage abroad he came to exercise an influence in the medical school and University, worshipped by the students and trusted implicitly by his colleagues.

But the heavy work which these things involved did not prevent him from embarking upon a new and most formidable task, the experimental investigation of the problems of muscular tone, the solution of which had hitherto defied the leading physiologists and neurologists. He attacked this intricate conundrum with confidence and courage. His experimental work upon the effects of section of the spinal cord gave him technical experience and practice in observing the effects of lesions of the nervous system; his association with Prof. Kulchitsky at University College had given him an exact and certain knowledge of new facts relating to the sympathetic innervation of striated muscle which were of fundamental importance in the attempt to solve his problem; and his experience of the work at Queen Square, the researches of Dr. Henry Head, and Prof. Stopford's work in Manchester, strengthened his assurance boldly to attack the problem. He had explored the field of neurology and acquired the wider vision; he had acquired the experience of solving his own problems and of seeing other people solve theirs; he was ready to defy armchair critics and boldly to attempt the solution of he enigma of muscle tone.

Work on Spastic Paraplegia.

For several years Mr. Royle had been endeavouring to devise some means of alleviating spastic paraplegia. He had tried the usual surgical procedures on human patients and by experiments on animals tried to discover some new operations, without much success. He put his difficulties before Hunter on the latter's return to Australia. Hunter showed him some of Kulchitsky's histological preparations which revealed quite clearly that, contrary to the opinion expressed by Boeke and Aghdur, the sympathetic fibres to striated muscle did not go to the same muscle-fibres as the medullated nerves. He suggested that they should cut the sympathetic supply to an animal's limb and study the result. They discovered that section of the sympathetic did not destroy tone, nor even necessarily reduce it. The change in tone was qualitative rather than quantitative. That aspect of tone which Sherrington calls "plastic" is the function of those muscle-fibres innervated by the sympathetic: whereas "contractile tone" (as Langelaan has called it) is a function of the voluntary and contractile fibres innervated by medullated somatic nerves and is therefore not diminished by section of the sympathetic nerves. This fact is the principle that underlies the surgical operation which Hunter suggested (and of which he devised the technique) for the alleviation of those cases of spastic paraplegia due to an excess of plastic tone, but *not* for those in which the contractile tone alone is responsible for the spastic condition. In the hands of Royle this operation has yielded results which must seem incredible to those who have not witnessed them. It has placed in the hands of the surgeon a technique which is destined to relieve a considerable group of sufferers from spastic troubles not only of voluntary muscles, but also of visceral muscles, such as those of the stomach and intestine, the bladder, &c.

But Hunter has extended the field of his experimental investigations and has studied the nature of the proprioceptive reflex arcs that are concerned with the maintenance of the two varieties of tone. Deiter's nucleus and the vestibulo-spinal tract form integral parts of the somatic arc regulating contractile tone: whereas the ponto-spinal tract (Collier and Farquhar Buzzard) is an essential part of the sympathetic proprioceptive arc regulating plastic tone. His investigations have also shed a new light upon the rôle of the frontal cortex, the corpus striatum, the red nucleus, the substantia nigra, and the cerebellum as influences affecting tone. Hunter and Royle were invited to New York to deliver (Oct. 20th) the John B. Murphy oration on their work (see *Medicine, Surgery and Gynæcology*, December, 1924), and they gave demonstrations in many of the great medical centres of the United States and Canada. Hunter then came to England to expound the outcome of his work and to meet those who criticise his results.

By a tragic fate he was struck down in the very week when he had hoped to demonstrate to those best qualified to appreciate it the new vision of neuromuscular function created by his genius and insight. He died on Dec. 10th at University College Hospital of enteric fever contracted before his arrival in England. He was so absorbed in the mission that had brought him to England as to be unconscious of the gravity of the illness from which he was suffering. The last lecture he gave was delivered in the anatomy theatre in Cambridge on Dec. 5th, the department of the master who had played so large a part in guiding his life and shaping his aims. To those who have come under the spell of his genius and learned the truth of the teaching for which he has given his life it must ever remain a duty and privelege to expound his work, in the effort to convince others of its truth and to extend its applications by experiment and clinical application.

The Services.

ROYAL ARMY MEDICAL CORPS.

Maj. W. W. Browne to be Lt.-Col., vice Lt.-Col. and Bt. Col. G. J. A. Ormsby, promoted.

Maj. G. A. K. H. Reed to be Lt.-Col., vice Lt.-Col. A. W. Sampey, decd.

Maj. and Bt. Lt.-Col. J. M. H. Conway to be Lt.-Col., vice Lt.-Col. H. M. Morton, to retd. pay.

Maj. S. M. W. Meadows to be Lt.-Col., vice Lt.-Col. A. D. Waring.

Capts. to be Majs.: J. Hare and E. U. Russell.

Lt. R. Murphy to be Capt.

Lts. (on prob.) J. R. A. Madgwick and K. Lumsden resign their commns.

TERRITORIAL ARMY.

Maj. (Prov.) J. Kinnear is confirmed in his rank.

Sanitary Companies.—Capt. J. B. McGovern, from Hampshire Regt., to be Capt.

Supernumerary for Service with O.T.C.—Lt. N. F. C. Burgess, from Gen. List, T.A., to be Lt., for service with the Medical Unit, University of London, O.T.C.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. D. H. Scott resigns his commn. and retains the rank of Maj.

INDIAN MEDICAL SERVICE.

Lt. R. McRobert (prov.) to be Capt.

Capt. W. H. Critien and Lt. Ambika Prasad Trivedi relinquish their tempry. commns.

ROYAL EAST SUSSEX HOSPITAL.—Without any regard to the fact that this new hospital at Hastings is a threefold building with special new services, as compared with the old building evacuated in November last year, rumours have been current that the hospital was being run on more expensive lines than was absolutely necessary. The transfer from the old building to the new involved extra expenditures, some of which were foreseen and some unforeseen, and the balance-sheet disclosed an increase in the outgoings of some £3000. At the last annual meeting the governors appointed a committee of investigation, whose report, which has just been presented, shows that the rumours were quite groundless. The satisfactory nature of the report is proving a useful stimulus to the special effort that is being made in Hastings and the district served by the hospital to liquidate a debt which still amounts to £6000.

Correspondence.

"Audi alteram partem."

EPSOM COLLEGE.

To the Editor of The Lancet.

Sir.—With the approach of Christmas, a season in which humanity at large relaxes its purse-strings, I ask your readers to bear patiently with me while I expound to them the work and the needs of one of the great medical charities.

The Royal Medical Foundation of Epsom College exists (*a*) to give pensions to 50 aged or disabled medical men or their widows, and (*b*) to provide, free of charge, a good public school education, together with clothing, maintenance and pocket-money, to 50 sons of deceased or disabled medical men. The Medical Foundation, so far as it is educational, is part and parcel of Epsom College, which is a public school open to all, but aiming especially, according to the intentions of its founder, at affording to the sons of medical men generally a school education at as near cost price as possible. Generous benefactions have augmented the value of many pensions, and increased their number, so that last year the College bestowed no less than 166. That alone alleviates a sensible part of the destitution that befalls the unlucky in our profession as in any other. But the part relieved is not nearly large enough, and to do much more, much more money is needed.

Perhaps, however, it is our educational work that awakens the warmest and widest sympathy. There is very keen and widespread competition for the Foundation Scholarships, which have given to so many needy boys a start in life, open to them in no other way. The expenditure on these has been greatly increased owing to the circumstances of the war and growing educational needs.

To those who may catch sight of this letter I appeal to set it aside for perusal after a satisfying Christmas dinner; to sit down then in an easy chair with a pipe, and with closed eyes to conjure up before their minds a vision of their own wives, left widows in need, and suppliants to humankindness for the upbringing and perhaps the very bread of their own necessitous children. Then let them at once, before the image has dissolved in the welter of work, draw up to their table and write us a cheque for such a sum as the spirit has moved them to give. I warrant that the whole séance shall add to, not detract from, the gladness of their Christmas festivities.

Commercial travellers, haberdashers, and others provide tens and hundreds of thousands of pounds yearly for their needy; medical men give us less than four thousand for theirs. At present one medical practitioner in sixteen helps us; if all would help with half a guinea yearly, or better still, because easier of fulfilment, if half would help with one guinea yearly, we should multiply our present income by six. In five years the Medical Foundation, at its present dimensions, would be permanently endowed, and all wearisome begging would be at an end, to the great advantage of the College. With like support for a further five years we could go forward confidently to make our benevolent work commensurate with the full needs of the profession, and our school, with due regard to the intentions of our founder, second to none and an example to all, and an object of justifiable pride to the whole profession. So trifling an individual sacrifice for so immense a common good cries aloud for its accomplishment!

Let me first lay my own gift on that altar by trebling my own subscription, so that I may earn the right to appeal to those who already help us and can do more to do it, and to those who do not help as yet to come to our aid.

"*Cras amet qui numquam amavit, quique amavit cras amet.*"

One guinea annually, or a single donation of ten guineas, makes a governor and gives ten votes at each election in June of foundationers and pensioners, and each additional guinea annually gives ten votes more. Voting papers, with details of candidates, are sent in advance to every governor. Seldom a list that makes no direct appeal; sometimes it will be the voice of a dead friend asking help for those he has left behind.

Please send a subscription or donation to the Secretary of Epsom College, 49, Bedford-square, London, W.C. 1, who will be glad to give any information and welcomes personal visits at any time.

I have the honour to be, yours obediently,

Raymond Crawfurd, M.D.,

Dec. 4th. Chairman of the Council of Epsom College.

DENTAL DRESSERS.

To the Editor of The Lancet.

Sir,—I am instructed by the Council of the School Dentists' Society to forward you a copy of a report, issued by my Council, as a criticism to a scheme, initiated by Dr. Sidney Barwise, medical officer of health for the County of Derbyshire, for extending the duties of the school dental nurse or dresser to operative procedure.

I am, Sir, yours faithfully,

Grantley Smith,

Group Hon. Sec., The Dental Officers' Group,

Dec. 9th, 1924. Society of Medical Officers of Health.

Report.

The Council of the School Dentists' Society, while not opposed to the system of dental hygienists as carried out by Fones in the United States of America, is strongly opposed to any system by which operative dental treatment, such as the extraction or stopping of teeth, is carried out by unregistered persons. The system initiated by Fones is confined to the surface treatment of the teeth and gums, and as such is a valuable adjunct to the preventive side of school dentistry. Similarly school nurses are an invaluable and necessary part of a school dental clinic, not only in assisting the dentists, but also in looking after the children and parents before and after treatment.

The objections held by the Council to any such system as that practised in Derbyshire are as follows:—

1. There is *no* shortage of dentists to meet existing and increasing demands of local education authorities.

2. That school dental treatment being still in a developmental stage has its strongest point in that it is carried out by experienced qualified dental surgeons. It is of the utmost importance to the success of the work that the confidence of parents, children, and school teachers be gained and retained. The confidence at present reposed in dental clinics depends largely upon the fact that the work is done by experienced *dental surgeons.*

3. *Inspections in Schools.*—The fact that school inspections are carried out by the school dental officers is of vital importance to the establishment of good feeling between the schools and clinics. The inspecting officer must be prepared to answer authoritatively any question which may be addressed to him. At the same time it is impossible always to be dogmatic when asked to specify definitely what treatment is required. A diagnosis which has to be corrected subsequently is liable to undermine the confidence of parents and children, since first impressions are strong. School dentists have had occasion to complain of school medical officers in this respect.

4. The claim that the operative dental treatment carried out by dental dressers in Derbyshire is a success by no means justifies a general application of such a system. A system which is successful in a county area may be disastrous if applied to urban districts where conditions are different. At present there are many complaints in regard to school dental treatment even in the best-regulated areas, and the Society is allowed by the chief inspecting dental surgeon to the London County Council to say that in London these cases largely relate to the treatment of temporary dentition. All school dentists know that the treatment of temporary dentition is one of the most difficult branches of dental surgery. If, then, difficulties arise in the case of specially selected experienced dental surgeons, as in London clinics, complaints would certainly be much more prevalent where dental dressers are allowed to undertake the extraction and stopping of temporary teeth.

The Council regards the school dental service as an integral part of the Public Health Service. It recognises the need for extension and reform, and in particular, emphasises the importance of developing the preventive side of school dentistry. The services of dental nurses or hygienists as they are called in the United States, could be most advantageously used on the side of prevention.

AN INDICTMENT OF THE PANEL SYSTEM IN A HOSPITAL APPEAL.

To the Editor of THE LANCET.

SIR,—In a recently published appeal by Mr. George Verity, chairman of Charing Cross Hospital, appears the following passage :—

> “ Look what the Government has done with the Insurance Act—the biggest fraud ever planted on a nation since the South Sea Bubble. Millions and millions have been taken from you and what is there to show for it ? Insufficient sanatoria for consumptives, no provision for prolonged medical treatment and surgical aid, no grants for X-radiology or research. No, as far as I can make out, the people who are supposed to benefit by the Insurance Act, when they feel ill, are told to put their tongues out and be examined and then told to go home and get well again. Of course the lucky ones do get a blue pill or a black draught to help them.”

Effusions of this sort are too common in the ordinary way to attract much attention ; coming as this does from the chairman of a metropolitan hospital it can scarcely be thought other than remarkable. Mr. Verity's sweeping assertions regarding the working of the insurance system are an indictment of that section of the medical profession concerned, no less than of the system itself.

This appeal of the Charing Cross Hospital for funds rightly emphasises the beneficent and excellent work of the hospital. There is, however, some irony in this appeal on the part of a hospital proceeding to hold up to obloquy and ridicule a considerable section of the medical profession at a time when the General Medical Council is exercised in purging the profession of the vice of advertising. No doubt a greater latitude is permissible to a hospital tendering its own welfare than is accorded to members of the medical profession. When, however, Mr. Verity's appeal goes the length of stifling veracity in a barefaced manner towards one section of the medical profession, as occurs in the passage noticed above, whilst extolling elsewhere the work of a hospital staffed from that same profession, it can fairly be objected that appealing on behalf of a hospital has become objectionable and the limits of decency exceeded.—I am, Sir, yours faithfully,

Bognor, Dec. 9th, 1924. SAMUEL ARMSTRONG LANE.

MIND AND MATTER.

To the Editor of THE LANCET.

SIR,—Much of Prof. C. S. Myers's presidential address in the Section of Psychiatry, Royal Society of Medicine, as reported in THE LANCET for Nov. 29th, is so weighted with assumptions and nebulous conclusions that I venture to ask for permission to offer a few words of comment.

His view that the reflex act is posterior phylogenetically to a “ primordial mental activity which preceded the development of conscious activity,” stamps Prof. Myers either as a perpetrator of paradoxes or a hylozoist. The physical basis of life and mind is traceable through ever-increasing complexity of structure and cell dispositions, from the relatively undifferentiated protoplasm of the protists, through the simple syncytic nerve network of the sponge to the intricate synaptic nerve network of man. Hand in hand with this increase in complexity of structure goes increase in complexity of function. The reflex act asserts itself more and more, the intelligent act less and less, as we trace back the phylogenetic and ontogenetic paths. In reality, *all* action, automatic reflex, instinctive, and intelligent, must originate in an extra-organismal energy, and must, therefore, be reflex. The main differentiating feature of the so-called intelligent act is a relatively long *delay* period between the impact of the stimulus and the organism's response. Natural selection has fostered in the cortical neurone a capacity to delay, perhaps indefinitely, the response to a stimulus, the impressions from the latter being stored up ; meanwhile, by effecting contacts with other neurones in the association field, readjustments are made in the light, so to speak, of previous responses to similar stimuli. The final response to the stimulus, which may not occur for days, perhaps years, is both variable and complex ; the differences in responses to similar stimuli being governed by the effects on the organism—as recorded in its nerve-mechanism—of its previous responses to stimuli. The physical machinery of the simple reflex arc is receptor—transmitter—effector ; that of the delayed reflex arc, the arc of intelligent action, differs by the interposition between the “ receiving ” and “ transmitting ” cells of the delaying cells—the intercalary cortical neurones. The involved actions of a candidate for Parliament during a General Election differ only in degree, not in kind, from the contraction of his pupil to a strong light.

Prof. Myers regards “ consciousness ” as a selector of its environmental stimuli. Is it not rather the organism in a particular state of consciousness that is the selector ? Is it not the “ selecting ” that constitutes the consciousness ? In any case, the statement is a rash, though somewhat concealed, assault on the so-called materialistic position. Consider the conditions of existence of the human organism and it will be seen that its so-called power of selection is in reality itself determined by its very environment. It is forced to select in this or that way by circumstances. It cannot choose its own parents, nor the long lines of ancestry spreading out fanwise behind them. The race to which it belongs, the historical period of its birth, its up-bringing and education, are all beyond its powers of selection. It can modify neither its nature nor, at any rate in early life, its nurture. In its race with competitors it is frequently adversely handicapped both at the start and throughout the course. It is a victim of its physical structure ; against the insurgent demands of the ever-activating secretions of adrenals, thyroid, parathyroids, testes, ovaries, and hypophysis it is practically helpless. We know what the worthy Bishop said when he saw the convict. But what did the convict say ?

Prof. Myers is, indeed, an obscurantist where he deals with the nature of consciousness. He says :—

> “ . . . Matter is now regarded as a manifestation of electric forces, a product of activities. What now of mind ? Is not this likewise a product of activities ? . . . Are not the hidden activities of mind and matter of greater import than their more obvious products ? Are not the respectively material and mental characters of these products due ultimately to such activity itself ? ”

Now, “ activities ” can only take place in a “ something that is active,” and as we are not told what that is, whether brain-matter, ordinary matter, ultra-matter (electrons) or the hypothetical ether of space, we must, perforce, call it “ x.” (The expression “ activity of mind,” makes of “ mind ” a material entity, for, as just indicated, activity implies a something active ; but all scientific evidence points to “ mind ” being, not an entity, but a series of processes taking place in an entity—viz., the “ highest unitary system of neurones ” in the brain.) First the lecturer postulates mind as a “ product of the activity of ‘ x.’ ” Then this “ product of the activity of ‘ x ’ ” is given “ activity ”—thus at the same time making of the product an entity. Then, the “ activity of the entity, the product of the activity of ‘ x ’,” engenders another “ product.” This “ product of the activity of the entity, the product of the activity of ‘ x,’ ” is then endowed with a “ mental character.” And finally we are asked if the “ mental character of the product of the activity of the entity, the product of the activity of ‘ x,’ ” may not be due to such “ activity ” itself ? A fairly good example of the unutterable confusion resulting from circular argumentation, the abuse of words, lack of definitions, and the attempt to explain the little known in terms of the unknown. The word “ mind,” like “ life,” is a pure abstraction. Such indefinable words are out of place in scientific polemics, at any rate unless and until agreement is attained as to what is meant by the words. It would, of course, be pedantic to discountenance the use of such a word as “ mind ” in ordinary parlance, though even here it is well to remember that at best it is but a *mot de convenance* epitomising all the processes and states incident to multifarious living organisms, whether the migration of the bacillus towards a solution of malic acid, or the coördinated movements of such plants as Drosera and Venus's fly trap in preventing the escape of their insect captures, or whether the solving of mathematical problems in the cortex of man. Thinking matter we know, and not thinking matter we know, but "mind" is a figment of the distorted imagination. The practical humanitarian does not attack the abstraction "poverty," but the concretes, "man," "house," "food," "clothes," &c. It is to research work in connexion with living matter that we owe our knowledge of biology, and it is to research work in connexion with thinking, feeling, and irritable matter that we owe our knowledge of psychology. Directly the biologist or psychologist loses sight of these material entities, living, feeling, and thinking matter, and pursues such will-o'-the-wisps as "life" and "mind," he will find himself floundering in the metaphysical bog.—I am, Sir, yours faithfully,

C. MARSH BEADNELL,
Surgeon Rear-Admiral.

Royal Naval Hospital, Chatham, Dec. 13th, 1924.

THE CLINICAL SIGNIFICANCE OF CONSTIPATION.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Dec. 6th Dr. E. G. March states with unquestionable truth that intestinal toxæmia may exist without apparent stasis. Commenting on this in your current issue, Dr. A. C. Jordan writes that even in such cases evidence of stasis may be obtained by radiological examination. While I would readily accept this statement as a possibility, to regard it as an invariable fact would, in my opinion, be wrong. To look upon stasis as an invariable precursor and associate of toxæmia is to make it the essential factor in the production of that disorder, and clinical evidence does not support this view. On the one hand stasis of severe grade may exist for years without producing ill-health, while on the other toxæmic symptoms may be ushered in by an acute diarrhœic illness such as, to take an extreme example, dysentery and post-dysenteric colitis.

The essential factor in the production of intestinal (or as I should prefer to call it "colonic") toxæmia must surely be the loss of the impermeability of the wall of the colon whose special function it is to prevent the absorption of poison. Where this function remains normal no toxæmia will result, but where it is impaired toxæmia may arise; in either case in the presence or absence of stasis. No one can doubt that if the colon permits absorption the normal fæces are capable of producing toxæmia. If this view is correct, intestinal toxæmia may be regarded as arising in the following manner: (i.) The essential factor is the abnormal porosity of the colonic wall. (ii.) This loss of impermeability is due to a condition of catarrhal (or more severe) colitis. (iii.) This colitis may be due (*a*) to an infective process, or (*b*), as in the majority of cases, to chemical poisons emanating from the decomposition of stagnant fæces. Such decomposition is, of course, a bacterial process but cannot be regarded as the result of an infection in any clinical sense: frequently the fæcal organisms are normal in type and proportions.

The colitis once established, it may be maintained with its associated toxæmia by a variety of factors of which constipation is the commonest. But even in the absence of stasis the colitis may still continue from improper diet, abnormal infections, irritating purges, and possibly, for all I know to the contrary, the normal toxicity of fæces. Without going into further detail, it will be evident that the treatment of colonic toxæmia will be very different according to whether the disorder is regarded as essentially due to mechanical, infective, or inflammatory causes.

I am, Sir, yours faithfully,

Harley-street, W., Dec. 13th. REGINALD MILLER.

THE NERVOUS ELEMENT IN LUNG COLLAPSE.

To the Editor of THE LANCET.

SIR,—The admirable and instructive account by Dr. J. C. Regan, in THE LANCET for Dec. 13th, of a case of lung collapse in poliomyelitis is of great interest and importance, although the point is one that has not altogether escaped attention. Some of us have been accustomed for several years past to point out at the bedside how "basal collapse" is not at all uncommon in cases of poliomyelitis and encephalitis, and may in a few days be followed by frank signs of pneumonia, broncho-pneumonia, or bronchitis. And this initial "collapse" has been aligned clinically with the similar "inhibition" that occurs in the cases spoken of as "epidemic diaphragmatic pleurisy," "epidemic diaphragmatic spasm," and the like, and in those of epidemic hiccup associated clinically or epidemically with encephalitis lethargica. The converse problem is encountered when we recognise what Huxham described 150 years ago—paraplegia in association with peripneumony, and with what Foa taught—namely, that infiltration and œdematous swelling is to be met with in the spinal cords of persons dying with influenzal pneumonia.[1]

This clinical combination, *if looked for*, is less rare during influenzal and encephalitic prevalences than may be thought. Indeed, during 1918 I found in one ward, under the care of one physician, three cases diagnosed as pneumonia, each of which, together with bladder weakness and absence of knee-jerk, displayed, at least temporarily, flaccid palsy of both legs. This was during the height of the "encephalitis lethargica" epidemic of that year. During the last month or so I have myself had charge, in one hospital, of three patients whose initial illness was "influenzal" and who, on admission, displayed signs of "basal atelectasis," going on to broncho-pneumonia, and associated with both cerebral and spinal symptoms. I have been naïvely asked whether such cases are to be diagnosed as influenza, as pneumonia, as poliomyelitis, or as encephalitis lethargica!

The solution of both problems—that of atelectasis in poliomyelitis and encephalitis, and that of atelectasis going on to "pneumonia" in influenza—was, I believe, indicated by Graves 80 or 90 years ago, when he recognised the "nervous" element in influenza: said that in 1837 most influenzal patients died with "paralysis of the lungs"; and suggested that the peculiarities of many influenzal pulmonary complications were due to "paralysis of the eighth pair of nerves." Many have since thought as much: indeed, Peyton Blakiston and Althaus, amongst many others, founded their theory of the nervous pathology of influenza on similar considerations. And with each successive epidemic of influenza some clinician or other announces anew that, during the early stages of influenzal pneumonia, there is a curious absence of the ordinary physical signs heard over the bases of the lungs. This is why "influenzal pneumonia" so often takes the doctor unawares; and I am in the habit of teaching that, when in any case thought to be influenzal there is dyspnœa of a kind and yet "no physical signs" or, indeed, an unusual silence, then pneumonia is likely to "develop." At any rate, the occurrence of this atelectasis, in influenza with nervous symptoms, in encephalitis, and in poliomyelitis, is one more link in the proof of the incontestable and fundamental unity (as Micheli calls it) between the cases at present sorted out under these various nosological labels.

But this atelectasis has yet another interest. If we recognise it, as I think we must, as paralytic, we reach a new conception in respect of the pathology of certain pneumonias, and perhaps of much more. Instead of regarding certain pneumonias as attacks of an infective invader, we come to envisage, in certain cases, *first* an atelectasis that, being paralytic, is accompanied or followed by certain vasomotor changes, and, *secondly*, a rise into activity, a seizing of opportunity, of and by organisms till then pullulating harmlessly in the vicinity. This notion, as I tried to show in 1920,[2] links up with Mr. Benians's idea of the protective value of the mucoid layer that covers the mucous membranes. Once this mucoid layer becomes inefficient, the gates are opened for invasion by what otherwise are mere saprophytes or parasites.

---

[1] Influenza. Essays by several authors. Heinemann. 1922. P. 362.

Finally, it may be pointed out that not only in encephalitis lethargica, but in poliomyelitis (if we must maintain a distinction that every day is becoming less definable) there are often enough "visceral paralyses" other than that studied by Dr. Regan. There is the obstipation, and sometimes dilatation of the stomach; and there is the bladder palsy, too. There are, moreover, the vasomotor, pilomotor, sudoral, and salivary derangements that can hardly be ascribed to anything but "nervous" influences. Unfortunately, neurological interest seems too often exhausted when the motor and sensory and mental changes or phenomena correlated with the cerebro-spinal nervous system have been investigated. Yet, in influenza, in encephalitis lethargica, and in poliomyelitis, there is a wealth of clinical phenomena that can only be rationalised by reference to the sympathetic and para-sympathetic systems. And this further community tends to outweigh many superficial or arbitrary distinctions, and to give point to Dr. A. J. Brock's acute questionings.[3] These may be summarised thus: *How* are we to distinguish between influenza with cerebral or spinal complications, and poliomyelitis or encephalitis consequent on an influenza that, we are told, is *not* an influenza?

I am, Sir, yours faithfully,

F. G. CROOKSHANK.

Wimpole-street, W., Dec. 12th, 1924.

SUCTION IN SURGERY.

To the Editor of THE LANCET.

SIR,—I have been much interested in the suction apparatus devised by Mr. Lake and also in Mr. Whiteford's letter. My own interest in the matter had previously been aroused during a recent visit to the United States of America. During a stay at Cushing's clinic at Boston I saw suction in daily use and formed a high opinion of its advantages in neurological surgery. Heavy sponging is here out of the question owing to the thinness of the vessel walls and the vulnerability of the cerebral tissues. When a large vessel gives way in the depths of a wound in other regions, especially in the limbs, the bleeding can, as a rule, comfortably be controlled by a large swab pressed on the bleeding point and held there for some time. It is disastrous to keep lifting the swab up to see how things are getting on. In time the vessel will contract and will become more easy to seize. In the skull no such manœuvre is feasible unless the operation is extradural (as in section of the trigeminal root). If, on the other hand, a sucker is made use of, the blood may be removed practically as fast as it escapes and the wound kept dry enough for a clamp, a ligature, or a silver-clip to be early and rapidly applied; irrigation may be used along with suction if desired. The same technique I saw in use at the New York Neurological Institute and no doubt is used at many other centres. Suction is obtained by water power from a tap in the theatre, or preferably an adjoining room, with a long tube, ordinary bent glass or brass tubing as nozzles, and a glass flask to collect blood. This is the apparatus that I have personally been using. Mr. Lake's invention has the merit of portability, but in a set operating theatre the simple water Sprengel's pump has everything to recommend it. Blood may be collected (in a clean operation) and after straining may be injected back into the patient. Dr. Loyal Davis, working in Cushing's clinic, has a paper in the press on this subject. It is an advantage to use a sodium citrate solution to prevent clotting in the tube, and to dip the nozzle into this every now and again.

Only those who take a particular pride in operative technique will be especially attracted to the method. That is to say, operations can be quite well done without the aid of suction, and have been so done these many years. But no one who has seen an apparatus in use, or who has had experience with it, will doubt that very considerable advantages may be derived from it. In the mouth its uses are obvious, in the abdomen hardly less so. During operations on the biliary tract the sucker helps to keep the wound dry and to limit soiling. During intestinal resections and anastomoses one has in a suction apparatus a ready means of emptying the clamped portions of bowel, provided that the bowel contents are not too inspissated. It is not very useful in dealing with the colon or in chronic obstructions where the fæces are not sufficiently fluid to be drawn away. It may again be found useful in operations high up on the stomach and in gastro-enterostomy without clamps. In appendicular abscesses it is of the very greatest value, particularly when these are of large size. Everyone has opened an appendix abscess of such dimensions that the pus has escaped from its walled-in cavity rather more quickly than it could be mopped up or made to escape through the parietal incision. No doubt a number of unsatisfactory results after the drainage of such abscesses can be traced to the unavoidable soiling that then occurs. My practice now is to make a small incision into the cavity and insert the nozzle of the suction apparatus, so aspirating as much of the pus as possible with the abdominal wound held wide open and packed off as usual, before a finger is inserted to search for the appendix.

Experience alone can teach the precise field of usefulness for this addition to our resources. It is not a panacea, and may at times be found disappointing, but of its essential efficacy and value *to the patient* I am convinced.

I am, Sir, yours faithfully,

Manchester, Dec. 13th, 1924. GEOFFREY JEFFERSON.

MEDICAL INSPECTION OF LONDON SCHOOL CHILDREN: INCREASED MEDICAL STAFF.—Children attending public elementary schools are medically inspected (1) on entry, (2) at or about the age of 8 years, and (3) at or about the age of 12 years. While the day continuation schools were open the children were also examined at the time of leaving the elementary schools, when the choice of employment was specially considered. This fourth examination was regarded as the equivalent of an "entrance examination" to the day continuation schools and was abandoned when the compulsory schools were closed in 1922. Many representations had been made to the Education Committee of the Council that the fourth examination served a most useful purpose in revealing defects which ought to be treated before the children left school. Provision has been made in the "three-year educational programme" recently adopted by the Council for systematic examination of children immediately prior to their leaving school, in order that advice may be given on questions relating to employment and coöperation with the factory surgeon. The Education Committee now propose that the fourth examination, which will involve the inspection of about 60,000 additional children annually, shall be resumed as from April 1st, 1925, and that the question shall be reconsidered if and when the proposed Factories Bill becomes law and contains provision for the medical examination of young persons employed in factories. Extra staff of assistant medical officers and nurses will be necessary, and the additional expenditure involved will be £5600 for the first year, and ultimately £6600 annually. The Council adopted last week a series of recommendations giving effect to these proposals.

Medical News.

UNIVERSITY OF OXFORD.—In the recent examinations for the degrees of Bachelor of Medicine and Bachelor of Surgery the following candidates passed the Final Examination in the subjects named :—

Materia Medica and Pharmacology.—D. A. Abernethy, Balliol ; F. J. Bach, New Coll. ; A. V. Clemmey, Christ Church ; C. R. Croft, Trinity ; T. L. Davies, University ; J. H. Ferguson, Queen's ; E. L. Fothergill, Keble ; W. H. Hudson, Brasenose ; T. M. Ling, New Coll. ; D. Lurie, Lincoln ; S. Segal, Jesus ; C. W. Simpson, Balliol ; A. G. Wilson, Brasenose ; E. M. Wright, New Coll. ; Grace Batten, Lady Margaret Hall ; Rosaling V. Carruthers, home student ; Margaret A. L. Herbertson, home student ; Olive H. Lister, St. Hugh's ; and Irene M. Titcomb, home student.

Pathology.—D. A. Abernethy, Balliol ; F. J. Bach and R. H. B. Bettington, New Coll. ; W. B. Boone, Lincoln ; C. Charleson, Queen's ; J. C. K. Chilcott, Exeter ; J. L. Cox, Brasenose ; G. H. Crisp, Magdalen ; C. R. Croft, Trinity ; J. A. Eyres, Lincoln ; C. W. Fleming, Trinity ; J. N. C. Ford, Hertford ; A. T. Fripp and K. A. Hamilton, Christ Church ; S. Harris, Jesus ; H. O. Hopkins, Magdalen ; S. Howard and J. S. Jerome, Christ Church ; T. M. Ling, New Coll. ; C. W. Mackenzie, University ; R. G. Mathews, Queen's ; E. L. Newell, Jesus ; W. F. Howson Ray, University ; F. J. Sale, Christ Church ; J. W. de W. G. Thornton, Magdalen ; G. P. Thorold, Trinity ; O. R. Tisdall, Hertford ; E. C. Whitehall-Cooke, Queen's ; A. L. Wilkinson, Trinity ; D. O. Williams, Jesus ; and Alice D. K. Peters, St. Hugh's.

Forensic Medicine and Public Health.—C. E. G. Beveridge, New Coll ; C. P. Blacker, Balliol ; H. A. Byworth, Oriel ; T. A. J. M. Dodd, Queen's ; A. T. Fripp, Christ Church ; H. E. Harding, Oriel ; J. S. Jerome, Christ Church ; M. J. W. Minshull, Keble ; E. L. Newell, Jesus ; J. de la M. Savage, Wadham ; H. N. Stokoe, Pembroke ; R. A. Walsh, Magdalen ; D. O. Williams, Jesus ; Mathilde E. F. Bugnion, Somerville ; and Ella J. Cockram, home student.

Medicine, Surgery, and Midwifery.—M. McC. Baird, New Coll. ; R. J. Brocklehurst, University ; T. A. J. M. Dodd, Queen's ; H. E. Harding, Oriel ; J. R. B. Hern, New Coll. ; T. B. Hodgson, Queen's ; P. H. Martin, New Coll. ; J. D. Mills, Lincoln ; M. J. W. Minshull, Keble ; A. W. L. Row, Brasenose, H. N. Stokoe, Pembroke ; B. E. Tompson, Brasenose ; and Mathilde E. F. Bugnion, Somerville.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council held on Dec. 11th, Sir John Bland-Sutton, President, in the chair, diplomas of Fellow were conferred upon 25 candidates ; 105 candidates presented themselves for examination, of whom 27 passed (including three candidates who have not attained the requisite age of 25 years—Max A. Lautre, David Levi, and Clement Sturton). The following are the names and medical schools of the successful candidates :—

Haridas J. Bhatia, Bombay and London ; John T. Blackburn, Leeds and London ; Anthony Blackstock, King's Coll. ; Charles J. O. Brown, Melbourne and London ; Norman L. Capener and Frederick C. W. Capps, St. Bart.'s ; Edwin T. Cato, Melbourne and Guy's ; Daryll C. Corry, Univ. Coll. ; John Dreadon, Otago and London ; William S. D. Elder, St Andrew's and St. George's ; *Arthur J. Gardham, Middlesex and Univ. Coll. ; Charles M. Greenslade, Otago and St. Bart.'s ; Raymond V. Hennessy, Melbourne and St. Mary's ; Arthur R. Jones, Univ. Coll. ; Alan E. Lee, Melbourne ; George D. F. McFadden, Belfast and London ; B. S. Nat, St. Andrew's and Guy's ; Charles H. Osborn, Melbourne and London ; David H. Patey, Middlesex ; Alexander E, Roche, Cambridge and St. Bart.'s ; Michael J. Smyth, Dublin and St. Bart's ; Hubert W. Symons, Leeds and London ; Angus H. Whyte, Durham and London ; Frederick W. Widgery, Guy's ; and Bernard W. Williams, Oxford and St. Thomas's

* Passed examination May, 1924, now attained 25 years of age.

Diplomas of Member were conferred upon the following who have passed the requisite examinations and have complied with the by-laws :—

Margaret I. B. Cowling and Mary H. Elmitt, Royal Free ; and Cyril J. Polson, Birmingham.

Licences to practise dentistry were conferred upon the following :—

Beryl L. Allen, Royal Dental ; G. H. H. Ames, Univ. Coll. ; E. J. Andreka, Guy's ; F. G. Arnold, C. Barton, and C. S. Berrington-Stoner, Royal Dental ; N. J. Boulton, W. G. Bradbeer, and R. G. C. Broadbridge, Guy's ; B. A. Butcher and C. Buxton, Royal Dental ; H. B. M. Cahill and A. E. Cave, Guy's ; B. Chadwick, Manchester ; R. C. Churchyard, Royal Dental ; A. E. J. Cooper, London ; E. Crocker, Guy's ; Mary M. M. Davies, H. Davis-Marks, D. J. De Lima, and M. N. Denney, Royal Dental ; R. L. Denny, Guy's ; B. C. Dickinson, Univ. Coll. ; G. W. Dibble and P. Droomer, Guy's ; L. E. Edwards, W. Field, and Kate M. Fry, Royal Dental ; J. Fullwood, Birmingham ; H. W. Fynn, Royal Dental ; B. T. Gilders, London ; J. H. Gillman, Royal Dental ; S. W. Goodson and M. B. Goolding, Guy's ; V. D. Gross, Royal Dental ; R. R. Haddow, Guy's ; M. L. Harrington, Birmingham ; E. M. Harries, Guy's ; F. N. Harrison and J. P. Harrison, London ; Frances D. Harsant, Royal Dental ; M. C. Hart and J. P. Hartman, Guy's ; L. B. Hickman, Royal Dental ; H. M. Hill, Birmingham ; E. G. Hockley, Royal Dental ; N. M. Holloway, Guy's ; N. Howson, Durham ; J. Hull, Guy's ; H. A. Jenner, Royal Dental ; W. R. Keizer, London ; A. C. Kempe and H. B. Kidner, Guy's ; Jessie D. Latham, Royal Dental ; W. H. C. Lean, Guy's ; G. H. Leatherman, Harvard and Guy's ; R. L. Lee, Royal Dental ; I. Lipschitz, Guy's ; Beatrice Love, Manchester ; F. T. Lowein, A. C. Luck, and S. A. McLaren, Guy's ; L. A. T. McLean, London ; F. A. Markham, Durham, E. H. Marshall, Guy's ; G. R. Mears, London ; W. H. Meissner and W. Nicholls, Guy's ; D. H. Oliver, Durham ; E. G. Parsons, Guy's ; H. J. Pearson, Liverpool ; A. Perkins, Guy's ; F. W. Pickard, Durham ; L. G. Pickett, H. M. Pimm, F. St. J. Powley, and T. N. L. Price, Guy's ; F. H. Richardson, Leeds ; O. Sidi and H. E. Spencer-Payne, Guy's ; D. W. N. Squires and M. Stein, London ; Ellen M. Still and J. L. C. Stone, Royal Dental ; G. F. Swales, Guy's ; Maude M. Taylor and Catherine M. Thomas, Royal Dental ; R. A. Tran and W. F. C. Tucker, Guy's ; Sarah M. Twort, Univ. Coll. ; G. B. Vachha, Royal Dental ; L. Weinberg, Guy's ; H. J. Wells, London ; H. F. Wiles, Royal Dental ; W. J. Willey, London ; G. V. L. Williams, Guy's ; A. G. P. Wills, RoyalDental ; and A. C. Wilson, London.

At an ordinary meeting held recently of the Council of the College, Sir John Bland-Sutton, President, in the chair, Mr. Herbert Stringfellow Pendlebury, St. George's Hospital, was re-elected a member of the Court of Examiners. The following resolution, moved by Mr. W. E. A. Worley and seconded by Mr. M. I. Finucane, was carried with one dissentient :—

> That this thirty-sixth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation upon the Council of the College ; moreover this meeting requests that the President shall hereupon reply in detail to the two resolutions passed at the last annual meeting, and that he shall also state whether his Council has seriously considered any means whatever whereby the collective views of Members of the College may be ascertained on matters affecting their interests as Members.

In reply, the President stated that he had listened carefully to the speeches made in support of the resolution, but he failed to notice any new argument advanced beyond those set forth at previous meetings. The resolutions had been answered by his immediate predecessors in the office of President, and his own reply last year was set out in the annual report, which was sent to every member who applied for it.

UNIVERSITY OF EDINBURGH.—At the recent Final Examination for the degrees in Medicine and Surgery the following candidates were successful :—

Harry Addison, William Aitchison, San Hla Aung, Basil N. V. Bailey, Evelyne E. Baird, Mary E. Barr, George Beveridge, Albert E. Blackley, Douglas W. N. Blackmore, John F. Bland, Arthur F. Brown, Alistair J. Cameron, Lachlan G. Campbell, Victor F. T. Chan, Matthew Clouts, Robert M. Condie, John G. Cormie, Douglas J. M'Auliffe Corner, Theodore A. Crawford, Glyn A. Davies, John Douglas, Lillian R. Duffy, James N. Dugdale, Nigel Duguid, *David S. Fairweather, Archibald L. Ferguson, Robert C. Forrester, Dessedeirous Fourie, Edward A. H. Fox, Alexander Fraser, Alexander M'Leod Fraser, Daniel L. Frew, Thomas D. Glaister, James Gray, *Charles B. Grieve, David Gunn, Donald B. Guyer, William Henry, Anna M. Herdman, Chee Wing Ho, Robert Hutchinson, Benjamin James, John W. Keighley, William D. Kiernander, George M. Lamb, Alec Lazarow, Kenneth M. M'Cracken, Hugh L. Mackintosh, Angus Macrae, John C. M'Vittie, Mark S. Malone, Alexander L. Masterton, Victor W. Maxwell, Margaret M. Meikle, James F. Menzies, Robert H. Mumford, Lilian M. S. Murray (*née* Macdonald), Wallace Nelson, Richard Norton, Robert C. Ogg, Arthur Owen, William Parker, Frank S. Paterson, Alec L. Phimister, Charles K. Robertson, James A. Robertson, Elsie T. D. Robson, Robert J. Rodger, Christina B. Ross, Richard Ross, Neil D. Sanderson, Hillel Schulgasser, George Simpson, James K. Slater, Milan Sokolovitch, Malcolm E. J. Stalker, William E. Stober, Agnes E. Stothard, Graham S. Strachan, James C. Tainsh, Nicholas J. Terblanche, Alexander G. Thomson, Robert M. Thomson, Paul R. Tingley, Dorothy M. Wilkie, Bertram O. Wilkin, Joseph Wilkinson, Ada M. Woods, and Morden H. Wright.

* With distinction.

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following candidates were successful :—

FINAL MEDICAL EXAMINATION.

Part II., Medicine.—*Robert Warnock, *Alan J. Mooney, *Louis MacS. Bell, *Thomas W. May, *Isidore Rosin, John N. Atkinson, Morris Sless, Samuel M'Dermott, Thomas G. B. Crawford, Eric T. S. Rudd, Noel G. M'Auliffe, William A. Dickson, Robert E. Steen, Agnes L. Kelly, Samuel E. Magowan, Mark J. Bradlaw, John F. Wilde, Louis P. Sayers, Sylvia B. Wigoder, Herbert Birney, Robert H. M'Keag, Paul D. Piel, Dorothy I. Henry, Raymond J. G. Hyde, John G. Maguire, Cecil R. Moore, George D. Rankin, Israel Strasburg, William H. Maguire, Edward A. Bennet, Lucy E. R. Pigott, Edmund J. Walsh, Carmichael Wilson, Angel V. B. Crawford, and John M. Johnston.

Surgery.—Robert F. J. Henry, William A. Dickson, Thomas W. May, William D. Speedy, Paul N. H. Labuschagne, Robert H. M'Keag, Louis P. Sayers, John R. Bradshaw, William H. Maguire, Wilfred H. Anderson, Morris Sless, John L. Levingston, Dorothy J. Booth, Paul D. Piel, Robert W. Harte, George D. Rankin, Gordon P. Bamford, George F. Gillespie, Alfred J. Head, Robert G. F. Thompson, Edward C. Dudgeon, James L. Marshall, Jerreth Horwich, Howard St. G. M'Kenny, and John Cussen.

Midwifery.—*Augusta M. Young, *Hope Trant, *Joseph R. Gregory, *O'Donel T. D. Browne, Philip Coleman, James Dick, William R. G. Gallagher, William P. E. M'Intyre, Edward Harvey, Charles F. D. M'Caldin, Robert A. Heatley, James E. M'Cauley, Edmund J. Walsh, Carol R. J. Boland, James Craig, Gladys M. A. Lowry, Alexander D. M'Lean, Mary S. Miller, Harris Tomkin, William G. S. Maxwell, George A. Miller, William J. A. M'Mahon, Joseph V. Pincus, Dorothy A. M'Entire, Grace J. Rankin, Gordon P. Bamford, Douglas Bluett, James J. Cusack, Henry M. Nevin, James C. C. Boyle, William C. Somerville-Large, Harry Nelson, Kathleen M. Ball, Charles H. Wilson, Denis J. Cussen, Solomon Gurevitch, Norah M. Smith, and Margaret E. Pedlow.

* Passed on high marks.

FINAL DENTAL EXAMINATION.

Edward A. Kieran, Robert G. Torrens, and Olive G. Kerr.

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS.

William T. Noonan and Carriappa Appayya Nadicarianda.

UNIVERSITY OF LONDON: COMPLIMENTARY DINNER.—The Council of the University of London Graduates' Association arranged a dinner at the Hotel Victoria, Northumberland-avenue, on Dec. 15th, to celebrate Dr. E. G. Graham Little's return as Member of Parliament for the University and to meet Prof. S. L. Loney, just elected Chairman of Convocation, and Sir Josiah Stamp, elected Member of the Senate. The chair was taken by Sir William Collins, who presented to Dr. Little an illuminated souvenir to the following effect :—

> Dr. G. Graham Little, M.D., F.R.C.P. Lond., M.R.C.S. Eng., in commemoration of his election as Member of Parliament for the University of London, irrespective of party politics and in vindication of the policy of the University of London Graduates' Association for the maintenance and development alike of the teaching work of the University and of its open system of examination without intervention of external agencies unacquainted with its history and purpose. Signed : W. J. Collins, Past President ; John A. Douglas, Chairman of Executive Committee ; T. Hynes, Hon. Secretary.

Dr. Little's health was proposed by Canon J. A. Douglas, Chairman of the Association's Parliamentary Election Committee. The toast of "The Association," proposed by Sir William Collins, its founder, was responded to by Prof. Loney and Sir Josiah Stamp. The Rev. Dr. H. B. Workman proposed "The Colleges and Schools of the University," to which response was made by Mr. E. Barker, Principal of King's College, and Dr. G. Senter, Principal of Birkbeck College. Mr. Hynes proposed "The Guests," Sir StClair Thomson and Sir James Yoxall responding. Finally, Sir William Willcox proposed "The Chairman." Among the invited guests not already mentioned were Prof. Gibson Atkins, Miss Higgins (Principal of the Royal Holloway College), the Greek Minister, the Dean of Windsor, Mr. G. Murray Brumwell, Sir Arbuthnot Lane, Sir Howard Frank, Sir Israel Gollancz, and many others of academic distinction. The common message of the speakers was to the effect that the University of London is no mere examining board, no "arid abstraction," as it has been called, but a living and moving thing which gives to many men and women the only chance they have in a lifetime of obtaining advanced instruction and opportunity of culture. Those present desired, in harmony with the policy of the Association, to see the necessary reform wrought from within, producing ordered and peaceful progress. Principal Barker associated himself and the heads of other University colleges with these aims.

MEDICO-LEGAL SOCIETY.—The annual dinner of this society was held at the Holborn Restaurant, London, on Dec. 12th, the President, Lord Justice Atkin, in the chair. The toast of "Law and Medicine" was proposed by Sir William J. Collins, who said that the 17 volumes of the transactions of the society, representing the 23 years of the society's existence, showed what a large common territory there was between law and medicine to be usefully explored. Forensic medicine, he thought, had been rather neglected in the medical schools. It was hoped at the time that a great central school of medical jurisprudence might be founded in London, arising out of some of the Royal Commissions on London University, but the hope had not materialised. Sir Humphry Rolleston, President of the Royal College of Physicians of London, in reply, said that the society might discuss which, of law or medicine, was the senior profession ; he thought medicine was the second oldest profession in the world. Mr. T. R. Hughes, K.C., President of the General Council of the Bar, also responded. The Medico-Legal Society was proposed by Mr. Justice Eve. He said that it was certainly to be hoped that out of the collective wisdom of the society there would emerge a satisfactory solution of the divergent views of medicine and law upon the subject of the criminal responsibility of the mentally degenerate, because nobody could be satisfied with the position as it now existed. The Chairman, responding, referred to papers which had been read on Arsenical Poisoning, Abortion, and Proof of Childbirth, and remarked that those three subjects were of the greatest importance in the administration of justice. Anybody in the profession of a doctor, a coroner, or an advocate, he said, was not properly and adequately equipped for his task unless he had made himself acquainted with the contents of those three papers. Lord Riddell proposed "The Guests," and Sir Claude Schuster and Mr. W. H. Norton, President of the Law Society, responded. Among those present were the Master of the Apothecaries' Society, Mr. Lyndon Moore (President, Coroners' Society), Dr. L. A. Weatherly, Prof. Theo. Hyslop, Dr. A. Chadwick, Mr. W. .E. Weil, Prof. Louise McIlroy, Mr. John Webster, Dr. Roche Lynch, Dr. Godfrey Carter, Dr. T. Wilson Parry, Dr. Robert H. Cole, Dr. D. A. Cole, Sir H. C. Bennett, Dr. Agnes Savill, Sir Walter Schroder (treasurer), Dr. A. S. Woodwark, Mr. W. A. Spratling, Mr. H. B. Wells, Mr. Roland Mitchell, Dr. F. J. Waldo, Mr. Francis Agar, Mr. W. C. Williams, Dr. G. Pernet, and Mr. Ernest Goddard (secretary).

BRITISH DENTAL HOSPITAL DINNER.—The annual dinner of the hospital (formerly British Dentists' Hospital) was held at the Langham Hotel on Dec. 6th, Sir Harry Baldwin, the President, in the chair. After the usual loyal toasts and a telegram from Queen Alexandra had been read, Dr. G. Q. Lennane referred to the further extension of the work in Battersea, and said the hospital had now proved the value of its existence.

QUEEN'S UNIVERSITY (BELFAST) CLUB, LONDON.—A dance will be held by the club in the Hotel Cecil on Thursday, Jan. 15th, 1925, at 9 P.M. Tickets (to include buffet supper) will be, for members, 12*s.* 6*d.*, and members' guests, ladies, 10*s.* 6*d.* ; men, 11*s.* 6*d.* Application for tickets, to be accompanied by remittance, should be made to the hon. treasurer, 17, Wimpole-street, W.

BICENTENARY OF GUY'S HOSPITAL.—A solemn service in commemoration of the founder and other benefactors of the hospital will be held in the Cathedral Church of St. Saviour, Southwark, on Tuesday, Jan. 6th, at 12 noon. H.R.H. the Prince of Wales, President of the hospital, has signified his intention to be present.

TUBERCULOSIS SOCIETY.—Owing to Dr. F. G. Chandler's illness the meeting which was arranged for to-day (Friday) has been postponed. The next meeting of the society will, therefore, be held on Friday, Jan. 16th, when Dr. Anthony Feiling will speak on Tuberculosis of the Central Nervous System.

MIDDLESEX HOSPITAL REBUILDING SCHEME.—At a meeting of the court of governors at the Middlesex Hospital on Dec. 11th it was decided to proceed with a rebuilding policy which will probably cost £500,000. The decision has been rendered necessary by the condition of the buildings as disclosed by the architect, and it is considered more economical to rebuild than to repair. At the same meeting Sir John Bland-Sutton was elected vice-president of the hospital.

THE AUGUSTUS AND ALICE WALLER MEMORIAL.—The movement to organise a memorial to the late Dr. and Mrs. Augustus D. Waller has received considerable support. The memorial is established in recognition of Dr. and Mrs. Waller's life-long devotion to research and of the sympathetic help they always gave to other workers. The sum of £2000 has been subscribed at the London (Royal Free Hospital) School of Medicine for Women, and a trust deed has been drawn up embodying the resolutions of the final meeting of the committee and subscribers held on July 17th, 1924. The money has been handed over to the council of the medical school who are investing it as a capital sum, and who will apply the interest for purposes of scientific research. A sum of about £105 has been subscribed also for a Waller research room at St. Mary's Hospital.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The tenth meeting of the Commission was held at the Home Office on Dec. 11th, when the examination of the representatives of the Ancient Order of Foresters, Mr. W. J. Torrance, High Chief Ranger, and Mr. Stanley Duff, secretary, was continued, the following subjects being dealt with : Extension of the scope of medical benefit to cover specialist and consultant services, the provision of dental treatment as a normal benefit, restriction of the amounts supplied to cash additional benefits, the position of the deposit contributors. Thereafter the examination of the representatives of the National Conference of Industrial Assurance Approved Societies was begun. The oral evidence given at the meeting of Nov. 27th is on sale in proof form (1*s.* 6*d.*) at H.M. Stationery Office.

PEOPLE'S LEAGUE OF HEALTH.—A benefit performance in aid of this League will be given at the Palladium Theatre (by permission of the National Sunday League) on Jan. 18th, 1925, at 3 P.M.

POST-GRADUATE STUDY IN VIENNA.—The Vienna Medical Faculty has arranged an extensive series of post-graduate courses in various medical subjects, consisting of lectures and clinical demonstrations, which are held every month during the academic year. Special courses are also held in English. Full information may be obtained on application to the Kursbüro, Schlösselgasse 22, Vienna VIII.

UNIVERSITY OF LEEDS.—At the graduation ceremony held on Tuesday, Dec. 16th, during the course of the jubilee celebrations of the University, the honorary degree of Doctor of Laws was conferred on Sir Berkeley G. A. Moynihan, professor of surgery in the University. The honorary degree of Doctor of Science was conferred, in absentia, on Emeritus Prof. John Edwin Eddison, formerly professor of medicine in the University.

UNIVERSITY OF MANCHESTER.—At a recent meeting of the Council of the University it was announced that Dr. A. E. Barclay, Dr. B. A. McSwiney, and Dr. B. J. Ryrie had been elected members of the Board of the Faculty of Medicine.

MANCHESTER'S MILK-SUPPLY JOINT COMMITTEE.—At a joint meeting held last week in Manchester of the Manchester Public Health Committee, the Lancashire, Derbyshire, Cheshire, and Staffordshire branches of the Farmers' Union, the Manchester and Salford Milk Dealers' Association, and the Lancashire Milk-recording Society, the movement to secure a cleaner and better milk-supply for Manchester was carried a step farther. A joint committee consisting of two members from each of the four county branches of the Farmers' Union, two from the Milk Dealers' Association, one from each of the Milk-recording Societies of Lancashire, Cheshire, and Derbyshire, and representatives of the Public Health Committee was appointed. It was agreed that, whilst repressive measures, as expressed in ordinary legal proceedings, may have a useful effect, the best results can be obtained by willing coöperation. The Farmers' and Milk Dealers' organisation have expressed their willingness to further the scheme by every means in their power, particularly by influencing their members wherever it is necessary, and by advising and otherwise helping them to improve the conditions of milk production.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—At the annual meeting of the College held on Dec. 4th Dr. George Lovell Gulland was re-elected President for the ensuing year, and the following were elected members of Council: Sir Robert Philip, Dr. R. A. Fleming, Dr. G. M. Robertson, Dr. Claude B. Ker, and Dr. Edwin Matthew. The other office-bearers are as follows: Vice-President, Dr. J. C. Dunlop; treasurer, Sir Norman Walker; hon. librarian, Dr. Robert Thin; curator of laboratory, Sir Robert Philip; secretary, Dr. J. S. Fowler.

ROYAL INFIRMARY, EDINBURGH: NEW RADIOLOGICAL DEPARTMENT.—The new radiological department, the plans of which have recently been passed by the Dean of Guild for the City, has been designed to furnish adequate provision for the increasing demands which modern medicine and surgery make in the diagnosis and treatment of disease by physical methods. The building, of reinforced concrete, faced with stone in keeping with the rest of the infirmary buildings, will consist of two floors and a large well-lit basement. The building itself will not be of a height or in a position to overshadow any ward, and will be easily accessible from any part of the hospital. The ground floor will be devoted to radiography, and will comprise (1) a radiographic room for X ray examination of bones and joints; (2) a screening room specially adapted for investigation of gastric and intestinal function; (3) a screening room for the examination of the heart and lungs, and rooms for superficial and intensive X ray treatment. For the latter a special apparatus is to be installed, the most powerful yet designed, working at a voltage of 250,000, and it will be used mainly for treatment of cancer. In addition there are provided rooms for developing films and prints, a laboratory for research work, a large demonstration room for students, rooms in connexion with the administration of the department, together with large waiting and dressing rooms for the patients. In all radiographic rooms the walls will be made of X ray proof material, affording ample protection for both patients and workers. On the first floor provision has been made for massage and remedial exercises, in addition to electrical, radium, and artificial sunlight methods of treatment. At present these departments of treatment in the infirmary are hampered by lack of space. The basement of the building will house workshops and stores. The housing of the electric generators and motors to supply the electric current throughout the department has been specially arranged so that no noise will reach the patients. This is a new feature in an X ray department. Steam-heating will be adopted and ventilation secured by a system of mechanical extraction, which will ensure a plentiful supply of fresh air in every room. The new radiological department when completed will be the largest and most completely equipped in the country, and will meet the requirements of the infirmary for many years to come. It is estimated that the building will cost £40,000, and that the electrical and other equipment will involve an expenditure of a further sum of £12,000.

BRISTOL MEDICAL DINNER.—A dinner was held on Dec. 11th at the Grand Hotel, Bristol. Mr. W. E. Miles was the guest of the evening and Dr. A. L. Flemming presided over a company numbering some 150. The President proposed the toast of "The King" and Dr. Charles Corfield then proposed the toast of "The Guest of the Evening." He spoke of Mr. Miles's position in the front rank among those surgeons who specialise in the lower alimentary tract and of his work at the Cancer and Gordon Hospitals. Mr. Miles proposed the toast of "The Bristol Medical School" and referred to its long rôle of distinguished men. Bristol with its great traditions had nothing to fear from the future. Surgeon-Commander W. Blatchford responded for the Medical School and referred to the improvement in teaching and to the camaraderie now existing between teachers and taught in contrast with the formality of his student days. Prof. Buckmaster proposed the toast of "The President" in a humorous vein, and Dr. Flemming replied in an amusing speech. A reception was afterwards held at the University by the wives of the medical staff.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 10TH.

Debate on the Address.

THE debate on the Address in reply to the Speech from the Throne was resumed.

Sir H. SLESSER (who was Solicitor-General in the Labour Government, but who held the office without a seat in the House of Commons, which he entered for the first time at the recent General Election) said the Labour Party read in the King's Speech the desire for unity and for many things which they appreciated. But the opposite was present, too. It was present in the insistence on what they called economy, which meant relieving the taxation of certain people and failure to use the money which ought to have been derived from that taxation for social purposes. That ideal the Labour Party entirely denounced. They used economy in the Greek sense; they were all economists, but if by economy it was meant that his constituents were to continue to live in the houses in which they lived to-day; were to continue to have the medical treatment which they received to-day, and the lack of proper educational facilities was to go on in order that some wealthy gentlemen might pay 6*d.* less on super tax—if that was the Conservative programme they (the Labour party) were inexorably opposed to anything of the sort.

Major COHEN, after expressing satisfaction at seeing Major Tryon once more in the position of Minister of Pensions, said that the final awards to pensioners came into force on Jan. 1st, 1922, and between that date and the end of September, 1924, 434,907 final awards were made. Only 182,000 resulted in the granting of permanent pensions, which meant that in the remainder, 253,000 cases, the men had all been awarded pensions which were under 20 per cent. After being given allowances for a certain limited number of weeks they were wiped off the Ministry's books. He did not think that was a satisfactory state of things. If the Ministry of Pensions medical board thought a pensioner was likely to remain in his condition for the rest of his life it was not likely that they were so wrong that he would get worse within the first 12 months. The appeal, however, had to be put in in the first 12 months. It was afterwards that the man got worse and therefore the right of appeal was not worth much. Some time ago in Swansea the chief medical men in the town, coöperating with the British Legion, discussed the eligibility of these men to put in another appeal. These medical men—the most eminent in Swansea—were astounded by the fact that so many men came before them who were obviously suffering either from wounds or disease contracted during the war directly traceable to the war and who were yet not in receipt of a pension. They decided to go further into the question. An independent committee of medical men in Swansea was formed to consider the question and they came to the conclusion that there were certain disabilities which it was impossible for any medical man to say definitely would not alter. They specified the following: Organic diseases of the heart, chronic pulmonary diseases, rheumatism, gunshot wounds, and diseases of the joints. They gave it definitely as their opinion that men suffering from these diseases were more likely to get worse than better. Therefore, to say definitely that those men should be in receipt of a fixed pension would be unfair and unjust and not really what the country desired. Circular No. 30, issued in May, 1924, attempted to deal with this problem and on reading it through it at first seemed quite fair, but in reality it was not. He claimed that all final decisions should be under the jurisdiction of an independent tribunal.

THURSDAY, DEC. 11TH.

Ex-Service Men in Lunatic Asylums.

Sir **HERBERT NIELD** asked the Minister of Pensions whether he was aware that a statement had been made by the Ex-Services Welfare Society that 6000 ex-Service men were at present inmates of pauper lunatic asylums and in daily contact with the ordinary inmates of such institutions, most of whom were incurable; that the cost of maintaining these men was on an average 5*s.* 5*d.* per head, and in some cases less than 6*d.* per day per patient, and the average cost of surgery and dispensary treatment 2*d.* per week; and would he give earnest consideration to the matter and frame a scheme under which these men might be removed to more congenial surroundings, where they might have more chance of recovery and receive such treatment as would recognise their right to the greatest measure of comfort, such as would be afforded by segregation, in recognition of their past service.—Major G. C. **TRYON** replied: I am aware of the statement referred to in the first part of the question, and I would add that I deprecate most strongly the term applied to these institutions. Public asylums in this country are carried on at the charge of the county and borough rates and under the control of the county and borough authorities, and the description of them as pauper lunatic asylums on the ground that a proportion of the patients in them are to some extent supported by boards of guardians, is very gravely misleading and needlessly offensive, not only to the relatives of ex-Service men, but to those of the many thousands of civilian patients. Ex-Service men, whose unfortunate mental condition has been found to be due to their war service, or aggravated thereby, and who, therefore, as certified patients are, under the general law of the land, in public asylums, are there on the footing of private patients and the entire cost of their treatment is defrayed by my department. That cost amounts on the average not to the figure stated, but to 25*s.* a week, in addition to which allowances are paid both to the men themselves and to their families. With regard to the latter part of the question, I would point out that the Government made provision in 1923 for separate special accommodation for those cases in which they were medically advised that a chance of recovery or improvement was offered by special treatment in the form of occupational training and instruction. For this purpose, two institutions were opened in which at the present time 415 cases are accommodated. I would add that all cases of ex-Service men in public asylums are under periodical inspection by medical officers of the Ministry in conjunction with those of the Board of Control, and every case that appears at all suitable for treatment in some other class of institution is removed from the asylum.

Time Limit for Pension Appeals.

Lieut.-Colonel Sir **JOSEPH NALL** asked the Minister of Pensions whether he could now announce the abolition or considerable extension of the time limit allowed in which appeals from the Ministry's decision could be made to the Pensions Appeal Tribunal.—Major **TRYON** replied: I fear that I should have no authority to adopt the course suggested because the time limit is laid down by statute. At the same time, I would remind my hon. and gallant friend that an arrangement, whereby cases in which an appellant is shown to have been prevented by some unavoidable cause in making his appeal in the time allowed are put to the tribunal, is in operation.

Minimum Standard of Fat Content.

Mr. **HURD** asked the Minister of Agriculture when he proposed to take steps for the imposition of a legal minimum standard of fat content applicable to both home-produced and imported whole-milk cheese and cream, as recommended by the Linlithgow Committee.—Mr. **WOOD** replied: The extensive taking of samples of various kinds of cheese was considered a necessary preliminary to the consideration of this recommendation. The last of these samples are now being analysed by the Government laboratory, and when a report is received I shall be in a better position to decide what further action, if any, is desirable.

MONDAY, DEC. 15TH.

British Station Hospital Committee in India.

Sir **PHILIP RICHARDSON** asked the Under Secretary of State for India whether any report had been received from India as to giving effect to the recommendations of the British Station Hospital Committee, under the chairmanship of Surgeon-General Sir G. H. Makins, in 1918; and when he expected to take action to improve the standard of comfort and accommodation in the hospitals for British troops in India.—Sir P. **SASSOON** replied: A report has been asked for but has not yet been received. I will inform my hon. friend when it arrives, and perhaps he will allow me to await it before making a statement in reply to the last part of the question.

Indian Medical Service.

Lieut.-Colonel **FREMANTLE** asked the Under Secretary of State for India whether the Government proposed to adopt the recommendations of the Lee Commission on the Superior Civil Services in India as to the abolition of the Indian Medical Service and the provincialisation of civil medical service.—Sir P. **SASSOON** replied: No decision has yet been reached on the recommendations of the Lee Commission as to the organisation of the medical services in India.

Mr. **WARDLAW-MILNE** asked the Under Secretary of State for India whether the official announcement recently made that His Majesty's Government had accepted the substance of the recommendations of the Lee Commission included their acceptance of the proposals regarding the Indian medical services.—Sir P. **SASSOON** replied: The recent announcement does not refer to the Commission's proposals for the reorganisation of the medical services in India, which, as I have just stated, are still under consideration.

Board of Control and Patients' Appeals.

Mr. **GRIFFITHS** asked the Minister of Health if his attention had been drawn to the fact that the Board of Control discovered by careful inquiry and reported that during the one year 1922 at least 31 patients were deprived of their right of appeal to a magistrate through misdemeanour on the part of medical superintendents; and, since this right conferred in Section 8 was the most important legal safeguard in the Lunacy Act, would he cause similar careful inquiry to be made in regard to the number of similar acts of negligence which had occurred in 1923.—Mr. **NEVILLE CHAMBERLAIN** replied: It is now the practice of the Board of Control to make inquiry regarding each individual private patient admitted to an institution without having been seen by a judicial authority. No instance has come to their notice of a failure to comply with the requirements of Section 8 of the Lunacy Act, 1890, during the year 1923.

Naval Surgeons and Non-attributability.

Sir **BERTRAM FALLE** asked the Parliamentary Secretary to the Admiralty if he would say when it was proposed to set up an independent tribunal to whom naval invalided ratings might appeal against the decisions of naval surgeons as to non-attributability or degree of disablement.—Mr. **DAVIDSON** replied: This matter has been very carefully considered and it has been decided not to set up an appeals tribunal for post-war invaliding cases.

Adulterated and Impure Food.

Mr. **CLARRY** asked the Minister of Health if he was now prepared to make a pronouncement with regard to proceedings aimed at regulations for the better protection of the public against the adulteration and selling of impure food. —Sir **KINGSLEY WOOD** (Parliamentary Secretary to the Ministry of Health) replied: The matter is engaging my right hon. friend's attention, and he is considering, in the first instance, the steps necessary to give effect to the principal recommendations of the Departmental Committee which has recently reported.

Board of Control and Patients' Certificates.

Mr. **GRIFFITHS** asked the Minister of Health if he would cause inquiry to be made by the Board of Control into the number of instances among the private patients' certificates sent up to them for scrutiny during the year 1923 in which the patients' own doctor did not certify and no reason was given for his not having been called in; and since, according to Section 31 of the Lunacy Act, this reason was to be deemed a part of the petition, would the Board undertake in future to refuse their endorsement to any document not containing this reason.—Sir **KINGSLEY WOOD** replied: It is the practice of the Board of Control to return all reception documents which do not comply fully with the requirements of Section 31 of the Lunacy Act, 1890, in order that the necessary information may be inserted. There would, therefore, be no purpose in making an inquiry as suggested by the hon. Member.

Tuesday, Dec. 16th.

Women Students at St. Mary's Hospital.

Mr. Benjamin Smith asked the Chancellor of the Exchequer whether any grants had been made by the University Grants Commission to the board of management of St. Mary's Hospital; if so, whether he was aware that this board of management had decided to exclude women students; and whether, before any further grants were made to the hospital, representations would be made to the board of management with regard to this decision.—Mr. Churchill replied: The answer to the first two parts of the question is in the affirmative. As regard the third part I must point out that the admission of students to university institutions is essentially a matter for decision by the academic authorities, with whose autonomy the Government desire to interfere as little as possible, and I see no reason for taking such action as is suggested. There is no evidence that the facilities for the medical education of women in London are inadequate. The London School of Medicine for Women, which receives a substantial grant from the Government, is a large school, which admits only women, and women students are also admitted to the medical schools attached to King's College, University College, Charing Cross, Westminster, and Royal Dental Hospitals.

Pensioners and Pulmonary Tuberculosis.

Mr. Thomas Kennedy asked the Minister of Pensions if he was satisfied that the period of 12 months after discharge allowed as a condition of entitlement to pension for the first-known manifestation of pulmonary tuberculosis was sufficiently long; and if, in cases where there was a doubt as to whether such a disability was due to or aggravated by war service, claimants or their dependants would in future get the benefit of the doubt.—Lieut.-Colonel G. F. Stanley (Parliamentary Secretary to the Ministry of Pensions) replied: The period referred to which was arrived at on the advice of the highest medical authorities was an indication that this disease may remain latent for a considerable time and is merely a definition of the period of time within which the first symptoms of the disease could appear and yet the disease be held to have commenced during the war service. In dealing with claims of compensation in respect of this disease, full weight is, however, always given to evidence indicating that the disease was present at an earlier date, although not diagnosed as such until possibly some considerable time after the period referred to.

Deputy Commissioners of Medical Services.

Colonel Perkins asked the Minister of Pensions the number of deputy commissioners of medical services whose tenure of office had been terminated since January, 1924, who had received notice that their services would not be required after the expiration of their contracts; how many of these were disabled or had war service; whether any other men with no war disability and less service had been retained; and whether he would investigate any cases which might be brought to his notice.—Major Tryon replied: Since January, 1924, 18 deputy commissioners of medical services have been notified that their whole-time employment will not be continued after April 30th, 1925. Of this number 15 served in H.M. Forces during the Great War, 12 overseas and 3 on home service, and 4 are disabled. Of the three non-service officers, one is a retired naval officer who was over age during the Great War. The staff, numbering 203 not under notice, include nine medical officers with no war service and a number who sustained no disability during their war service, but I am satisfied that the selection was made as the result of comparison of the claims of all members of the medical staff affected in which war service and war disability were given due weight. It was necessary, however, that comparative suitability and aptitude for the particular kind of work to be performed should be the paramount consideration, and in view of the importance of the medical side of the pensions administration it was impossible that there should be any relaxation of this rule.

Disinfection of Casual Wards.

Mr. Benjamin Smith asked the Minister of Health whether any of the casual wards which were stated in the recent survey of the casual wards outside London to be poor as to cleanliness, or in bad condition generally, were infested with lice; and, if so, would he take immediate steps to compel the guardians to provide sufficient means of disinfection, and to bring the wards up to the standard of those other wards where the cleanliness was declared in the survey to be good.—Sir Kingsley Wood replied: My right hon. friend is not aware of any case in which casual wards are infested with lice. The second part of the question, therefore, does not arise.

Appointments.

Campbell, R. D., M.B., Ch.B. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Kirriemuir District of the County of Forfar.

Davies, T. B., M.D., B.S. Lond., M.R.C.P. Lond., F.R.C.S. Eng., Assistant Surgeon for Diseases of Women, West London Hospital.

Goodwin, A., M.D. Lond., F.R.C.S. Eng. and Edin., Assistant Obstetric Surgeon, Westminster Hospital.

Guthrie, T., M.B., B.C. Camb., F.R.C.S. Eng., Honorary Lecturer in Laryngology, University of Liverpool.

Paterson, D. H., M.B., Ch.B. Edin., M.R.C.P. Lond., Physician to the Department for Diseases of Children, Westminster Hospital.

Wood, W. H., M.D., Ch.B. Manch., Derby Chair of Anatomy in the University of Liverpool.

St. John's Hospital for Diseases of the Skin, Leicester-square: Dore, S. E., M.D. Camb., F.R.C.P. Lond., Honorary Physician; and Roxburgh, A. C., M.D. Camb., M.R.C.P. Lond., Honorary Assistant Physician.

Vacancies.

For further information refer to the advertisement columns.

Adelaide University.—Marks Lectureship in Applied Physiology and Sheridan Fellowship. £750.

All Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, S.W.—Res. Sen. H.S. at rate of £200. Also Jun. H.S. at rate of £100.

Birmingham City Fever Hospital, Lodge-road.—Asst. M.O. £400.

Bradford City.—Sen. Dent. O. £650. Also Asst. Sch. Dentist. £450 and bonus.

Chelsea Hospital for Women, Arthur-street, Chelsea, S.W.—S. Also Pathologist (gynæcological). £40.

Dumfries and Galloway Royal Infirmary.—Jun. R.M.O. £125.

Eastbourne, Princess Alice Hospital—Res. H.S. at rate of £175.

L.C.C. Mental Hospital Service.—Junior Asst. M.O. £432.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. at rate of £150.

Malayan Medical Service.—Medical and Health Officers. See advt. for salaries.

Merthyr General Hospital, Merthyr Tydfil.—Res. H.S. at rate of £100.

Royal Army Medical Corps.—Commissions.

Royal College of Physicians, Pall Mall East.—Milroy Lecturer.

St. Bartholomew's Hospital.—Assts. to the Surg. and Med. Professional Units.

St. Mary's Hospital, W.—Med. Supt. £400.

St. Pancras Dispensary, 39, Oakley-square, N.W.—Hon. P. and Hon. Ophth. S.

South Shields, Ingham Infirmary.—Sen. H.S. £200.

Weir Hospital, Grove-road, Balham, S.W.—Asst. R.M.O. £100.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Ryde, Isle of Wight; Braemar, Aberdeen; Ayton, Berwick; and Leeds, South, Yorks.

Births, Marriages, and Deaths.

BIRTHS.

David.—On Dec. 9th, at Gwestfa, Manordilo, South Wales, the wife of Dr. T. W. David, of a son.

Elvery.—On Dec. 6th, at Karachi, the wife of Major Philip Elvery, M.C., D.S.O., R.A.M.C., of a daughter.

Twort.—On Dec. 7th, at The Wilderness, Camberley, the wife of Dr. F. W. Twort, of the Brown Institution, London, of a daughter.

Wootton.—On Dec. 6th, at Ewell Colony, Epsom, the wife of Dr. L. H. Wootton, of a daughter.

DEATHS.

Brewer.—On Dec. 11th, suddenly, William Kenneth Brewer, M.R.C.S., L.R.C.P. Lond., aged 57, of 39, Belsize Park, N.W. 3, dearly loved husband of Mildred Magnet Brewer.

Paxton.—On Dec. 9th, at South Pallant, Chichester, Francis Valentine Paxton, J.P., M.B.Oxf., M.R.C.P., aged 88 years.

Scott.—On Dec. 5th, in Paris, Gerard Affleck Scott, M.B., C.M. Edin., of Ballarat, Australia.

IN MEMORIAM.

Swan.—In memory of Charles Atkin Swan, O.B.E., B.A. Oxf., M.B., B.Ch., M.R.C.S., L.R.C.P. Lond., F.R.G.S., F.R.P.S. (late President), Founder of the first Flying Corps Hospital in London, the beloved husband of Veronica, who passed on Dec. 13th, 1923, aged 60 years, fortified with all the Rites of Holy Church. R.I.P.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

ALASTRIM AND VARIOLA.*

Note Presented to the Committee of the Office International d'Hygiène Publique in its Session of October, 1924,

BY PROF. RICARDO JORGE (LISBON),
DELEGATE FOR PORTUGAL.

WHEN in May last I drew attention to the appearance of alastrim in the island of San Miguel, as a result of infection coming from Martinique, I permitted myself to make certain summarising observations on this disease, not only as being interesting in itself and much more so by its affinities, but also as one which, after having bulked largely in the chronicles of exotic pathology, has now placed its feet on European territory where it seemingly intends to entrench itself. I now ask leave to return to a subject of which so much is now being heard, not only at meetings of academies of medicine, but also in the columns of the medical press and in official reports. The "alastrim question" must needs be topical; it is a present actuality.

The basis of this question, on which opinions are divided, sometimes with a certain asperity, is to know where to place this disease in the system of infectious pathology. The discordant opinions would not be thrown at each other with so much energy if we had to deal merely with a simple question of nosological classification. The discussion is animated because the classification of alastrim touches on the diagnosis and prevention of an epidemic condition of such primary importance as variola, a disease subject to compulsory declaration and to a compulsory system of prevention, the strict application of which has led to an agitation in certain countries culminating in the clamorous doctrines of freedom from prophylaxis which are preached by antivaccinators and Christian Scientists.

Unicists and Dualists.

While some, the *unicists*, desire to see in alastrim merely an expression of variola, others, the *dualists*, persist in believing it a species sui generis, autonomous and independent. Now if the latter are right, if we have concern with a new morbid entity—whose character is basically non-variolic and only varioliform to the extent that varicella is varioliform—all these administrative requirements would be beside the mark. If, on the other hand, alastrim is only a deceptive label, if it ought to be regarded and considered as substantially identical with small-pox or as an indefinite form of small-pox, then all the rigid measures of prophylaxis are applicable and should be required. It is, however, the gravity of the disease which justifies the severe measures taken against small-pox—a gravity which is no less for mild cases which by their infection can engender very severe and fatal cases. And inasmuch as alastrim, looked at from the most comprehensive point of view of epidemiology, in circumstances collective and individual, maintains almost an ideal benignity, the peoples may consider that the imposition of all this heavy weight of preventive administration is lacking in the moral force which should be behind it.

It is not clear to the public why a patient covered with a varicella eruption should be left peaceably at home, while another who appears quite like him (except, perhaps, that his rash is so slight and its elements so few that one can count them) is obliged to be isolated in a hospital from which he will return after a similar uneventful cure. This is what happened last year on the occasion of the epidemic at Gloucester which was considered to be "*mild small-pox*" but was so innocuous that in a total series of about 500 cases it caused only three deaths, and even these could not be represented as entirely the result of the disease, as other causes of death also operated. Similarly, in Switzerland, where according to the communication made to us by Dr. Carrière in 1922, "the public even invoked the mildness of the small-pox as a reason for refusing vaccination, alleging that the consequences of the latter could be more disagreeable than those of the disease which it was claimed to prevent."

Practical Bearing of the Controversy.

This contrast has led me to venture on some reflections which, though they may seem unusual at first sight and possibly a little dangerous, appear to merit consideration and have not so far been introduced into the discussion.

If the position be accepted that the disease with which we are dealing is small-pox—so "small" that it neither increases in virulence during extensive epidemics nor during its smallest endemic manifestations, then not only would it not be worth while to fight against the contagion, but one even ought to encourage it. In the villages of my country when epidemic measles attacks a house where there are numerous children, the mother considers that it is her obvious course to bring them all together in order that the disease may be communicated from the sick child to the healthy ones. Now for measles this course entails the danger of respiratory complications, whereas here there is scarcely any appreciable risk. The infection is so slight that it is hardly even necessary to call in the doctor; the disease, so to speak, kills nobody; it leaves no traces behind it; the face is not disfigured. Further, on the hypothesis of identity, a definite advantage will be gained; the victim, if one may call him a victim, has obtained a real profit since he remains immunised against all forms of small-pox more thoroughly and to a more durable extent than if he had been vaccinated with cow-pox. There would not even be any valid reason to check the diffusion of a variola so mild as this by means of Jennerian vaccination, since the epidemic attack itself will form a guarantee of protection against the malignity of severe small-pox which is better and as safe as that furnished by vaccination.

This manner of view may be pursued a little further. Inoculation of the small-pox virus itself was formerly applied as a preventive measure against the scourge. It was hoped thus to obtain for the inoculated person an acquired immunity by means of a mild attack which would protect him against severe and fatal attacks. It was a proceeding which was precarious and dangerous, as it not only artificially propagated the epidemic but also sometimes produced, not the discrete and benign form which was desired, but the formidable variety, confluent and lethal—the disease against which it was intended to protect. This variolisation has yielded place to Jennerian vaccination, but the protection of the latter is in general less effective and less durable than that of the former, to such an extent that cow-pox inoculation has to be repeated at intervals in order that immunity may be maintained. But what if one had at disposal a virus whose effects are safely attenuated, such as the alastrim virus is supposed to be? Might one not think of reviving the historic procedure of variolisation? Even to the dualist this suggestion would still be admissible, since it is generally believed that there is a difference between the virus of small-pox and of cow-pox although they immunise one against the other reciprocally. There would be room for experiments in this sense if we were not limited to the customary laboratory animals. Less than a century ago the comparison of the effects of variola and vaccinia was made by experimentation *in anima nobili*. As much from the point of view of scientific progress as from the advantage to be obtained for mankind, it is regrettable that such experiments, under suitably determined conditions, are not now becoming permissible and practicable whether for this particular infectious malady or for others which are special to the human species. It would be the only means of arriving at a solution of many questions requiring an elucidation at present very ineffectively provided by the use of monkeys, chosen in default of something better as the animals closest to the human whom they very imperfectly replace in the experimental field of infectious pathology.

In what has just been said, I have desired to give an outline of the much discussed problem of the "placing" of this new epidemic malady without making any assertion of my own, and by using the method of antithesis. Until the final solution has been attained—and it will always be incomplete until the microbic agents of variola and similar infections are discovered—it is at least useful to collect material and to test the notions which can be extracted from it. The documentation may be said to be abundant. To the work already published both before and after the war, among which are included classics like those of Korte in 1904 in South Africa and of Ribas in Brazil in 1910, must be added a great harvest of contributions of all kinds since 1919, clinical, epidemiological, and experimental, and coming from all parts of the world; for the disease is tending to become ubiquitous and wherever it appears it is not long in attracting attention by its peculiarity. In adding to these data those collected in Portugal, we have attempted the arduous task of making a kind of methodical and critical review of this material. For the latter I owe special thanks to Messrs. Raynaud, Buchanan, Carrière, Gouzien, Chagas, and Cumpston, as well as to Messrs. de Cazotte and Marignac, all of whom have given me bibliographical indications or have procured documents for me. Mr. Armand Netter has also supplied me with useful information and assisted me in the preparation of this memoir.

I. TERMINOLOGY.

The term *alastrim* has superseded other synonyms, being now almost universally employed. It is a Brazilian word derived from the Portuguese *alastrar* meaning "something which burns like tinder, scatters, spreads from place to place." In Portugal we have a similar word, *andaço* from

---

* Translated (with slight abridgment and insertion of cross-headings) from the Bulletin of the Office International d'Hygiène Publique, Paris, October, 1924, tome xvi., No. 10.

andar, "something which travels," but it is applied to any kind of spreading epidemic. The word *alastrim* first obtained currency in Ribas's monograph, published in 1910, a fundamental contribution to our knowledge of the disease; the importance of Ribas's work and the euphony of the term have combined to favour its acceptance. I may note in passing that to keep the original sound derivatives should be spelt *alastrinic*, &c., and not "*alastrimic.*" The term is of popular origin like those of so many other eruptive fevers, the characteristics of which are so striking that the public determines their existence intuitively. It was first used by the natives in the interior of the province of Bahia, whence the disease and its name spread to the Southern States of Brazil.

Another name for the disease, also of the people, had received prior recognition in medical literature. This was *amaas*, a native word of South Africa, gathered by Korte, and utilised by him in the paper of 1904 in which he first claimed that the disease was a distinct entity. This Kaffir word signifies "milk in fermentation"; others contend, however, that it is a corruption of the Dutch *masels* or *masellen*, and corresponds to the English *measles* (Mitchell). In spite of its priority, however, it has not found general favour, perhaps because of its rather harsh sound; it is, of course, still employed by Anglo-African doctors.

An exanthematic fever with a vesiculo-pustular rash, *alastrim* is now grouped with the series of "pox" diseases, taking its place with *small-pox* and *chicken-pox*, which it resembles so closely that it is sometimes called *variola-varicella*, or *varioloid-varicella* in order to express this double analogy. It has also been given the name *milk-pox* and *white-pox* on account of the white and milky appearance of the contents of the vesicles at a certain stage in their development. In England, where it is generally regarded as only a stunted branch of the old small-pox stem, it is usually called *mild small-pox*.

Finally, in order to emphasise this relationship, without prejudging in any way the question of identity, the name *para-variola* (Beaurepaire-Aragao) or *para-small-pox* (Garrow) has been proposed in accordance with the terminology already adopted for other varieties of infection. The Brazilian doctor includes varicella as well as alastrim amongst the para-variolas; but the former has the right to a completely independent category since the facts of epidemiology and immunology prove beyond doubt that though it resembles variola it has no relationship to that disease. The use of the term *para-variola* seems to me excellent, but I would reserve it for the exotic varieties, alastrim and amaas, for the so-called white or mild small-pox, or, indeed, for all the different variations of ordinary small-pox, without prejudice to the question of their identity or disparity.

To those who refuse to recognise "alastrim" and adhere firmly to the term variola, a composite designation such as *variola-alastrim* might be recommended. To my mind, this solution might satisfy their "unicism" and at the same time serve to distinguish a peculiar clinical and epidemiological form which can no longer be ignored.

II. Places of Origin and Geographical Distribution: Present Foci.

Africa.

The disease first appeared to the eyes of a pathologist as a distinct entity in South Africa. In 1904 De Korte gave its first description under the local name of *amaas* or *Kaffir-pox* at Graaf-Reinet in Cape Colony. It was by no means a new infection in the district, for in 1895 G. Turner had reported its existence (Mitchell) and Fehrsen has declared (1922) that so long ago as 1876 to 1878 he saw epidemics of it spread repeatedly, producing thousands of cases among the natives; he believes that the disease has existed among the Kaffirs since time immemorial. In 1910 Spencer and Grant affirmed the existence of amaas. This South African focus is still active (Mitchell, 1922) and it is not the only one in this quarter of the globe, for there have been epidemics since 1917 at Stanley Pool, at Leopoldville (von Hoff, 1923), and at Libreville (Gaboon) and Brazzaville in the French Congo (Lebeuf and Gambia, 1919). One naturally supposes that the disease has already reached still other regions of the African continent.

Central America and West Indies.

The focus in the West Indies and in Central America, the Antilles focus, has probably as long a history as that in the Cape. The first island on which para-variola was recorded was Jamaica, where so far back as 1867 Izett Anderson published his study of the epidemic of 1865 and 1866; he described it under the apt title of varioloid-varicella in order to express its hybrid nature among the eruptive fevers. De Korte quotes his description and uses it as a confirmation of his own ideas as to the epidemic specificity of the disease. In Cuba a similar infection was prevalent during the Spanish-American War, which under the name of *Cuba-itch* has invaded the Southern States extending even as far as Canada. In 1902–04 it was present in epidemic form in Trinidad, where it was noted by Bridger (1903), Dickson and Lassalle (1903), and Seheult (1908).

Since the year 1920 the West Indian focus has greatly increased in activity. In 1920–21 the epidemic involved in Jamaica 6000 persons (Moody, 1922), while Gideon (1920) estimates it at 9000 cases within six months. This Jamaican alastrim has proved a fruitful field for epidemiological observations by both English and American workers, and its virus has been employed for experimental work by Hector Read and Leake and Force (1921). The disease has been prevalent also in Trinidad (Dickson, 1923), in Hayti (Melhorn, Brown, 1921; Loughnan, 1923), and in San Domingo, from which it was carried by passengers to Antigua (Hill, Branch, and McDonald, 1923) as well as to Snake Island (Jones, 1922). An epidemic of "mild small-pox" was recorded in Cuba in 1921–23 (Hoffman, 1923). In their turn came the French Antilles, Guadeloupe, and Martinique, where last year there occurred the fierce epidemic described by Mr. Gouzien; in this epidemic all the hospitals were full to overflowing and recourse had to be made to temporary shelters to house the successive waves of cases. Arnould (1923) has given an excellent review of this outbreak in which he estimates the cases in Martinique at 4000; Baujeau (1923) has applied to it systematic observations and experiments on laboratory control.

In November, 1923, the s.s. *Oyapoc* carried the disease to the mainland through Cayenne in French Guiana (Chauvet). It is safe to say that the entire archipelago in the Caribbean Sea is infected to a greater or less degree and, with this as a focus, the disease has spread to the mainlands adjoining—i.e., to Guiana, to the United States, and to Canada, where it is prevalent but is simply labelled "small-pox." Our colleague, Mr. Chagas, tells us that during a tour which he made recently in the U.S.A., he found series of alastrim cases at Rolley in South Carolina, at Richmond, Va., and at Toronto. At the moment sparks from the blaze are falling on Europe and, as we shall see, a bombardment of the coast of Europe is going on with the alastrim virus of the West Indies and particularly of Martinique, where it is at the moment at the height of its epidemiogenic capacity.

Brazil.

We now come to the Brazilian focus. This was discovered and studied at Sao Paulo in 1910 by Ribas and other Brazilian doctors. The first cases were among country labourers ("sertanejos") travelling to work on the coffee plantations. They declared that in the interior of the State of Bahia the disease was extremely prevalent without ever being fatal; because of its rapid spread it was known colloquially as "alastrim." These labourers thus may be said to have identified the disease and made it known to the doctors. Spreading in this manner along the river San Francisco, the disease invaded different districts in the State of Sao Paulo and in the contiguous States of Minas and Parana so that, either in this way or by extension from the hinterland ("sertao") of Bahia, it reached Matto-Grosso, Goyaz, Minas, and the Southern States of Brazil. Beaurepaire-Aragao in the following year estimated the alastrim cases at 250,000; this is the highest figure known. Mr. Chagas found one of the earliest cases which occurred along the San Francisco in 1910, where he was studying malaria at the time; it was a case of a labourer coming from the "sertao" of Bahia whom he himself had vaccinated a few months before. Despite rigorous isolation of this man an intense outbreak occurred among the other workmen engaged in railway construction and among the local population. Mr. Chagas reports that nowadays there are merely small exacerbations here and there.

Australasia.

Para-variola has established itself also in Australia where it was reported at Sydney in 1913; Robertson has given a very complete account of this outbreak, containing a preface by Dr. Cumpston and some beautiful photographs. In this outbreak 1037 cases were sent to hospital; later a total of 2000 cases was reached with only three fatal cases among the lot. New Zealand was also affected and, in fact, it was his experience of the disease in New Zealand that enabled Lebeuf to identify it in the French Congo (Gouzien). In India cases of "mild small-pox" appear to have been recorded.

Europe.

Finally, Europe also has shared in the disease, a share which has not always been sufficiently recognised; the new eruptive fever has taken an endemic form in several different places, forming the *European foci.*

England.

England was the country in which the new invader first pitched its camp in the form of the tiny outbreak of 1919 when 31 cases occurred in a limited district in Norfolk and Suffolk. Copeman, who studied this, regarded the cases as similar in kind to Brazilian alastrim and the attenuated small-pox which he had seen at Trinidad in 1902; he had already seen similar cases in Cambridge in 1903. This new series of cases was due to importation from the Eastern Mediterranean by a sailor who had been there on a mine-layer during the war. There followed two small explosions in 1922, at Ilkeston (104 cases) and Heanor (55 cases), and then in 1923 the Gloucester outbreak in which 498 cases were sent to hospital. A complete account of the latter with descriptions and statistics has been given by Jameson and Painton. The extent to which England has now been invaded by what is called "mild small-pox" has been shown to us by Sir George Buchanan in striking fashion by means of the statistics and graphic representations of the ncidence and mortality of small-pox in England and Wales. The figures of cases increased from 336 in 1921 to 973 in 1922, and to 2504 in 1923. Yet the total deaths only numbered seven. England is now affected by an epidemic of *small-pox* which is widely diffused, but of a severity which is feeble or insignificant.

Switzerland.

As regards Switzerland we owe our information to Mr. Carrière. In the spring of 1921 a variety of small-pox presenting unusual features was noted in the canton of Zürich and later in that of Glaris from which it spread throughout a large part of Switzerland. After some doubts and discussions it was recognised as of the nature of variola and was called "*white-pox.*" In three years there have been notified 3900 cases with only three deaths.

France.

In France there have been isolated cases occurring in the Western ports which traffic with the French colonies in Central America; these have been mostly in coloured people recently arrived, especially from Martinique (Léon Bernard, 1923). A case in a passenger landing at St. Nazaire rom Martinique has just been found in Paris (Cambessedès, 1924). There is going on, thus, at the present moment, an active importation of the alastrim seed which may sprout eventually into an epidemic.

The Azores.

This has actually occurred in the Portuguese island of San Miguel in the Azores where small-pox is not endemic. On June 7th, 1923, the French ship *Vanquelin* arrived at Ponta Delgada from Pointe à Pitre (Guadeloupe) in order to disembark a negro who had fallen ill on board. The case was diagnosed as small-pox and in spite of the precautions taken (isolation and disinfection) alastrim spread rapidly, at first in the town, later throughout the island; it has displayed great power of spreading but has been extremely benign. Up to the month of April last 15,000 cases with only ten deaths have occurred in a population of 126,000 nhabitants (Jaime Neto); the case-incidence is thus more than 10 per cent. At present there are only sporadic cases n certain parishes. But the alastrim has not remained confined to San Miguel; in February last it invaded the sland of Terceira, having been brought by a person from Ponta Delgada who settled down near Angra. Here also, n spite of the precautions taken when the first focus was recognised, the epidemic spread throughout the whole sland. There have been no deaths and the epidemic was already on the down grade in September. A few days before I left Lisbon I saw a typical case of alastrim from the island of Terceira in the isolation hospital there.

Ubiquitous Distribution.

There are thus at present the following foci: the African, he Brazilian, the Caribbean, the American, the Australian, and, in Europe, the English, the Swiss, and that in the Azores. One is entitled to assume that para-variola exists lsewhere as well, occurring in the form of doubtful sporadic ases or epidemics of little gravity and being lumped together as "small-pox" or "varioloid" or "benign small-pox." t must be admitted that occasionally the last diagnosis has been the result of an official direction, diagnosis made by decree!

Supposed Racial Proclivities.

This summary of medical geography shows the strong endency of the infection to become ubiquitous and pandemic. t is decidedly no longer a simple nosological curiosity to be catalogued among those of secondary importance in an ndex of colonial or tropical diseases. The old conception of two different nosologies, the European and the exotic, has long ceased to have any justification if it ever had any xcept as a reflection of the traditional attitude of superiority f Europe over the rest of the world. This is proved once again by alastrim, which used to be considered as an endemic disease of the colonies in Africa and America only, but has now become a disease of Europe. The idea of its "colonial" nature has been pushed so far as the supposition that the white race was naturally immune to para-variola. Fehrsen in Africa actually held that the infection was confined to the Kaffirs since he had never seen a case in a white man. The same was thought to be true in Martinique, as Mr. Gouzien has told us, but latterly a few white people have also contracted the disease. In Brazil, moreover, alastrim had already attacked the mixed races of the interior. Yet, in France especially, the disease still continued to be regarded as the exclusive privilege of the black races (cf., the séance of the Academy of Medicine of October, 1923). This theory of the immunity of the white race, already impossible to maintain in view of the similar epidemics in the U.S.A. and Australia, has been completely exploded by the events at Ponta Delgada as I pointed out at the May session of the Office International. In this case there can be no doubt as to the nature of the disease: it was plainly an epidemic among people of pure white race infected by a negro from Pointe à Pitre; the direct carriage of alastrim from America to Europe had been detected in the very act.

Transmission from Country to Country.

These examples of this transport of the virus from one epidemic area to another are not numerous, and, in fact, I think the one just mentioned is the only instance of its carriage over a long distance. The trajectory, as it were, and the circulating routes of alastrim are still obscure. In Africa it appears in the hinterland of Cape Colony. Is this the primary focus and true origin of the disease? It is impossible to give a confident affirmative. In Brazil, again, it is in the back country, the "sertao," that the infection appears to hatch. In the Caribbean area Jamaica was the first island in which it was observed, and it is known that it infected the other islands later; now and then one seems to detect the passage from one to another. The Australian epidemic was said to have been linked with the outbreaks in the United States which were going on at the time in Chicago and Ontario (Robertson). In England the question of importation was mentioned only in the case of the Suffolk outbreak where a Mediterranean origin was suspected although no alastrim was known to be prevalent there. In Switzerland the invasion seems to have occurred without any evidence of para-variola in the surrounding countries, though these form naturally the only means of connexion with infected ports. The islands of San Miguel and Terceira in the Azores remain the only example where both origin and route of the epidemic are well established. From these islands the infection spread like oil on water throughout the Azores, which in this respect form a counterpart to the Caribbean Archipelago on the other side of the Atlantic.

III. Clinical and Epidemiological Characteristics.

In dealing with such a controversial subject it is necessary to proceed with caution if we would avoid hampering ourselves with prejudices. We ought more than ever to cling to facts, those which are obvious to everyone, but which are sometimes twisted and interpreted, for the purpose of dialectic, so as to support some preconceived theory. In this way a clear vision of things is obscured, some being given undue importance, and others made of little account, according to the necessities of the argument in favour of the cause which is championed. But while these partisan excesses should be avoided, we must also be on our guard against the excess in the opposite direction which is committed by those whom I may call the "agnostics," people who, being of opinion that the time is not yet ripe, are unwilling to commit themselves to anything, and are content to shelve the matter with a shrug of the shoulders. But as material for observation has accumulated for 20 years, it is now possible to draw some conclusions resting on more or less solid foundations, tenable until the contrary is proved. One may attempt these conclusions while realising that they will not settle the essential nature of the disease, and that in spite of the advances which are being made, we must still frequently be confronted by the insoluble.

Identity of these Para-variolas.

The first proposition to consider is one which few would find it possible to contest—namely, the clinical and epidemiological identity of these para-variolas which have appeared at different times and in different places, and have received various labels. The "amaas" of South Africa, the "alastrim" of Brazil, the "varioloid-varicella" of the Antilles, the "mild small-pox" of England, the "white-pox" of Switzerland—all these are only one and the same thing.

When Korte, in 1904, described the amaas of the Cape, he was struck by the points of resemblance to the epidemic of varioloid-varicella observed in 1867 by Izzet Anderson in

Jamaica. When, in 1910, Ribas found the alastrim of San Paulo, he connected it at once with the amaas of the Kaffirs. Armstrong compares the Sydney epidemic with the descriptions given by Ribas. When we examine the reports of the epidemics in Suffolk and Gloucester, we see the same symptomatic thread running through them. When Sir George Buchanan sent me information and documents relating to the English "mild small-pox" he said: "If you will look, for example, at the history of the outbreak in the city of Gloucester regarding their epidemic in 1923, you will find much which is similar to Dr. Copeman's descriptions, and I may say that I am disposed to think that the 'mild small-pox' described in Gloucester, like the mild small-pox in other parts of England which I mentioned to the Office International and also Dr. Copeman's cases in 1919–20, are all much of the same kind. If we apply the term 'alastrim' to any of them, we should probably have to apply it to all and to say that our present outbreaks are almost entirely 'alastrim.'" It is right to add that Sir George Buchanan was of opinion that the innovation which would be introduced by the adoption of this name would have no nosological value, but that is beside the present question. The "white-pox" of Glarus, Zurich, and other cantons would fit into the same picture, and so would the recent outbreak in the Azores. At first I had some doubts about the English and Swiss "small-pox," following the discussion which took place at the session of April–May last of the Committee of the Office International. After reading the report on the Gloucester outbreak, and the lecture on the Swiss epidemic given by Mr. Carrière to the participants in the exchange of sanitary personnel, no further doubt remains in my mind. To sum up, in Africa, in America, in Australasia, and in Europe, everywhere and for half a century, whether in coloured or white races, alastrim has presented a uniform "facies," a syndromal physiognomy whose essential features have been the same. This proposition seems to me one of great importance which deserves to be kept in mind. It is necessary to consider the characteristics of this epidemic disease type. But before doing so I may give the following notes on the outbreak at San Miguel.

Summary of San Miguel Outbreak.

The report of the health delegate at Ponta-Delgada (Jaime Neto) is interesting, because it simply describes facts which were new to the author, and it is not influenced by any special preliminary study of the disease. The delegate recognised from the outset that the disease in question was not pure variola. The symptoms were: slight fever, rarely reaching 39° C., lasting two or three days; slight headache, pain in the back, occasionally vomiting, and furred tongue; the patient then remains afebrile and the eruption follows, papules at first, quickly changing to vesiculo-pustules, some containing clear and others a milky fluid; later on pustules are formed. The eruption is fairly general and a few umbilicated lesions are found; it is rarely confluent. Its development takes 24–48 hours; some days later desiccation commences and proceeds rapidly, leaving only a purplish discoloration which gradually fades to white. The size of the lesions varies from that of a grain of corn to that of a pea. As a general rule, the rash begins on the face, spreads more or less over the whole body, especially the face, hands, and feet. The general condition remains excellent, and in a few days the patient is free from any discomfort.

With regard to the origin and course of the epidemic, it appears that a French boat, the *Vauquelan*, coming from Point à Pitre, arrived at the port of Ponta-Delgada on June 7th, 1923. A request was made that a sick man, a negro, might be disembarked. The maritime health officer diagnosed the case as small-pox, and the patient was admitted to the isolation hospital. On June 17th an attendant, who had been in contact with the patient's wearing apparel, was attacked with a fever, and later with a rash, which was diagnosed as chicken-pox. The health delegate inquired into the case on the 21st, and an investigation showed that a "foyer" of infection had already been formed. Three brothers of the attendant were among those infected. The epidemic spread in spite of the measures taken.

A vaccination service was organised, and it was found that the persons vaccinated were not attacked, or if they were, that the attack was slighter than in the case of non-vaccinated persons. If the vaccination is performed just before the eruption it rarely takes, and if performed during the eruption or after desiccation it never takes.

Our health officer came to the judicious conclusion that what he saw was too much for chicken-pox and too little for small-pox. I was about to write to him to inquire into the exact nature of the epidemic when I received a fresh letter; he himself had already made the diagnosis of alastrim after reading what was said in the Bulletin of Office International. The picture of the outbreak which took place at Terceira in January of this year is exactly similar. Other information on the epidemic in the Azores is given elsewhere in this paper.

THE EPIDEMIC DISEASE-TYPE OF ALASTRIM.

The description of alastrim should be undertaken by bringing it into contrast with the two analogous diseases—chicken-pox and small-pox. Its resemblance to each is so striking that the term *variolo-varicella* has been used to signify its hybrid symptomatology. This resemblance has been the cause of clinical confusion among practitioners whom the disease has taken unawares, particularly at the onset of an epidemic; some thinking the case to be small-pox, others chicken-pox. This happened at first at Ponta-Delgada, as it has elsewhere.

One can say, however, that nowadays the resemblance of alastrim to chicken-pox causes no embarrassment. Although diagnostic errors are always possible, the two diseases are fundamentally distinct, for chicken-pox has possessed, for a long time past, its own pathological characteristics, or, in other words, it is a specific manifestation of a polymorphic virus, the various other specific effects of which, according to the pathological concord associated with the name of Mr. Netter, include zona or herpes. The same, however, cannot be said of small-pox. Some associate alastrim with it, others differentiate. In comparing the two, it would be well here to set aside theoretical aspects, otherwise important, and to consider only the material, nosographical, side to see if a satisfactory basis exists on which to determine similarities and differences.

In contrasting these two morbid entities, the new and the old, it would seem that there ought at least to be no doubt or dispute about the nature of the latter, which has been known to doctors, and no less to the public, for so many centuries. Not so, however, in fact. Experienced practitioners only acquainted with the old-fashioned severe small-pox fall under suspicion as likely to fail to appreciate that a disease once so formidable may have become attenuated by time. Personally, however, though I am among the older practitioners, I may be acquitted of the charge of closing my ears to the pundits of epidemiology.

A type must be chosen for comparison, and it should be one upon which everyone is agreed. This will, no doubt, be the classic type of small-pox—the *variola vera*—the variola of Sydenham. It is not necessary to go back to the seventeenth century to recognise Sydenham's small-pox. It is still with us, even in countries such as England and Switzerland where small-pox was almost becoming extinguished until their compulsory vaccination laws received a check.

For example, Sir George Buchanan has told us of the epidemic in Glasgow in 1920–21, an epidemic of the true complete type of small-pox, with its customary severity, which broke out two years before the "mild small-pox" in Gloucester. And Mr. Carrière has also reminded us that the small-pox in Zurich and Glaris had been preceded by ordinary small-pox, of habitual severity, in Bâle. That is to say, ordinary small-pox remains in the very regions where the eruptive fever which we are discussing has arisen, and it can be used for the purpose of comparison. Thirty years ago, when I was medical officer of health in Oporto, we had several years' experience of widespread and severe epidemics. We can refer present occurrences to the memories of that period which remain to us.

If we have just spoken of Sydenham's variola as a kind of standard, we do not wish to infer that it is to be strictly confined to the type which is described in the pages of the great epidemiologist. One knows how relatively frequent, right up to the first decades of the nineteenth century, was the redoubtable confluent form, nearly always fatal. But it is now less frequent. The diminution may be attributed to the influence of vaccination, although it is observed also among the unvaccinated small-pox cases. Similarly small-pox epidemics reveal variations in type and severity—as in the time of Sydenham, who speaks of *varioles mitiores*. But these considerations are not inconsistent with the existence of a disease-type, common to all these epidemics, which assures the perpetuation of the particular nosological character of small-pox. It is to this, what one may call the normal small-pox of every-day occurrence, that one must refer the characteristics of alastrim.

The Rash.

A "pre-eruptive" rash is very rare in alastrim; not more than two or three cases are found even in the big epidemics. A rash on the mucous membranes is less rare. The rash must be considered in relation to its distribution and its character.

Distribution.—The rash generally appears on the third day; first on the face and neck, progressing to the trunk, then the arms and legs. Sometimes, though seldom, it commences on the limbs. The efflorescences appear at the same time, without repetition or subsequent additions in the same region of the body—unlike varicella in which distinct cropping occurs. Frequently, in a third or more of the cases, they are fairly profuse. At Ponta-Delgada numerous cases were noted with a generalised eruption scattered all over the body. Generally rare on the trunk, the number increases towards the extremities, the head, the hands, and the feet. The rash has the centrifugal distribution (Painton), usual in small-pox and contrary to that found in chicken-pox which is centripetal—i.e., abundant on the trunk and decreasing towards the extremities. Chauvet, in cases which he has studied, believes that he has seen rashes with a nerve or even a definite nerve-root distribution.

Character.—The eruptions pass successively through the well-known stages of macule to papule, papule to vesicle, and vesicle to pustule. It is incorrect to state that the eruption may be vesiculo-pustular from the outset: this is contrary, in particular, to the observations of Ribas and Baujean. The cycle is completed more rapidly than in small-pox; the vesicle grows more quickly, at times with opalescent contents, which has given rise to the name milk-pox. Aborting of the rash, wholly or partially, is common.

So far the difference from small-pox is not very noteworthy. A clear distinction is, however, made by the shape of the vesicle which, in growing, becomes round and convex like a bulla, and domed as in chicken-pox. In small-pox, on the other hand, the vesicle remains flat or even depressed in the centre. The chicken pock and the alastrim pock are unilocular, the small-pock is septate and multilocular, the partitions causing the depression in the centre—the phenomenon of umbilication. Neither the vesicle nor pustule of alastrim are umbilicated; there is no primary or secondary umbilication. This is said by some observers to be due to the fact that the lesion is more superficial. Desiccation completed, the crust falls off leaving a mark on the skin which remains for some time, but without cutaneous erosion and without a permanent scar. *Alastrim leaves no pitting on the face.* These signs, being of major importance, deserve consideration.

But Wanklyn, Mitchell, Baujean, and others have stated and demonstrated that the well-known diagnostic signs of vesicular eruptions, classified according to the configuration of the pock, are liable to cause error. In small-pox one may observe round vesicles and pustules, just as in alastrim one may find umbilication; and, finally, small-pox may occur without cicatrisation while alastrim may leave marks on the face.

Quite recently, in Martinique, vesicles were noticed which were flat, sometimes on the limbs, and it is also stated that patients have been permanently marked (Baujean). Mitchell says that he has found several umbilicated spots on Europeans with alastrim; this was of less frequent occurrence in negroes, perhaps because of differences in the structure of the skin. In the Lisbon case several pustules, depressed in the centre, were observed on the arms and legs: but this was merely the effect of desiccation; false umbilication was also noted by Arnould in Martinique, and was attributed by him to the emptying of the pustule. When they were compared with the pustules of another patient in hospital with undoubted small-pox, it was evident that those of the latter case were uniformly and deeply umbilicated; the distinction was well marked.

However this may be, these facts should be taken into account at the bedside so as to avoid making hasty and dogmatic diagnosis, based solely on the character of the eruption which must not be set up as pathognomonic. The important matter for the epidemiologist, however, is the *generic* character of any given clinical characteristic during an epidemic; exceptions do not invalidate the rule; on the contrary, they confirm it.

Briefly, in epidemics of ordinary small-pox, umbilication and scars are the rule, and correspondingly their absence is the rule in alastrim. I think that this proposition can hardly be any longer contested. The fusion of contiguous pocks which may occur either in the vesicular stage (more correctly known as primary confluence) or in the pustular stage (coherence or secondary confluence) is comparatively frequent in alastrim which is accompanied by a profuse rash. Every observer speaks of this, and so it was at Ponta-Delgada. Baujean records "in some cases of partially confluent eruption, the vesicles, mingling into large blebs, became, in the suppurative stage, veritable small pockets of pus raising up the skin in certain parts of the body, particularly the limbs." Ribas has noted the absence of the characteristic odour emanating from variolous patients during the suppurating and crusting stages; but alastrim in the confluent and cohesive varieties can also give off a most nauseous smell. (Baujean, in Martinique, Van Roof, in Leopoldville.) Cohesion and confluence are characteristics common to small-pox and alastrim, while at the same time they form a contrast, for, as we shall see, their prognostic significance differs widely for each.

Eye complications are very rare; at San Miguel, however, a few cases of keratitis were observed, three of them followed by loss of the eyeball (communication of Jaime Neto).

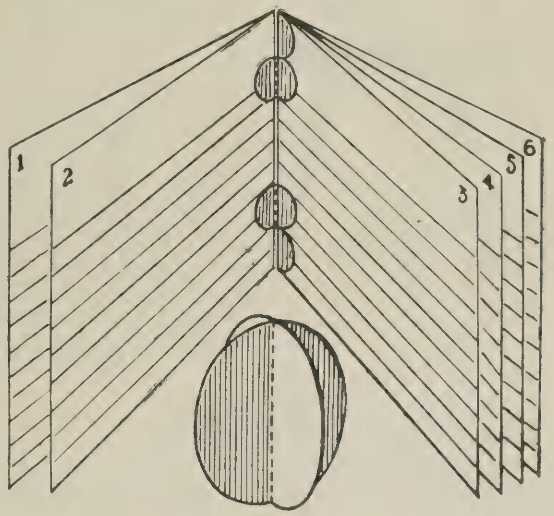
(*To be concluded.*)

INCRUSTED WATER MAINS.

THE Bradford water department has adopted with success a new method of improving the water-supply through its mains. In these mains, which are from 30 to 35 inches in diameter, it was found that during the course of half a century the interior of the tubes had become incrusted with a deposit from the water, and which the pressure and onward flow of the water was unable to remove. A special scraping apparatus provided with revolving blades and stiff brushes was inserted into the main at one of the hatch holes or at an opening made on purpose, and was forced on by the water pressure and removed at the next hatch hole. The machine was driven by the water pressure and in revolving it dislodged the incrustation. The main was cut at intervals of a quarter of a mile apart, and in some portions of the main the scraper in its onward course discharged about seven tons of incrusting material. The mains were restored to a state of efficiency equal to that of the original main, and it is calculated that by obviating the necessity of laying new pipes a sum of £65,000 has been saved.

A HANDY CARD INDEX CLIP.

ALL who use a card indexing system know the practical difficulty of keeping a series of cards together by means of the ordinary wire clip. This difficulty may be obviated by a simple and ingenious contrivance submitted to us by Mr. J. M. F. Whitby, a medical student in his final year. Circular pieces of transparent linen, measuring 0·7 inches in diameter, are sewn together across a diameter to make a little book of four semicircular leaves. Two pairs of adjacent surfaces are covered with an adhesive substance for the purpose of holding the edges of cards placed between them. The M.H.S. (i.e., Medical History Sheet) clip, as it is called, is thus a strong, transparent linen hinge by which any number of cards can be attached together in book form. The hinges are practically untearable. The device is already in use for case-sheets at a hospital and by a number of insurance practitioners to whom as a body it should specially appeal. The price of the clips is 1*s.* 3*d.* per 100 or 5*s.* 9*d.* for 500, and they may be obtained from Messrs. Bridge and Co., 92, Chancery-lane, London.



HERBALIST PRACTISING AS A DOCTOR.

OUR South African correspondent writes: An intelligent-looking Hindu was recently fined £15, with the alternative of three months' hard labour, at the Durban District Court, on the charge of practising as a doctor without a licence, and with false pretences. The accused had visited several patients, on whom he practised palm-reading and other "sorceries." He was known among the Indian community as a herbalist, and many people believed in his ministrations. Four specific acts of doctoring were alleged, and for these the accused had received £7 3*s.* 6*d.* The productions in the case were a small phial of yellow sulphurous liquid, a small curry tin containing stones embedded in a pink powder, and a small packet of beans. The medicine in the phial was supposed to be a panacea for all ills, and the accused had asked £4 for it. The magistrate said that he could come to no other conclusion than that the accused held himself out to be a doctor, and had deluded credulous people into believing him.

AN ART CALENDAR.

THE Clayton Aniline Company, Ltd., of Upper Thames-street, London, E.C. 4, have issued an art calendar which takes the form of a reproduction of *The Doctor Forbids*, a picture by the late Edgar Bundy, A.R.A., which attracted attention at the Royal Academy in 1916. The picture represents presumably a doctor and his friend or patient dining together, the former forbidding his companion to take the wine which the butler is about to offer him. The warning gesture of the doctor and the surprise in the face of the seemingly robust and healthy diner are well depicted, and the hesitating and puzzled attitude of the butler is also closely observed. The issue of a calendar at Christmas-time with such a message as its conspicuous frontispiece shows how far we have travelled recently, as a nation, on the road to temperance.

A USEFUL FOLDING CHAIR, "THE STAKMORE."

FOLDING chairs have many advantages, but they are frequently cumbersome, difficult to manipulate, and liable to catch the clothes of the sitter. These disadvantages are, however, absent in the chair here illustrated. Made of bentwood, in mahogany and oak colours, with upholstered seats, the chairs are perfectly stable and can be folded flat in a few seconds, while it is extremely unlikely that even flowing drapery will be caught in the moving joints of the seats. The chairs are particularly suitable for hospitals, nursing homes, and such like institutions, or, indeed, anywhere where space is of importance, as they can be folded flat when not in use and stacked in a pile of negligible height—six chairs make a stack only 8 inches high. The chairs, which are made in England, are sold at 17*s.* 6*d.* each by Messrs. Rees, Mace and Co., 121, Cannon-street, London, E.C. 4.

HEALTH CONDITIONS IN CYPRUS.

A REPORT for the year 1923 has recently been received at the Colonial Office and it gives the population as 322,000, of which number 61,422 are Mohammedans, the bulk of the remainder being Greek-Christians of the Autocephalous Church of Cyprus. Public health was again good, except for an epidemic of measles, which caused many deaths among children. The stringent quarantine measures which continued to be in force effectually prevented the introduction into the island of plague, typhus, and other virulent diseases prevalent in all the neighbouring countries of the Levant and the Near East. This complete immunity cannot but be regarded (says the report) as eloquently testifying to the efficacy of the medical services responsible when it is considered that several thousands of refugees, many of the poorest class, have been received in Cyprus during the past two years from Smyrna, Cilicia, and the coasts of Asia Minor generally. Only one case of small-pox occurred during the year, and over 19,000 vaccinations were carried out. The prevailing diseases were, as in previous years, those of the digestive and respiratory system, influenza, diseases of the skin, rheumatism, malaria, and enteric fever. The anti-malarial campaign was, as usual, conducted under the supervision of the medical officer of health, and the incidence of malaria was less heavy than in 1922. The spleen-rate for the towns as a whole showed a decrease. The total number of births registered during 1923 was 25·1 per 1000 of the population, as against 28·0 per 1000 in 1922. The deaths in the same period were 17·7 per 1000, as against 29·0 per 1000 in 1922. The death-rate amongst infants under one year of age was 149·7 per 1000, as compared with 167·7 per 1000 in the previous year. The year generally was more healthy and the climatic conditions not so exhausting as in 1922. There were Government maintained or aided hospitals in operation in the six principal towns, and 16 rural medical officers, each with his headquarters and a Government dispensary at a central station, worked among the village population. In addition there were eight branch dispensaries in operation. The hospital recently constructed at Limasol was opened in February and is now in full operation. Over 900 patients were admitted to the Central Hospital at Nicosia, which is fitted with 56 beds, and the out-patients numbered about 8200; 130 surgical operations were performed. More than 17,000 persons obtained relief at the rural dispensaries. At the close of the year 105 inmates were detained at the lunatic asylum. The number of lepers in the leper farm at the end of the year showed an increase to 75, as against 69 in 1922. There were 13 admissions to the farm, as compared with 5 in the previous year. This increase is largely attributable to the fact that patients are voluntarily presenting themselves for treatment in consequence of the excellent results that have been attained by the use of chaulmoogra oil and preparations of antimony. Leprosy in Cyprus is now well under control and hopes are entertained that it may be possible in time to entirely eradicate it from the island. The number of children at the close of the year in the home for the healthy children of lepers was 10, all of whom remained free from any sign of the disease. The climate of Cyprus is, generally speaking, temperate and healthy, though the excessive heat of the plains during the summer is trying to Europeans. The heat is, however, dry, except on the coast, while the winters are cold and invigorating. The absolute mean temperature for the year at Nicosia was 67° F., the mean maximum temperature 78·80°, and the mean minimum 55·20°. The highest shade temperature recorded was 106° and the lowest 34°, showing a range of 72°, the maximum and minimum recorded during the previous 15 years having been 110° and 26° respectively. The rainfall for the last 10 years has averaged 19·08 inches per annum. The experience of the last decade would seem to show that the climate tends slowly, but surely, to change. While the excessive heat in the plains continues to prevail during mid-summer, the winters are damper and colder, and late rains not infrequently fall, a circumstance attributable principally to the conservation and extension of the island's forests. Several earthquake shocks, the majority of a slight character, were felt at Limasol, particularly during the month of September, while one was also felt at Nicosia.

DONATIONS AND BEQUESTS.

Mrs. Jane Elizabeth Shaw, Sheffield, who left property of the value of £37,068, bequeathed £600 to the Sheffield Royal Hospital to endow a cot in the Children's Ward, and £1000 to the Salvation Army. After fulfilment of certain other bequests she left the residue of her property to the Sheffield Royal Hospital, the National Protestant Church League, the Sheffield Pawnbrokers' Pension Fund, the Sheffield Blind Institution, and the Jessop Hospital, Sheffield.—Mrs. Julia Grace Hulke, widow of John Whitaker Hulke, F.R.S., sometime President of the Royal College of Surgeons of England, left unsettled property valued £18,923, of which £18,171 is net personalty. The testatrix, after providing for bequests of about £8000, gave the residue of her property, and also that over which she had power of appointment under the trusts of her marriage settlement to the governors of Middlesex Hospital for their convalescent home at Clacton-on-Sea, on condition that it be called the Hulke Endowed Convalescent Home. If it be not so named, the residue is to go to the governors for founding and towards maintaining a home for incurables in connexion with the hospital, to be called the Hulke Home for Incurables.—Mr. Edward Philips Thomson, Whitchurch, formerly of Liverpool, left £1000 each to the Liverpool Royal Infirmary, the Royal Southern Hospital, the Children's Infirmary, Liverpool, and the Epileptic Hospital, Maghull; also £100 each to the Salop Infirmary and the Salop Eye and Ear Infirmary. He also left £2000 to Dr. Arthur M. Watkins, of Whitchurch, and £500 each to Dr. Peter Davidson, Liverpool, and Dr. Charles H. Shears, of Hydehill, Dartmouth.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE.

West London Hospital, Hammersmith, W.

MONDAY, Dec. 22nd.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Bishop Harman: Eye Dept.

TUESDAY.—11 A.M., Dr. McDougal: Electrical Dept. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Dr. Dowling: Skin Dept.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

An Address

ON

SOME PHENOMENA COUNTERFEITING ORGANIC HEART DISEASE.

Delivered before the Derby Medical Society

By CAREY F. COOMBS, M.D., F.R.C.P. Lond.,
PHYSICIAN (WITH CHARGE OF OUT-PATIENTS), BRISTOL GENERAL HOSPITAL.

In moments of depression I have been tempted to describe the work of a consulting physician as divisible into two parts: he is concerned either with breaking it to patients that there is nothing to be done for them, or with persuading them that there is nothing the matter with them. Even if the first category be more or less hypothetical, the second is actual, and if one's lot in life be cast among the cardiologists, a large part of it is devoted to such patients.

There are several reasons for this. In the first place, abnormal cardiac sensations carry with them an ominous flavour. A deep-rooted instinct tells the patient "Your heart is working wrongly." Then again, the public is convinced that heart disease means sudden death. Finally, certain of the symptoms and signs of cardiac disease have their imitators, and it is easy to fall into an error and to confirm in the patient's mind his direst fears, even when there is no real foundation for them. It is to some of these pitfalls that I wish to direct attention.

Perhaps we do not always realise how great an impression a diagnosis of heart disease makes on the patient. To many it is tantamount to sentence of death, and even if you should explain that there are forms of heart disease which are compatible with long and active life the patient is apt to discount your explanation on the ground that you only tell him this kind of story to let him down gently. Over the man who has been told that his heart is unsound a dark shadow hangs, a shadow that it is much easier to invoke than to dispel. Clearly, then, a diagnosis of cardiac disease is not to be made lightly or unadvisedly.

But it is not only the sin of commission of which we are guilty. Often a mere failure to say decisively to a patient "There is nothing wrong with your heart," is enough to leave him rooted in a conviction that something is wrong, and if the doctor, feeling himself on insecure ground and not sure about the absence or presence of a cardiac lesion, should allow himself to say something vague about a "weak heart," irremediable harm is done. We must, I think, school our minds to a certain decisiveness in this matter of diagnosing heart disease, and to an abhorrence of the practice of playing for safety at the expense of the patient's peace of mind. And one essential ingredient in this spirit of decisiveness is a confidence born of the knowledge that, though certain pitfalls have attended the path of diagnosis, those pitfalls have been foreseen and therefore avoided.

MISLEADING SYMPTOMS.

Fainting.—One misbelief that is commonly met among the laity is that fainting is a prominent symptom of cardiac disease. You will agree with me, I think, that apart from the very rare Adams-Stokes syndrome, in which syncopal or epileptiform attacks arise as a result of cardiac pauses and cerebral anæmia, fainting attacks are almost unknown as a feature of cardiac disease. Many of the persons who "faint" are in reality suffering from minor epilepsy, and you must all of you have been compelled to give this explanation to an anxious mother asking whether her child's heart is sound. Others, again, are suffering from a combination of circumstances which may induce such a pitch of cerebral anæmia as to cause a "faint"; a combination of slow pulse with low blood pressure. Most often it is seen in adolescents, especially in those with vagotonia—i.e., with a vagus which is over-effective as a break on the speed of the heart beat. Quite often, too, persons who have attacks of giddiness resulting from disease of the labyrinth miscall those attacks "fainting," and ask themselves whether they may not be the victims of heart disease.

Cardiac Pain, True and False.—"Pain over the heart" is also a symptom that causes much needless distress. Often it is flatulent dyspepsia; sometimes it is parietal pain; but if it is actually over the heart, or rather over that place where the "man in the street" believes his heart to be—somewhere below and to the outer side of the left nipple—it is almost certain that the pain is not cardiac. True cardiac pain is far more often mesial than lateral. Again, whereas the false cardiac pain often bears no definite relation to exercise, true cardiac pain can always be connected—at some time or other at least—with exertion. Moreover, there is a constrictive or oppressive character about most cardiac pains that is highly suggestive, and if this is wanting from the picture one should be chary of ascribing the pain to cardiac disease.

Palpitation is another sensation to which the mind of the patient attaches undue importance. By far the commonest cause of this symptom is tachycardia of the nervous type. In treating patients with this disorder—the civilian counterpart of the "D.A.H." syndrome with which the war and its aftermath have made us so familiar—I do not feel that our duty is quite at an end when we have assured them of the absence of organic disease. We are more likely to effect lasting good if we can tell the patient what is the cause of his symptoms. But even where the actual cause of this visceral neurosis cannot be found, much good is often done if one can, with a confidence that is visible in the expression of one's face and audible in the tone of one's voice, say that the heart is free from disease. This alone, by brushing away the fear of death that is implied in the layman's view of heart disease, may so far reduce his mental perturbations as to relieve him sensibly of his tachycardia.

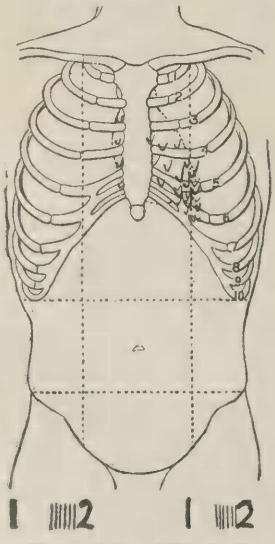
ARRHYTHMIAS.

But if we are to speak with confidence such as this, we must be sure of our facts. There are certain abnormalities that are of no importance, and it is our failure to discriminate between these and those that are of importance that leads to indecision and actual error. Let us first look at the various kinds of arrhythmia. I know we are told that if we are to decide with confidence whether the arrhythmia in a given case is important or not we must fortify ourselves with graphic records, gained by the use of the polygraph or the electrocardiograph. This is a counsel of perfection. Few have time or money enough to use these methods as a matter of routine, and it is clear that if a knowledge of the different kinds of arrhythmia is to become general—as it should—it must be by means less difficult to apply. My own belief is that in nearly all cases of arrhythmia it is possible, by feeling the pulse, watching the jugular vein, and listening to the heart's sounds (not necessarily all at once), to gain the requisite information, and on the basis of that information to separate the various types of irregularity from one another. Let us see whether this plan can be applied to those abnormalities of rhythm which may mislead the observer into a diagnosis of morbus cordis. Perhaps the commonest of these is the sinus arrhythmia of childhood and adolescence. Now, in the first place, it is well to recollect that a really regular pulse is almost unknown in children under 10. The heart beats irregularly at this age because the vago-sympathetic balance that determines the speed of the heart is so easily got at; it is affected by mere normal respiration, by the mildest of psychical influences, and reflexly by all sorts of afferent impulses. All these disturbances are continually plucking at the cardiac controls of the child and the adolescent, so that it is not to be wondered at that the rate of the heart should wobble a good deal at these ages, as indeed it does throughout life in many people. And when this wobbling is very pronounced, an irregularity in the pulse which may be mistaken for a sign of disease is the result. But if we watch it carefully we note that it is not an absolutely continuous arrhythmia; there are periods of regular beating from time to time. And the irregularity itself displays a kind of plan; the pulse speeds up and slows down in an orderly manner, and these changes in speed can often be traced to the effect of the respiratory act, so that the arrhythmia is clearly physiological and not pathological. Add to this the fact that the normal double flick can be seen in the jugular vein with each beat of the heart, and you have strong reasons for saying "The whole heart participates in this irregularity, which is therefore impressed on the heart from without and not caused by disease within the heart itself." That this supposition is true will be confirmed in almost every instance by an examination of the heart, which will show no signs of organic disease. Indeed, it would be a safe plan to ignore all arrhythmias in children and adolescents unaccompanied by other signs of cardiac disease. One of the most confusing points about this kind of irregularity is its almost invariable presence in children convalescent from an acute illness, but the rule enunciated above still holds good here; unless there are other symptoms and signs of cardiac disease, irregularity of the pulse in a child is physiological and of no diagnostic import.

THE PREMATURE BEAT.

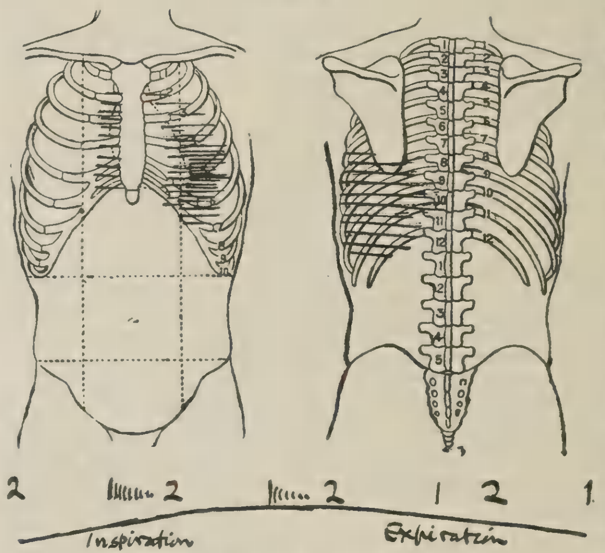
Another kind of irregularity which often makes a great impression on the mind of the patient is the premature beat. Nobody knows how and why such beats arise, but clinical experience proves that they may nearly always be ignored so far as prognosis is concerned, and that, as a rule, it is better not to attempt to treat them, as this only stamps on the patient's mind a belief in their significance. In elderly persons they are very often met with; in younger persons less often, and in both they may or may not coincide with signs of cardiac disease. In the absence of other signs of cardiac disease the patient should be encouraged to ignore them; and even when they occur in persons with cardiac disease they add nothing to the gravity of the prognosis. It is important to be confident of this, for patients are greatly troubled by them. They describe their sensations in various ways. Some are impressed by the feeble beat, the sense of cardiac pause; others by the big thumping beat that follows after the pause. They get into the habit of waiting for these sensations, and from this they pass to a constant feeling of pulses and counting of beats, and so to a distressing kind of hypochondriasis, which is aggravated if the doctor lets himself appear in the least impressed by the alteration of rhythm. The arrhythmia is of a kind so easy to recognise that there is no room for uncertainty about it. The finger on the pulse detects pauses between the normal beats; sometimes the little premature beat that is responsible for the pauses between the full beats is too small to be felt at the wrist, sometimes it is clearly perceptible. When it is perceptible, it is recognised as a little kick that the pulse gives at a short interval—an abnormally short interval—after a normal beat. The heart sounds that accompany this little beat are also heard to follow, at a very short interval, those of the last normal cycle; and they are often very subdued sounds, barely audible, as if they repeated in a hurried whisper the sounds that the last full heart-beat had just spoken aloud. Often these premature beats occur regularly after every second, third, or fourth beat; even so, it should be noted that the "dominant rhythm"—the regular rhythm of the heart—remains. This is an irregularity that is only occasional, not complete or perpetual. This kind of irregularity—the premature beat or extrasystole—is also apt to cause a good deal of needless alarm when it presents itself in the shape of a missing of beats. The patient who feels his own pulse and finds that it drops beats from time to time is apt to fear all sorts of evil. Yet, nine times out of ten, the "dropped" beat is not really dropped. The gap is due to a premature heart-beat (too small to send a wave to the wrist) with the pause that follows it. That this is so can practically always be proved by listening to the heart sounds and feeling the pulse at the wrist at the same time. The gaps in the latter will be found to coincide with premature beats, just audible at the apex of the heart. If there is any doubt as to these facts, it is well to check them by graphic methods, and one is then in a position to say to the patient, with the necessary confidence, that the irregularity is of no consequence. (Fig. 1.)

FIG. 1.



F., aged 55. Occasional premature beats.

FIG. 2.



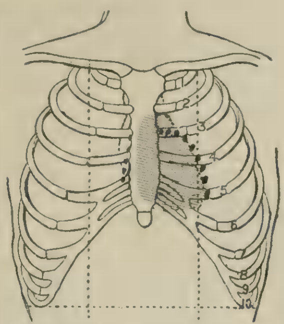
Cardio-respiratory murmur.

THE MEANING OF MURMURS.

Mistakes in cardiac diagnosis are, like all other mistakes, from that of our first parents onwards, a series of downward steps. The first step is made by the patient, who attaches undue importance to some abnormal cardiac sensation. The responsibility for the next is, perhaps, shared by patient and doctor; some departure from the natural rhythm is detected, and the doctor's confidence in the patient's health—already shaken by a history impregnated with the air of tragedy—is still further undermined. But for the last step of all, which causes words to be spoken that can never be unsaid, the doctor is often solely responsible; and that last step is the discovery, or rather the misreading, of a murmur. This is the "facilis descensus" that leads so many innocent victims into the slough of invalidism; and often the final irrecoverable plunge is precipitated by this unhappy propensity of ours to be stricken with panic in the presence of a murmur. If we had been taught, more emphatically than most of us were, that of the murmurs heard over the heart a minority only are due to cardiac disease, it would perhaps have engendered in us a more cautious attitude towards murmurs in general. What we ought to do is to say to ourselves, "What is the cause of this murmur?" before jumping hastily to the conclusion that the cause must necessarily lie within the heart. The need for these reflections will be best illustrated, perhaps, by a consideration of those murmurs which most often lead to error—namely, systolic murmurs in the region of the maximum heart-beat.

Cardio-respiratory Murmurs.—I suppose the commonest kind of systolic murmur heard over the apex-beat of the heart is that which is variously described as cardio-pulmonary or cardio-respiratory. If you are on the look-out for this it is astonishing how often you come across it. The characteristic facts about it are its blowing or whiffing character, its very obvious increase in intensity during or at the end of inspiration, with a corresponding tendency to disappear during expiration, and its liability to disappear altogether, or, at all events, diminish in intensity when the patient lies down. Often it is heard along both the right and the left borders of the heart and below the angle of the left scapula behind. It is most readily detected when the pulse is quick, as, for instance, during nervous excitement or in pulmonary tuberculosis. Most probably it is a kind of pleuro-pericardial friction. What we are concerned with here is to recollect that so far as the state of the heart is concerned it has no significance whatever. (Fig. 2.)

FIG. 3.



General systolic murmur. Boy, aged 9. Fever 100–102° F. for 14 days. Abdominal pain.

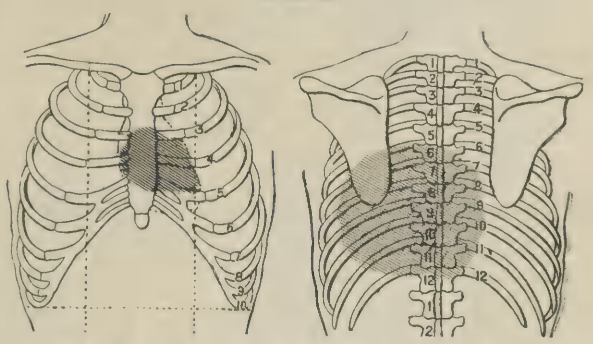
There is a tradition that if a systolic murmur heard at the mitral area is also audible below the angle of the left scapula, it is organic in origin. This is not true. The cardio-respiratory murmur is also heard very often in this area. In fact, I should be tempted to say that the fact that a murmur is heard at this spot is evidence against rather than for its organic origin.

Exocardial Squeaks.—There is another class of abnormal sounds not very different from the cardio-respiratory murmur in that they also vary widely with posture and respiration, and are also due to some abnormality outside the heart. These sounds are harsh squeaks, heard for the most part at or internal to the maximum impulse, and varying with extraordinary suddenness according to the conditions under which the patient is being examined. Both these kinds of abnormal sounds, being exocardial in origin, have nothing to do with cardiac disease, and should simply be ignored.

Hæmic Murmurs.—A third imitation of mitral disease is sometimes afforded by those murmurs which are grouped together under the name "hæmic." A recent example of this was seen in a boy of 9 who had continued fever, and of whom it was feared that he might be developing a cardiac lesion. But it proved on examination that his systolic murmur was heard with equal intensity at all parts of the præcordium, and we argued that as this murmur was so general in distribution it must be due to some cause which also was generally distributed; that is, to the toxæmia, probably tuberculous, which was also responsible for his fever. (Fig. 3.)

The Murmur of Patent Interventricular Septum.—One other kind of murmur that is sometimes mistaken for that of mitral incompetence is that systolic murmur which is heard with greatest intensity, not at the point of maximum impulse, but rather at the inner end of the fourth left interspace. In a number of individuals I believe that this murmur is due to a patency of the interventricular septum. In such cases the murmur is loud at its point of maximum intensity, but if you follow it away from that area in either direction, you pass suddenly to a point at which it is inaudible. If it should be accompanied by symptoms or signs of other congenital defect diagnosis is easy; but what I am more particularly thinking of is the class of case in which this murmur is the only evidence of anything abnormal, and what I am constrained to suggest at this point is that we must be careful not to be led astray into a diagnosis of acquired cardiac disease by the unsupported testimony of such a sound as this. (Fig. 4.)

FIG. 4.



Central systolic murmur. Probably due to congenital imperfection of septum ventriculorum.

Now what is true of systolic murmurs at the apex is also true, though to a less extent, of other murmurs. One or two examples of these may be alluded to before we come to general principles.

Presystolic Murmurs.—First, there is the imitation presystolic murmur sometimes heard over the impulse of the perfectly healthy heart when it is beating fast. To remember the possibility of such a thing is enough to enable one to avoid this mistake, particularly if it leads to an examination with the patient lying down. If it is a true presystolic murmur this will make it louder, if it is only a false one it will probably disappear.

Pulmonary Murmurs.—Systolic murmurs at the pulmonary area may cause difficulty in diagnosis, particularly during childhood, when there is a very natural tendency to ascribe them to congenital malformation. Sometimes, however, one comes across a murmur of this kind which is quite loud within a narrow circumscribed area and not to be heard in the back, or even as near to the area as just below the clavicle. These systolic murmurs localised to the immediate neighbourhood of the pulmonic area may often be found by careful examination to be due to surface conditions, such as retraction of the anterior border of the left lung resulting from pulmonary collapse. They are not cardiac at all, and are of almost no clinical importance. (Fig. 5.)

Subclavian Murmurs.—Speaking of these murmurs reminds me of another that I might well have forgotten, since it is not really a cardiac murmur at all, but it is one that many of you must have noticed, and that is the loud systolic murmur making a noise like an escaping jet of steam, which is sometimes heard below the outer half of the clavicle, the left oftener than the right. You may have noticed that murmurs of this kind are louder during inspiration, and that they are increased when the arm is abducted from the side. The exact mechanism of the production of such murmurs does not concern us here; it is enough for us to know that they are produced in the subclavian artery under perfectly normal conditions, and have nothing whatever to do with cardiac disease. (Fig. 6.)

Venous Hum.—We are all familiar with the venous hum heard at the sterno-clavicular joints of the young child. At one time this murmur was regarded as a sign of enlargement of intra-thoracic lymph glands, but anyone who takes the trouble to carry out a systematic examination of a number of young children will soon convince himself that this idea is erroneous. It occurs in healthy as well as in unhealthy children, and my only reason for speaking of it here is that I have known it, when heard unusually low down in the chest, to simulate the to-and-fro murmur of aortic incompetence. I think it is a mistake one should be able to avoid, partly by noticing the essentially continuous character of the sound, which runs on from systole into diastole as these venous murmurs do, and partly also by observing the very pronounced effect exercised upon them by posture and respiration. (Fig. 7.)

Rules for Cardiac Examination.

This brings me to one important principle in the examination of the heart—namely, that one should never be content with examining the patient standing up only. It is also necessary, and particularly in the studying of murmurs, that the effect of lying down should be noted. It is also always prudent, I think, to take the further precaution of listening to the heart with the patient lying over on the left side. By this means you may often detect a presystolic murmur which might otherwise have escaped notice.

Another general principle to which I think we should commit ourselves is that a diagnosis of cardiac disease should never be made on the strength of a single physical sign, unsupported by any other signs, or by any history of subjective symptoms. You may object that this would exclude from a diagnosis of cardiac disease many cases of aortic incompetence in which the only evidence of the lesion is to be found in a diastolic murmur. Yet I doubt whether there are any patients with this lesion who are entirely free from subjective symptoms. It is a rule that applies even more to the proper appreciation of the meaning of arrhythmia than to that of murmurs, and I am sure it is a safe rule to be very suspicious of a diagnosis of cardiac disease based on the presence of arrhythmia alone.

A third principle which may often save us from error is that of endeavouring to visualise the actual changes in structure and function that are responsible for the physical signs that we may encounter. Take, for example, the case of a patient with an irregular pulse; I feel certain many mistakes would be avoided if we said to ourselves in every such instance, "In what part of the cardiac apparatus is the rhythm upset, and what function is it that is at fault?" A practice of this kind has this to commend itself, that it not only enables the observer to avoid individual mistakes, but that it also ingrains in his mind those principles of normal and morbid physiology on which the study of cardiac irregularities is based.

Now, if we were to practise these principles in everyday examinations of the heart, it is clear that it would take time; and the taking of time is a condition of practice that is not always easy to realise. Our masters, the public, are anxious that we should hurry up and get the maximum amount done in the minimum time. That this is a short-sighted policy from a national point of view was shown by our experiences during recruiting. The nation, having decided that recruiting should be done in a hurry, is surprised that that work was not done particularly well. It is true that it might have been done better, and nowhere was this more apparent than in our failure to distinguish between the real and the counterfeit in the matter of cardiac disease. Many of you must have seen, as I did, people passed as fit for military service who had serious organic disease of the heart. But this was as nothing compared with the hosts of those who, though perfectly fit for military service, were debarred from it by diagnoses of cardiac disease which ought not to have been made, and which would not have been made if it had been possible to give more time to the recruiting examination. So far as I have been able to judge, these hasty diagnoses of cardiac disease were in most instances founded on the discovery of a murmur, or of some form of irregular action, which a more leisurely examination would have shown to be unimportant in type and origin.

Risks of Mistaken Diagnosis.

Before I bring these somewhat desultory observations to a close, I may be able to express them in a more compact form by relating some of the circumstances under which we find ourselves in danger of making a diagnosis of cardiac disease where no such disease exists. First, there is the case of the child convalescent from some acute illness, such as bronchopneumonia. Under these circumstances we are, not unnaturally, and indeed rightly, on the look out for evidences of injury to the cardiac muscle. Often the state of anæmia which has been established by the causal infection is pronounced enough to produce a generalised systolic murmur of the "hæmic" type; and this, if it is joined with pronounced arrhythmia of the sinus type—as it often is—may tempt us to a diagnosis of myocardial disease and to a long period of unnecessary rest, injurious alike to body and mind.

The next case is that of the adolescent, more often a boy than a girl in my experience, who is found to have a fast and irregular pulse, with a banging cardiac impulse, and an unusually wide swing between the systolic and diastolic blood pressures. Usually he is tall and slender, having grown rapidly; and the afternoon urine often contains a trace of albumin absent from the morning specimen. Sometimes there is added to this counterfeit of cardiac disease a murmur, either of the cardio-respiratory kind found near the apex-beat or else general and "hæmic" in type. If we mistake these phenomena for evidences of cardiac disease and impose on the patient restriction from games and exercise, we are doing him actual harm by diverting body and mind into less wholesome channels.

The grown man, also, is not exempt from the danger of a mistaken diagnosis. The kind of case that is in my mind is that of a man who, while doing something laborious—for example, lifting a heavy weight—gets a pain in the left side of his chest. This pain returns when he gets home in the evening, and either at once or on the following day he sees his doctor. The pulse is quick and the beat of the heart forcible, and on these inadequate grounds a diagnosis of cardiac strain is made. Please observe that I do not ask you to agree that cardiac overstrain never occurs under such conditions. One man whom I saw quite definitely developed the total arrhythmia of auricular failure as a result of such a stress; and signs of aortic incompetence have been known to appear after a strain in persons previously innocent of any such lesion. In both of these cases, however, it is probable that cardiac disease in a latent form antedated the accident; in the familiar terminology of the Ministry of Pensions, the lesion is "aggravated," not "attributable." But this is a very different matter from the kind of case of which I was speaking before, in which, on the basis of a vague pain and a quick pulse, it is claimed that a previously healthy man has "strained his heart." It would not matter so much if the error were not magnified and exaggerated by the question of compensation, until return to work becomes quite impossible. What happens is this: The man is frightened in the first place by the thought that his heart is damaged, and this fear accelerates his heart. The quick beating confirms his fears, and from that time he looks forward to a return to his labours with the keenest apprehension, believing that it will be too much for him and cause him to drop dead. This continual atmosphere of apprehension increases and perpetuates the tachycardia, and so the vicious circle goes on until the man is an incurable ergophobiac. If he is young and without dependents it may be possible to persuade him, through the medium of remedial exercises and other forms of suggestion, that he can safely return to work; but if he is over 40 cure is well-nigh impossible, and in any case the compensation controversy will very soon succeed in arousing in the man's mind a spirit of resentment which makes him impervious to all talk of cure and return to work. The only way to avoid this tangle is to do all we can to prevent mistaken diagnoses of "cardiac strain" being made in the first instance. It is easy to agree openly with the man's fears, or to adopt a non-committal attitude, and difficult to take the risk of being wrong, and to say "*No;* your heart is quite all right, and you can safely return to work." Yet this course may perhaps save a man from permanent and distressing invalidism, and the risk is therefore worth taking.

TYPES WHERE ERROR ARISES.

Women at the menopause are notoriously prone to develop all kinds of visceral disturbances with corresponding subjective sensations. Among these is acceleration of the heart felt by the patient as palpitation, but extracardiac in origin and therefore of no significance as evidence of cardiac disease. A few days ago I came across a patient of this kind who had at the apex of the heart a systolic sound so like a murmur that at first I was in danger of writing it down as a sign of disease. This was heard while she stood up, but when she lay down it disappeared altogether, proving that it was exocardial and therefore without significance.

The only other example I have to offer is that of the elderly patient with frequent premature beats. Of these he is miserably conscious, either because of the apparent dropping of pulse-beats at the wrist, or because of the halt, followed by an abnormally forcible impulse, which makes him feel as if his heart had turned over, to use his own expressive phrase. Now, it is hard enough for any man to ignore these disturbances, and his only chance of doing so lies in mental pre-occupation. It is sometimes difficult to persuade him of his fitness for work, and if he is allowed to retire from business on account of his cardiac condition he will inevitably become worse; in trying to save his life he will lose it.

All these examples of difficulty in diagnosis must be familiar to every one of you, and it may be that in rehearsing them before you I have been guilty of wasting your time. My sole excuse for doing so must be that it has appeared to me that, at a time when we are taking more pains than ever before to make early diagnoses of cardiac disease, we must take equal pains to avoid diagnoses of disease where no disease exists.

PULMONARY TUBERCULOSIS IN CHILDHOOD.*

THE CLINICAL VARIETIES, DIAGNOSIS, AND PROGNOSIS, WITH AN ANALYSIS OF 165 CASES.

BY JOHN A. WATT, M.B., CH.B., D.P.H. ABERD.,
CLINICAL TUBERCULOSIS OFFICER, DERBYSHIRE COUNTY COUNCIL.

IT is generally accepted that tuberculosis of the adult is usually a reactivation of an infection in childhood; in this the child is truly father to the man. Consequently all efforts at prevention should begin in childhood. At that period the disease is usually curable, and the resulting immunity often ensures a lasting protection for life. Tuberculosis in many respects resembles another chronic infection of mankind—e.g., syphilis. In both there is a primary focus of infection constituting the first stage—cf. the primary lung focus of Ghon corresponding with the chancre; then in a short time involvement of the lymphatic system and spread of the organism throughout the body take place—the secondary stage; at a later period, and often years afterwards, destruction of the tissues takes place in both. We realise the importance of treating syphilis in the earliest stages, and for the same reason tuberculosis ought to be treated actively in childhood.

Type of Bacilli Present.

Pulmonary tuberculosis, which is the main source of infection for all other kinds of tubercle, is in the great majority of cases due to tubercle bacilli of the human type which enter the tissues through the respiratory passages. Bovine bacilli are rarely found in the sputum. A. S. Griffith,[1] in 1914, collected the investigations into the type of tubercle bacilli found in 938 cases by various workers; in 932 cases human tubercle bacilli were found in the sputum, 4 showed bovine bacilli, and 2 mixed strains. Investigation of the lung tissues themselves have not been numerous. The Royal Commission on Tuberculosis[2] examined the lungs of 14 cases of primary pulmonary tuberculosis and in each case only bacilli of the human type were found.

In young children it is not so uncommon for the lungs to be infected with bovine bacilli. Here the pulmonary disease is usually part of a widely-spread infection, and there may be caseation of the mesenteric glands, tubercles on the peritoneum, or ulceration of the intestine which show the origin to have been via the intestine. Cobbett[3] collected the investigations as to the lung tissues in 65 children dying from pulmonary tuberculosis; of these 61 showed human tubercle bacilli; four showed bovine, of which one was found in the lung, two in the bronchial glands, and one in the mesenteric glands.

Primary tuberculosis of the bronchial glands is nearly always caused by the human tubercle bacillus. Cobbett again collected 18 cases investigated by various workers, of which only one showed the bovine tubercle bacillus. He also summarises the results of 63 cases of generalised tuberculosis, excluding meningitis, which had been investigated by the Royal Commission and others; 10 of these, or 16 per cent., yielded bacilli of the bovine type, and they were usually in children under 5 years of age—leaving 84 per cent. due to the human tubercle bacillus. These investigations are of the greatest importance, for the constant presence of human tubercle bacilli in cases of pulmonary and bronchial gland tuberculosis is strong evidence that infection occurs from human sources, and infection through milk or food with the bovine tubercle bacillus is relatively uncommon.

---

* A paper read before the Derby Medical Society.

We may distinguish three main varieties of pulmonary tuberculosis in children corresponding to the pathological types of miliary, fibroid, and fibrocaseous disease. Clinically they are often termed: (i.) Acute, general or infantile; (ii.) hilum or juvenile tuberculosis; and (iii.) adult types.

Features of Pulmonary Tuberculosis in Infancy.

Tuberculosis in infancy runs a course like that of an acute infectious fever, with a marked tendency to generalisation somewhat resembling inoculation tuberculosis in animals. Infection seems rapid and easy, the bacilli reproduce quickly, and are carried by the blood-stream throughout the whole body. The disease runs a rapid and usually fatal course. On post-mortem examination the disease is widely distributed through the body. The bronchial glands are invariably involved and caseous, with disease spreading outwards from the roots to the periphery—both apex and base being affected. In the first year of life there is little tendency for the lesion to heal. Progressive caseation occurs, then dissemination, and miliary tuberculosis or meningitis is a frequent termination. Goodhart and Still[4] found that tuberculous meningitis was present in 114 cases out of 238 deaths of tuberculous children—i.e., nearly 50 per cent. It is the actual cause of death in nearly half the cases of tuberculosis in childhood.

Tuberculosis is more fatal in infancy than at any other age, and most fatal in the latter half of the first year and during the second year. The high mortality in infancy does not by any means represent the total number of deaths, for many deaths certified as due to bronchitis or pneumonia are really due to tubercle. It is highly significant that the death-rate from bronchitis in the United States of America is only one-seventh of the English rate—13 per 100,000 as against 89 per 100,000 in England.

Clinical Varieties.

General or Infantile Type.—The typical form is acute miliary tuberculosis caused by a hæmatogenous infection from an existing focus in the body, such as the bronchial or mesenteric glands. There occurs simultaneous deposition of bacilli in one or more organs with resulting miliary tubercles in such numbers as to produce a fatal toxæmia before the lesion has developed beyond the miliary stage. The tubercles will be in the same stage of development and approximately the same size. It can scarcely be doubted that small numbers of tubercle bacilli are often transferred by the blood and lymphatics to other parts of the body without setting up foci of disease. This depends upon the protecting forces of the body called into action, but the victim of miliary or generalised tuberculosis is incapable of developing this resistance or is overwhelmed by an excessive or virulent infection.

Acute miliary tuberculosis of the lungs is a striking picture, and the physical signs do not give an adequate idea of the disease. Both lungs may be studded with miliary tubercles and yet physical examination show only local or general bronchitis. The early symptoms are due to toxæmia. There is wasting, prostration, marked dyspnœa and cyanosis, slight cough and irregular temperature, slight at first, later with high range from 100° to 103° F. The physical signs are those of bronchitis, and gradually the clinical picture may merge into that of meningitis. As the disease progresses there may be tubercles on the choroid, and enlargement of the liver and spleen. In older children and adults the illness may closely resemble typhoid fever with delirium, enlarged spleen, tympanites, and a high temperature. A radiograph shows that tubercles scattered uniformly through the lung may be distinctly visible.

In generalised tuberculosis the lesions have advanced for the most part beyond the miliary stage, and the clinical picture is then dominated by disease of the organs showing the greatest involvement. A sub-variety—frequently unrecognised—is tuberculous bronchitis, seen in infants under 5 years of age, especially in homes where there is an open case of pulmonary tuberculosis. The history may show a period of depreciated health; the physical signs are persistent bronchitis which does not clear up, cough which may be "brassy," and irregular persistent temperature. The diagnosis is difficult. A positive von Pirquet reaction under 2 years of age is valuable. The finding of tubercle bacilli in the sputum would clinch the diagnosis. The signs gradually merge into those of caseous pneumonia or miliary tuberculosis with a fatal result.

Tuberculous Broncho-pneumonia or Caseous Pneumonia.—This is probably the most common form of pulmonary tuberculosis in infancy. It may occur as an acute disease, at first closely resembling an ordinary pneumonia. It may follow a tuberculous bronchitis, it may occur in the progress of abdominal tuberculosis, or it may come in the wake of the acute infections such as measles, whooping-cough, influenza, or typhoid fever in feeble and unhealthy children. Under 7 or 8 years of age it is rare to find any tendency to limitation by fibrosis. The caseous areas vary in size and number; they are often found in the lower portion of the upper lobes. A whole lobe, on the other hand, may be invaded. The pleura is always involved. Occasional cavitation is found, and more rarely, large cavities.

The symptoms begin like a broncho-pneumonia, except that the onset is more gradual. Cough is an early and constant symptom. Sputum can rarely be got unless the child is over 5 or 6 years of age, but the pharynx may be tickled with a cotton swab and the sputum caught as it is coughed up. Dyspnœa and cyanosis become prominent features as the disease progresses, and this at a time when an ordinary pneumonia ought to improve. The temperature is irregular and persistent. Anorexia is present, and vomiting and diarrhœa are common later on. There is a rapid loss of weight, and slight enlargement of the liver and spleen may be detected. There may be severe albuminuria and hæmaturia indicating involvement of the kidneys. The physical signs resemble broncho-pneumonia. Râles are heard generally, especially round the roots and in front of the chest. There will be scattered patches of consolidation. If a whole lobe becomes caseous the breath sounds will be greatly diminished over part of one lung. In infants this variety is usually fatal in one to four months. In older children the caseous process may become limited by fibrosis and assume a chronic form. Such cases resemble closely the chronic forms of non-tuberculous pneumonia, especially the streptococcal type.

A radiograph shows the hilum shadows to be increased in size. The whole field of both lungs is dotted with rounded, sharply defined areas of opacity of the same size and equally distributed. Later on these areas may coalesce when large dense shadows are produced. It must be remembered there is no clear demarcation between these varieties of acute tuberculosis in infancy; a case may die in the miliary stage or it may progress into the broncho-pneumonic. In all a shower of tubercle bacilli has been scattered by the blood-stream over the body and bacilli may be present in all the organs. The physical signs depend on the duration of the disease and the stage the tubercles have reached.

Pulmonary Tuberculosis in School-children.

When the child reaches school age the disease enters on a new phase. It now passes into more latent and chronic forms, with a lower death-rate between the ages of 5 and 15 than at any other period of life.

The common form is now a benign and latent glandular infection contracted in infancy. We know that nearly all town-bred children are infected with the tubercle bacillus, and by the age of 15 anything from 60 to 90 per cent. of the population in large communities give a positive von Pirquet's test.

Paths of Infection.

Careful investigations have been carried out by Kuss, Allbrecht, and Anthony Ghon[5] into the channels of infection in childhood, originating through inhalation. The primary focus Kuss believed to be a small tubercle usually situated subpleurally, but often intraparenchymatous. Usually only one primary focus exists, and the size varies from a pinhead to a hazel nut; it is well defined, often enclosed in a fibrous capsule, and consists of dry and hard or soft caseous masses. The lymphatic bronchial glands draining the area in which the lung focus originates nearly always become tuberculous, but these cannot usually arrest the bacilli, and infection progresses to the lymphatic glands in the mediastinum. These latter are the first barrier against the progress of the infection. Kuss said this intrathoracic tuberculosis forms the first stage of the infection of the individual and usually remains passive. But the infection may spread further, and in time ends in a clinically recognisable form of tuberculosis in which the lungs are affected by a retrograde movement.

H. Albrecht, in 1909, studied the primary infection of the lung in a series of 1060 autopsies of tuberculous children. The primary infection he represented as an isolated focus usually round, of varying size, often caseous, and containing in the centre a thin fissure as a remnant of the caseous bronchioles. There was usually only one focus. The focus may appear in any part of the lobe, and by fresh tubercles at the periphery may attain to the size of a cherry or larger. Only in a small number of cases was he unable to find the primary infection. Corresponding to the primary infection are caseous tracheo-bronchial lymphatic glands which correspond to the side of the lung focus, or at least show more advanced lesions than on the other side. These results were further confirmed by Ghon, and they all claim that the primary infection of the lung is aerogenous. This view is not universally accepted, and there are many eminent investigators, such as Calmette, von Behring, among them, who believe that the usual channel of infection is through the intestine and mesenteric glands —i.e., that ingestion is more important than inhalation. Though infection may occur through this route it is most likely not of frequent occurrence, and the majority of workers think that tuberculosis of the bronchial glands is due to tubercle bacilli inhaled directly through the respiratory passages.

The primary lung focus gives rise to secondary infection of the thoracic glands, and usually the disease is arrested here. If the disease is confined to the thoracic glands there may be few, if any, physical signs and the symptoms become all-important. This infection usually covers a period of impaired health of from 12 to 18 months. It is benign, and nearly always ends in arrest and recovery. On the other hand, if immunity should be low, the disease spreads outwards, showing in a radiogram as mottling round the roots, gradually spreading further into the parenchyma of the lung. This is the condition we speak of as hilum tuberculosis and the French as "ganglion pulmonaire."

Hilum Tuberculosis.

General Symptoms.—There is exhaustion after light physical or mental effort. Children lose their activity and are disinclined for games. In the hospital class malnutrition is a striking feature. There is loss of weight, or there may be no gain in weight for long periods. The appetite is poor. Irritability and change of disposition is often marked. Night sweats may occur, but they are common in other diseases of childhood and may be due to deficient ventilation of the bedroom. In rickets sweating is confined chiefly to the head and neck and occurs shortly after the child goes to sleep; in active tuberculosis it occurs between 2 and 4 A.M. and may soak the bedclothes.

Cough.—Cough may be absent or very slight, especially in infants. It may be catarrhal, as in bronchial catarrh. It may be barking and dry like whooping-cough, attributable to pressure symptoms on the vagus or other structures. Cough by itself, however, is not of high significance, as it is so frequently due to the catarrhs of school life. There may be bronchitis. In a one-sided bronchitis tuberculosis suggests itself. Asthma is a rare complication. Attacks of slight dry pleurisy are frequent.

Temperature.—The normal temperature in children is subject to wider fluctuations than in adults—occasional rises to 100° may occur in health. One should not place much reliance on small rises of temperature. In older children the maximum temperature is reached earlier in the afternoon than in adults, and a fall of one or two degrees in the evening is characteristic. Continuous temperature over 100° should always arouse suspicion, but the absence of fever does not exclude tuberculosis.

History of Infection.—The tuberculous infant is found in a tuberculous family. It has been established in Paris that the infection of a child is nearly always due to contact with a tuberculous parent. A very brief exposure lasting only a few days is sufficient for the production of tuberculosis in the newly born. Debré and Léon Bernard say the only children to escape contagion are those who live less than six months with a tuberculous mother. A case of open tuberculosis in a household has a sinister influence upon all young life. In such homes infection occurs early; more than half of the children are estimated to be infected before they are a year old. Pollack in 1911 made interesting investigations into the fate of children living in tuberculous homes. He found that children infected during the first five years of life, if they survived, usually showed clinical signs of tuberculosis. Bergman in 1919 confirmed and supported this idea. He investigated thoroughly 233 tuberculous families, including 1004 children from birth upwards, and in one-third of these has traced them far up into adult life. His conclusions briefly are: Every one of the persons who had died of tuberculosis in childhood or adult life, and nine-tenths of those who were still living but suffered from clinical tuberculosis, had been exposed to infection within the first four years of life. On the other hand, not a single death from tuberculosis could be found among those whose exposure to tuberculous infection had been deferred until after the fourth year. Further, not one case of clinically demonstrable tuberculosis in any form could be found amongst those whose exposure to infection had been deferred till after the seventh year of life. Of 698 persons who, in the first year of life, had lived in tuberculous surroundings, 277, or 40 per cent., had either died from tuberculosis or showed the disease in a clinical form.

Physical Examination.—Children suffering from tuberculosis of the thoracic glands are often of poor physique and delicate-looking, but children showing every indication of good health may suffer from disease of the bronchial glands. The fine and coarse types usually described have been made too much of. An overgrowth of soft, silky hair between the scapulæ and on the arm is often seen in septic conditions, and in children in whom no evidence of tuberculous disease can be found. Prominent or dilated veins on the front of the chest, usually on the right side, sometimes on both, have been noted. Spinal telangiectases centring round the first and second dorsal spines and attributed to pressure symptoms have been considered characteristic. The venous signs are all uncertain; they occur in pale, thin children, and in a large proportion of healthy children. General glandular enlargement or chains of glands running down the cervical region are usually tuberculous, but they occur in other infections and in rickets. Enlargement of the supraclavicular glands should be looked for, and if present suggests involvement of the apical pleura. Enlargement of the submaxillary and upper cervical glands is common in school-children, and occurs in diseases of the tonsils, teeth, and other inflammations of the skin and scalp caused by dirt. Enlargement of the mesenteric glands should be sought for; they are sometimes palpable just to the right of the umbilicus. Phlyctenular conjunctivitis is often seen in children infected with tubercle.

Percussion.—Riviere [6] says there is 1 cm. of normal impairment of resonance on each side of the sternum between the first and second ribs, which he calls the parasternal dullness, and believes that this may be increased up to as much as 4 or 5 cm. or 2 in. when disease of the thoracic glands is present. I have got no assistance in diagnosis from parasternal dullness. Increased paravertebral dullness is often found, and I look upon it as the most important percussion sign. The normal oval interspinous dullness extends about one inch on either side of the middle line between the spines of the first and fifth dorsal vertebræ, but it varies much in amount. In hilar disease the area is increased and may extend out to two inches or more. Enlargement of the area appears first on the right side corresponding with the greater enlargement of glands along the right bronchus. In more extensive disease the left interspinous dullness is also increased. When the disease spreads out from the hilum into the lung, resonance tends to be impaired towards the apices or bases. Krönig's area, which is so useful for the diagnosis of hilum tuberculosis in adults, is difficult to map out in young children owing to the smallness of the parts. After the age of 10 its width can be determined easily.

Auscultation.—The signs vary very much. There may be light bronchial breathing under the clavicles or at one or both sides of the upper vertebral spine. There may be harsh, rough, low-pitched, or jerky inspiration, or there may be weak breathing over the whole or part of a lung from pressure on a bronchus. The signs by auscultation are heard most distinctly in the posterior region. Fleeting, scattered, persistent crepitations may be heard around the nipple region. If infiltration spreads into the lung, closely set, moist crepitations may be heard at the bases.

D'Espine's Whisper Sign.—D'Espine [7] described it as a whispering echo following the spoken voice, and heard on auscultation over the upper dorsal spinous processes. He believed, too, that the bronchial character of the spoken voice did not normally extend below the seventh cervical spine. Of these two signs the whispering echo following the spoken voice is the earlier. The bifurcation of the trachea varies according to age. In infancy the trachea divides about the level of the first dorsal vertebræ, but by the age of 12 the division is opposite the fourth. In applying d'Espine's test a number may be whispered or spoken distinctly and is listened to either by the direct ear or the stethoscope. The characteristic tracheal sound may be heard downwards as far as the fifth or six dorsal vertebræ. Much [8] says that up to the seventh year the sign is heard normally to the seventh cervical spine, from 8 to 12 it reaches to the second dorsal spine, and after the age of 15 to the third dorsal spine. This sign is of considerable value, but is reputed to occur in cervical adenitis, chronic disease of the nose and tonsils.

Examination of the Sputum.—Infants and young children usually swallow their sputum, but it is not difficult to get a specimen from older children. It should always be sought for and an examination made by one of the concentration methods. The approximate number of bacilli seen in the whole film is then counted. The frequent association of positive results in the sputum of children showing clinical signs of pulmonary tuberculosis leaves no doubt in my mind that if acid-fast bacilli are found in the sputum, it means the tubercle bacillus.

It will be seen from the table that nearly 50 per cent of hilum tuberculosis cases showed the presence o tubercle bacilli at some time or other—either at th dispensary, the sanatorium, or both. I do not mea that you will find the bacillus in 50 per cent. of th hilum cases. Owing to the small number of bed available for children, the cases selected for treatmen in the sanatorium were for the most part definit cases with bacilli present. This accounts for the hig proportion. In an investigation by Stewart [9] dealin with 158 children at the City of Birmingha Sanatorium, Yardley-road, he found six positiv sputum results—i.e., 3·8 per cent.; while Holt, b tickling the pharynx with a piece of muslin held i a pressure forceps and wiping up the secretion durin the resulting cough, was able to demonstrate th tubercle bacillus in fully 80 per cent. of cases of lun disease in young children.

Radiography.—Screening or fluoroscopic examination of the chest is never sufficient—a radiogram mus be taken. After the examination of the sputum it i the most important aid to diagnosis. The thorax o the child permits penetration by X rays easily. U to the age of 5 the lung is pretty clean in a health child; later on the radiograph is shadowed with pas lesions. The hilar shadow produced by lymph glands bronchial tubes, blood-vessels, and connective tissu extends upwards to about the fifth rib posteriorly, an downwards till it crosses four ribs, its width and densit varying greatly in health. The lung fields show n markings in the outer zone, and in the young none i the middle zone.

The normal chest of the child should show (1) Translucent pulmonary fields with good illumination on deep inspiration; (2) proper movement of th ribs and diaphragm; (3) a radiogram with insignificant hilum opacities and at the outside only a fe radiating peribronchial striæ, accompanied by a trivia number of small and obsolete focal shadows.

The tracheo-bronchial glands when diseased for a shadow outside and parallel to the sternum, stretching from the clavicle down towards the hilum acros the posterior second, third, and fourth intercosta spaces. They may form a dense shadow showin within the lumpy rounded shadowing of caseou glands. They are most easily seen and most commo on the right side, as the aorta and other structure obscure the left hilum shadow. Enlarged bifurcatio glands are only visible in an oblique radiogram whic will show the trachea and its bifurcation. In th angle between them appears the shadow of th bifurcation glands. Riviere says this shadow i practically never absent, for the bifurcation gland are nearly invariably affected with tubercle. It i doubtful if tuberculous glands show radiographicall unless they have passed the stage of congestion an enlargement and have become caseous or calcareous

As soon as disease extends from the intrathoraci glands to the lungs infiltrating them, X rays show it presence. Hilum tuberculosis shows first as a increase in the size and opacity of the hilum shado then the edges become diffuse, cloudy, and indefinit There may be spread along the interlobar fissures an from these opacities shade into the clear parenchyma Striated or lamellated shadows following the contou of a lobe are important; usually these begin nea or at the hilus and radiate towards the peripher Advanced and extensive tuberculous disease is usuall easily photographed and interpreted.

Prognosis.—Hilum tuberculosis in children if confined to the thoracic glands is usually a benign diseas the activity covering a period of 12 to 18 month and nearly all cases recover. The infection is s mild that it is usually not recognised and must ofte cause little or no disturbance to health. It should b looked upon as an inevitable, and possibly a beneficen accompaniment of communal life. If we were n immunised in childhood we might die like primitiv races and American Indians. When glandular diseas spreads into the lung it extends slowly in children o school age, smouldering on for years, often unrecog ised, and waking into slight activity with each fresh atarrh. There is evidence accumulating that hilum uberculosis may develop in adolescence into the adult ype as we know it. The spread of tuberculous disease rom the hilum towards the upper lobes is often seen, nd its development can be recorded in a series of adiograms. I have seen not a few cases, suspected en years ago to be suffering from hilum tuberculosis, hich have reached the age of adolescence and died rom the ordinary adult type of disease. From this oint of view the average duration of the disease from afection to death may be put at 15 to 20 years.

The table shows 117 cases of hilum tuberculosis ut of 165 cases admitted to the county sanatorium. fter an average period of two to three years there as been one death, and 12 cases were reported as orse. Gibson and Carroll[10] record 131 cases of intrahoracic tuberculosis, classifying them adult type 34, ivenile or hilus 74, tracheo-bronchial 23.

Adult Types.

These are not common before the age of 12, but ncreasingly frequent thereafter. They give little ifficulty in diagnosis, for the symptoms and signs losely resemble those found in adults. Involvement f the upper lobes is most frequent, and the right lung ore often than the left. There is toxæmia, impairment f resonance, bronchial breathing, crepitations at the pices or over a lower lobe, or extensive distribution eading to cavitation. Tubercle bacilli are usually resent in the sputum, and X ray examination will how the extent of the disease. Gibson and Carroll uote 34 cases of this type, with cavitation in 9 and ubercle bacilli in the sputum in 18 of these. My gures show 48 cases cf the adult type out of 165 dmitted to the county sanatorium; 37 had tubercle acilli present in the sputum, a percentage of 77. he youngest child I have seen showing this adult orm was 6 years of age. O'Brien and Ames[11] investiated clinically and radiographically 44 infants and hildren at the Boston Consumptive Hospital. They ound nine cases under 10 years of age suffering from hronic pulmonary tuberculosis of the adult type, and wo under 6 years of age. The prognosis in this form s serious; over a third of the children were dead ithin an average period of three years.

BRONCHO-PULMONARY SPIROCHÆTOSIS.

BY DR. Y. SCHWARZ,
CAIRO.

BRONCHO-PULMONARY spirochætosis was described for the first time by Castellani in 1904. He discovered the first cases among the natives of Ceylon. Shortly afterwards, Waters found similar cases in India and Jackson in the Philippines. In 1918 Violle described an epidemic of broncho-pulmonary spirochætosis which raged at Toulon. The first cases treated there were Chinese and Indo-Chinese, then Senegalese and the Malgachs; a month later some French patients were admitted to hospital for the same disease described by Violle as very contagious. At the end of 1919 Najib Farah described 10 out of many more cases of broncho-pulmonary spirochætosis studied by him in Egypt (at Alexandria).

Since 1904 observations have been published by Branch, Chalmers, Taylor, Phalen, O'Farell, Gali-Valerio, Simon and Raditch, Prengault and Mercier, Lurie, and others, and cases have occurred in Europe, in the Balearic Islands, on the shores of the Adriatic, in Switzerland, in Serbia, and in France. It is therefore not necessarily a tropical disease, as was thought at first, but one which can be met with in different climates and amongst various nations.

The disease, however, has been insufficiently investigated, and the observations hitherto published are contradictory on more than one point. Its importance, though, cannot be denied; it lies less largely than is thought in the fact that it has always been clinically confused with the pulmonary tuberculosis which it resembles in certain respects, but from which it differs by being susceptible of sure and rapid cure.

Symptoms and Signs.

Broncho-pulmonary spirochætosis is a disease provoked by the localisation in the respiratory tract of a spirochæte termed the spirochæte of Castellani. In acute cases we find fever, headaches, stiffness in the back and limbs, dry coughing, and sometimes hoarseness and retro-sternal pains. The examination of the chest shows signs of bronchitis with diffused sibilant and sometimes, in some areas, subcrepitating râles; sometimes, also, some slight dullness at a summit or base. The expectoration is mucous at the beginning, then muco-purulent, often with streaks of blood. Sometimes the sputum is completely bloody, and real hæmoptysis has also been met with.

The acute cases, considered as very contagious, have generally an incubation period of one to three days. The fever remains during four to five days at about 39° C., then the symptoms improve little by little and a cure ensues. In certain cases the disease prolongs itself for five or six weeks, and cases have been described with many relapses and a tendency to become chronic.

Castellani quotes a case which lasted six years, the patient having the aspect of cachectic tuberculosis. Of the ten cases described by Najib Farah eight were chronic. In two of them the disease had lasted eight and four years. Coughing began either acutely or insidiously, and in various degrees of severity. The expectoration varied in quantity and character in different patients. In seven cases the sputum was bloody and frequent hæmoptysis occurred. The temperature in the chronic cases was habitually normal

or a little above it. In one instance there was hectic fever during 20 days. The physical signs were either null or else agreed more or less with those of the acute cases described by other authors.

Clinical Records.

I shall postpone until later my description of the pathogenic agent and pass now to my personal experience of cases.

The first was a young Egyptian girl, aged 18, whom I saw in 1921. She had been ill for eight or nine years and had scarcely left her bed since the beginning of her illness.

History.—Family and personal history insignificant. Precise details as to the beginning of the illness are wanting, but can be imagined from the successive diagnoses of her physicians—influenza, bronchitis, and colds. The sputum, streaked with blood, had been frequently examined for T.B., always with negative results. Sometimes the blood would disappear from the sputum for a few days, but regularly recurred. There was also occasional slight hæmorrhage in quantity, varying from one to two tablespoonfuls. The fever, which at the beginning remained high for periods of two weeks or a little more—with remissions of some days, sometimes a week or two—had been nearly constant for a year or two, and often reached 40° C. She had never menstruated.

She had undergone various treatments at the hands of a number of physicians, but chiefly symptomatic, and in 1918 she was operated on for appendicitis. The operation had no influence on the course of the illness, and I mention it chiefly to show the difficulty in the correct diagnosis of the case. She was finally treated as tuberculous and removed for a change of air to a sunny station in the vicinity of the town. This diagnosis had been the most frequent during the illness.

Her general appearance by no means agreed with the gravity of the symptoms described. The girl was indeed pale, a little thin, and with dark circles round the eyes, but she was far from presenting the cachectic aspect that would have accompanied a tuberculous illness of such duration and with such fever. When examined no pulmonary mischief could be detected, as one would naturally expect, in a case of pulmonary tuberculosis of so long standing. There was only a very slight dullness in the right subclavicular space, and some sibilant and subcrepitating râles diffused over the whole extent of both lungs. The patient also had an advanced pyorrhœa alveolaris and her breath was fœtid.

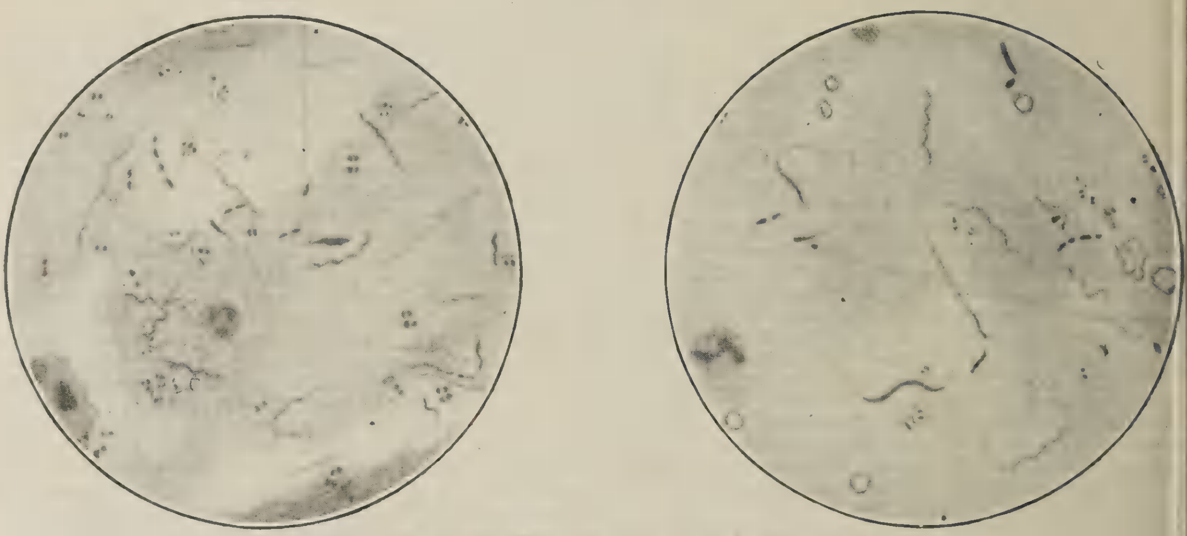

Fig. 1.

Fig. 2.

Spirochætes of Castellani. Films of sputum stained with gentian-violet.

I had thought for a moment of syphilis of the trachea and bronchi which is sometimes accompanied by hectic fever and can simulate tuberculosis, and had a Wassermann made which showed itself feebly positive. Further examination showed very numerous Castellani spirochætes in the sputum and this established the diagnosis. She received eight weekly intravenous injections of neosalvarsan in doses of 0·15, 0·20, 0·30, 0·45, and three of 0·60 cg. It was only after the seventh injection, the second of 0·60 cg., that the temperature, which during all that time oscillated between 39° and 40° C., began to fall. It reached normal in the space of a few days. The sputum, which at that time was still bloody, remained so for some time, bu with intermissions which grew longer and longer. A few weeks after the last injections the hæmoptysis definitely ceased. Since her recovery, more than two years ago, she has gone out and enjoyed life like others, and with the exception of a certain weakness of constitution, intelligible after confinement to bed of more than eight years; she has had no recurrence of any of her former symptoms.

As in all my cases the disease did not show itself contagious, even for the patient's sister, who nursed her for so many years.

My second case is that of an Egyptian lady, who came to me in 1922. She complained of sensations of tingling in the tongue and throat. She had felt those organs swollen dry, and numb. For three or four years she has had slight hæmorrhages at different times, the blood coming as much from the nose as from the mouth. She had cough and palpitation on effort, and snored in sleeping. It is to be noted that it was especially for the sensations in the throat and tongue that she consulted me, for the hæmoptysis had been attributed to tuberculosis by so many physicians, while she had so slight symptoms that she finished by paying little attention to it. There was no fever, and at the examination I could only remark some râles at the left apex, a cracked tongue, and a pyorrhœa alveolaris. I made at once some films of her sputum, stained them, and found a number of fusiform bacilli and spirochætes identical with those of Vincent's angina, but no T.B. With the exception of a certain diffused redness of the pharynx there had been none of the symptoms which characterise the angina of Vincent.

An intravenous injection of 30 cg. of neosalvarsan followed by another of 0·60 cg. seven days after, brought about the disappearance of the bronchial and other symptoms I have never been able to convince her relations that it was not tuberculosis that I had cured, but quite another disease and they have not ceased to send me cases of authentic tuberculosis, for which, of course, I possess no miraculous specific.

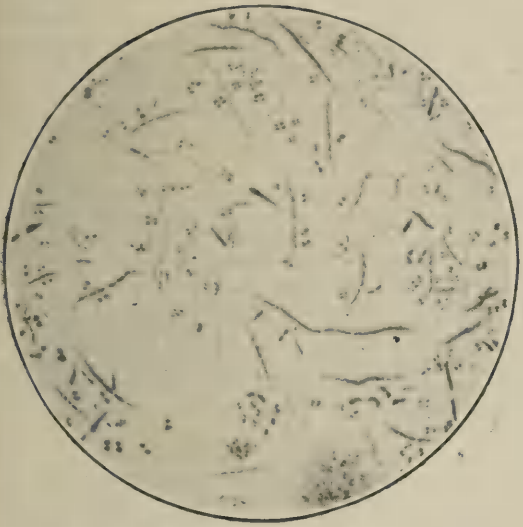
My four other cases are similar, all having some cough and sputum, sometimes streaked with blood pyorrhœa alveolaris always, and few or no pulmonary signs. Spirochætes were always visible with the ultra-microscope or after staining; there was no fever, and in general the symptoms were very benign The treatment was the same as for the preceding cases described and the result identical.

Pathogenesis.

The broncho-pulmonary spirochætosis is due, we have said, to the localisation in the respiratory tract of the spirochætes of Castellani. This organism (see Figs. 1 and 2) displays a polymorphism that is considered characteristic. Forms can be seen, long or short, slender or thick, and they are found sometimes matted together. Their mobility is great, and they have sometimes the appearance of a vibrating cord, sometimes of an eel undulating slowly through obstacles. Their length varies from 5 to 25μ and their width from 0·2 to 0·3μ. Like all the protozoa their culture is difficult and until lately was considered impossible. However, certain authors have recently reported success.

There is a tendency to group together the various parasitic spirochætes of the mouth, teeth, pharynx, and bronchi, and to consider them if not a single species, at least as capable in such localities and conditions of provoking identical lesions and symptoms. The fact that all my cases presented pyorrhœa alveolaris supports this view. It even throws doubt on the separate identity of the fusiform bacilli and the spirochætes of Vincent, the agents of ulceromembranous angina. The films obtained with the sputum of my second case named gave results identical with those obtained in the most typical cases of Vincent's angina. However, we must note one extremely important detail, that this case presented none of the symptoms characteristic of that disease. It is, I think, the first case described of sanguinolent bronchitis provoked by this fuso-spirillary association. This case powerfully supports the above hypothesis. But the film referred to is still interesting on another ground, for it shows forms resembling fusiform bacilli by the presence in their thickness of some traces of the vacuoles which characterise these bacilli and also resembling the spirochætes in their form (see Fig. 3). The thickness is intermediary to both. They appear to be transition forms between the fusiform bacilli and the spirochætes. The fusiform bacillus in this case is not to be considered a bacillus, but in my opinion a sort of encysted form of the spirochæte, which therefore is to be looked on as the adult form of one and the same protozoon. The Wassermann reaction is in general negative in cases of broncho-pulmonary spirochætosis. However, in my first case it was feebly positive, and I attribute this to the very long duration of the illness (eight years).

FIG. 3.



Association of *B. fusiformis* and fuso-spirillary organisms of Vincent with transition forms.

Violle affirms that the spirochætes which exist as parasites in the buccal cavity and which (in certain cases ill determined) propagate in the neighbouring parts, provoking various lesions (pyorrhœa alveolo-dentaire, Vincent's angina, broncho-spirochætosis of Castellani or bloody bronchitis), seem to originate from the soil. Man seems to become infected by the ingestion of raw fruits, vegetables, &c., badly cleansed from the damp earth which covers them. The fact that all my cases presented pyorrhœa alveolaris and that some of them averred that the pyorrhœa had preceded the bronchitis, inclines me to the hypothesis that this would be the first localisation and richest in the spirochætes.

Diagnosis.—This is established by the presence of the polymorphous spirochætes in the sputum. Any patient presenting vague symptoms of bronchitis and sputum tinged with blood should be suspected of bronchial or broncho-pulmonary spirochætosis, and his sputum examined from this point of view. The absence of definite pulmonary symptoms must be considered an indication of the disease. It is from tuberculosis that the differential diagnosis has to be made. Radiography may be of some use, by giving negative results in cases of spirochætosis, but it is always the microscopic examination of the sputum that determines the diagnosis. The spirochætes are easily recognised by the ultra-microscope, or rather by microscopic examination on a black background. They are seen alive, very mobile, and presenting all the characteristic movements of various spirochætes. The films may be stained by numerous methods. I found it simple to stain them slowly (from 10 to 15 minutes) with carbolic-gentian-violet, the results being very clear and of easy interpretation. The only inconvenience of the method is that the slides thus stained are difficult to preserve. I had the disagreeable surprise of not being able to distinguish the spirochætes (although all the other elements could still be seen very clearly) in slides thus stained and preserved for some months with Canada balsam. By chance I found that after a treatment by xylol for 24 hours and a fresh stain I could again distinguish the spirochætes as distinctly as before.

Prophylactic treatment of broncho-pulmonary spirochætosis consists in avoiding the ingestion of raw and insufficiently washed fruits, vegetables, &c. Serious attention must be given to the hygienic care of the mouth. The pyorrhœa alveolaris, from this point of view, as for other reasons, must be regularly and thoroughly treated. Microscopic examinations of the pus ought to be made with more regularity than is usually done, and the discovery of any species of spirochætes in a case of pyorrhœa ought to justify a treatment by neosalvarsan, all the more so because mild doses are often sufficient.

As a *curative treatment* neosalvarsan has, according to the majority of authors, given definite results. But it has not satisfied others. Dr. Najib Farah employs only iodine, under the form of lipiodol, in daily intramuscular injections, then spaced, of 2 c.cm. each. He states that he has always had very good results. In any case this treatment has the disadvantage of its length.

My cases have always been cured after one or two intravenous injections of neosalvarsan, except the case of eight years' duration, in which, as I have said, a greater number of injections was necessary. It is, perhaps, on account of insufficient doses that authors have reported failure. In this patient it was only after the seventh injection (the second of 0·60 cg.) that the temperature began to fall and the patient to recover.

Conclusions.

I sum up my conclusions as follows :—

1. There exists a broncho-spirochætosis, chronic from the first and not contagious.
2. The fuso-spirillary organisms of Vincent may localise themselves in the bronchi and provoke a bronchitis of the Castellani type.
3. There exist intermediate forms between the fusiform bacillus and the spirochæte of Vincent, and the hypothesis that the fusiform bacillus is but an encysted form of the spirochæte is a reasonable one.
4. The spirochæte of Castellani may influence in the positive sense the reaction of Wassermann.
5. Pyorrhœa alveolaris seems to be the first localisation of the various spirochætes which, on reaching the bronchi, may give rise to broncho-spirochætosis of Castellani.

6. Neosalvarsan, in intravenous injections and with sufficient doses, is the effective remedy for this spirochætosis.

From a practical point of view I have brought together the cases observed by me with those described at Alexandria by Dr. Najib Farah, and I agree as to the probable frequency of cases of broncho-pulmonary spirochætosis in Egypt, and attribute them to the same causes that determine in this country the frequency of pyorrhœa alveolaris—that is to say, a want of alimentary hygiene, and insufficient attention paid to the hygienic care of the mouth.

TRIGONITIS AS A CAUSE OF IRRITABLE BLADDER.

By T. E. Hammond, F.R.C.S. Eng.,
ASSISTANT TO THE SURGICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF.

The term "irritable bladder" does not denote any particular disease but refers only to certain conspicuous symptoms. In the past it has been loosely employed in cases where frequent and painful micturition was present, and was in common use about the middle of last century. The introduction of the cystoscope and X rays has led to a more accurate and an earlier diagnosis, and we now prefer to speak of the particular disease rather than of the predominant symptom. But there is still a class of case where, notwithstanding a careful examination, no definitely recognisable pathological condition is to be found; to this class the term "irritable bladder" may still be applied.

The act of micturition is to a certain extent under the control of the will. The number of times it is performed during the day varies with the individual, and is dependent upon habit and temperament. Normally it is four to seven times; this number may be increased during cold weather, after drinking large quantities of fluids, and during periods of mental strain.

The chief causes of prolonged increases of frequency are the following: (*a*) Polyuria due to such diseases as diabetes, chronic nephritis, or high blood pressure (hyperpiesia). (*b*) Changes in the urine such as hyperacidity or excess of the normal constituents—e.g., oxaluria. (*c*) Infections of any part of the urinary tract. (*d*) Diseases of the kidney such a stone, tuberculosis, or hydronephrosis, which may act reflexly or by giving rise to polyuria. (*e*) Diseases of the bladder and urethra such as stone, new growth, or tuberculosis. (*f*) Those conditions which diminish the capacity of the bladder or prevent its being completely emptied such as stricture or enlarged prostate in the male, and cystocele, or tumours of the uterus and ovary in women. (*g*) Reflex causes from diseases in neighbouring organs, particularly the rectum and genitalia.

Each of these has a recognised pathological basis, the removal of which should cure the complaint. But the condition I am now about to describe has received little attention in this country, and we know practically nothing of its pathology. It was first described by Knorr[1] in 1900; since this time several articles have appeared in America, where it has been called cystitis localised to the neck of the bladder (cystitis colli),[2] or trigonitis, the name originally given by Kelly. References are to be found in French text-books, where it is referred to as *la cystite partielle* or *la cystite du trigone*[3]; but it seems that some of the cases described under *la névralgie vésicale* and *la neurasthénie urinaire*[4] should be included. Though the expressions irritable bladder and trigonitis crop up, I can find no definite account in recent British literature. It is more common in women, and descriptions have generally come from gynæcologists; it is, however, also found in men. Some of the conditions attributed to lesions of the prostate, but in which no pathological changes can be detected in the gland, should be included.

Ætiology.

It is seen most often between 40 and 55, the period during which in women involutionary changes are taking place in the neighbouring sexual organs. It may arise during pregnancy, but is more common after labour, particularly if there has been some infection of the urinary tract. It follows inflammation of the neighbouring organs—e.g., salpingitis and appendicitis—but is not common in uncomplicated tumours of the uterus and ovary and such conditions as cystocele. Pelvic operations are common precursors, especially if they set up retention of urine.

Symptoms are present in infections of the urinary tract only so long as the infection is kept up, when pus and bacteria are to be found in the urine. But sometimes irritability of the bladder with a clear urine may persist. Trigonitis may follow gonorrhœa, but in my cases a history of gonorrhœa is not common. It sometimes arises after acute infectious diseases such as influenza. Hurry Fenwick[5] has referred to the obstinate and severe neuralgias of the lower urinary tract that followed an epidemic of Russian influenza. In some of my cases that followed an attack of influenza an infection of the urinary tract was undoubtedly present at the time; but in others the evidence is not very definite. A history of typhoid fever was obtained in one of my cases, but no bacteria could be cultivated from the urine. In 40 per cent. of the cases no abnormality of the pelvic viscera can be detected, nor was there any evidence of a preceding urinary infection.

Symptoms and Course.

While the onset is usually insidious, it may be very acute when an infection of the urinary tract is probably the primary cause. Increased frequency of micturition during the day and later during the night is the first symptom. It is more marked after exercise, exposure to cold, or any indiscretion in diet. Pain that may be referred to the neck of the bladder, to the perineum, or to the external meatus, is common. It sometimes radiates to the sacral and lumbar regions. It is not relieved by rest; while sometimes most intense before and during micturition it is generally most marked at the end. It may be extremely severe, and there may be acute paroxysms unrelated to micturition. In some cases only a slight burning pain or a feeling that the bladder has not been emptied is present. There may be urgency of micturition and also a little difficulty in starting the stream. Sometimes there is a history of hæmaturia.

Though the symptoms may remain stationary for years and periods of complete remission may occur, the course is gradually progressive, and sooner or later the general health becomes undermined.

Examination.

The urine is generally clear and sparkling and contains no visible pus. Its reaction is variable. A trace of albumin may be present. The centrifugalised deposit shows an excess of epithelial cells, some red cells, and occasional pus cells. Bacteria are rarely found on examining a drop specimen or the centrifugalised deposit of the recently passed urine. The *Bacillus coli* or staphylococcus may be grown on culture. But I do not attach much importance to their presence unless they can be detected in the freshly passed urine, as the possibility of contamination from the urethra cannot be excluded. Occasionally there may be an appreciable amount of pus; but in these cases cystitis and infections of the kidney must be carefully excluded. While the general health may be good, these patients are often very neurotic and introspective.

Cystoscopy.

There is often much pain as the cystoscope passes over the proximal part of the urethra and the neck of the bladder. The capacity of the bladder is not diminished; it can hold ten ounces without discomfort. The walls and ureteric orifices are unaltered. The trigone is congested and thickened; this may be so intense as to give an appearance of red velvet. The line of demarcation from the healthy bladder wall is usually very distinct. Œdematous patches are not uncommon, especially in the neighbourhood of the internal sphincter. The papillæ may be much swollen and hypertrophied and may resemble true polypi. Scattered red spots like petechiæ and small shallow ulcers may be seen. In two cases where the pain was very severe there were linear ulcers in the region of the sphincter bearing a strong resemblance to an anal fissure. The congestion extends into the proximal part of the urethra, involving the posterior more than the anterior wall. In the male the verumontanum may be congested and hypertrophied. In women the lesion is most marked over the trigone; in men in the prostatic urethra.

Diagnosis.

This is usually made by the process of exclusion. Early tuberculous disease, ureteral stricture (which is more common than is usually supposed), calculus of the lower end of the ureter, and the bladder crises of tabes, may give rise to severe bladder symptoms with a clear urine; yet little may be found on cystoscopic examination. The infiltrating form of vesical carcinoma and the caruncle of the urethra may give rise to similar symptoms, but here the lesion is very evident and there should be no difficulty in making a diagnosis. Pyelitis can give rise to marked frequency with few bladder changes; it is excluded by the absence of an appreciable amount of pus. Trigonitis must not be confused with the small contracted bladder that may follow chronic cystitis in women.

Pathology.

I have had no opportunity of performing a post-mortem on any case. Garceau,[2] who examined scrapings from the trigone, found that there was little evidence of inflammation in the stratified epithelium but much subepithelial inflammation. Halle[6] considered that the lesion was a perivascular and perineural fibrosis due to a preceding inflammation.

Treatment.

When the condition has become established, little improvement follows rest, dieting, and the administration of drugs. Irrigations are useless. Dilatation of the urethra with the instillation of 1 to 5 per cent. silver nitrate into the neck of the bladder sometimes does good. Those remedies that do so much good in chronic cystitis have little action in these cases. Suprapubic cystostomy, the formation of a vesico-vaginal fistula, and curettage of the base of the bladder have been performed with little if any benefit. The infiltration of the base of the bladder recommended by Lindemann[7] has given good results, but to carry it out is difficult in women and impossible in men.

Diathermy.—In 1918 I was impressed by the relief that followed the application of diathermy directly to a caruncle of the urethra; in 1919 I carried out the same treatment in cases of trigonitis. There was some improvement, but not a complete cure, as I did not then attach sufficient importance to the lesions present in the urethra. Since this has been realised and remedied, I can claim that immediate and permanent relief follows in practically all cases. Treatment is carried out by means of the cysto-urethroscope of the Brown-Buerger type, a broad electrode being placed on the abdomen and the active electrode, which is insulated except at the tip, is passed down the cystoscope. The current is applied directly to the trigone in lines radiating from the internal meatus. Particular attention should be given to any erosions, fissures in the region of the internal meatus, or lesions of the urethra that may be present. The current should be sufficiently strong to cause the area to which it is applied to take on a whitish appearance. A superficial necrosis is undoubtedly set up; but I have never seen any harm follow, such as infection, persistent ulceration, or stricture formation; this is only to be expected when one considers the results that follow the treatment of vesical tumours by diathermy. Subsequent cystoscopy shows that the congestion has largely disappeared and the trigone has a more normal appearance.

The following cases may be regarded as typical of the series:—

(1) Mrs. B., aged 43, had suffered from frequent and painful micturition since a miscarriage in 1918. Local treatment to the bladder had only aggravated the condition. In September, 1922, she was admitted under the surgical unit, when micturition took place every half-hour during the day and night. There was severe pain most intense at the end of micturition, and there were occasional paroxysms unrelated to micturition. The urine was clear and contained no pus or bacteria. On Nov. 1st diathermy was applied to the trigone and upper part of the urethra. The pain immediately disappeared and the urine could be held for four hours. She was seen in April, 1924, when the urine was clear, frequency was normal, and there was no pain.

(2) Mrs. W., aged 67. Had frequent and painful micturition from 1886 to 1913, when the symptoms subsided. In 1921, when away from home, she found it necessary to retain her urine for a long time, and this was followed by a return of the symptoms. In September, 1923, she was admitted under the surgical unit, when micturition took place every 15 minutes during the day and every hour at night; there was also a griping pain at the neck of the bladder which was relieved by micturition. The urine was clear and contained some red corpuscles, a few pus cells, but no bacteria. Cystoscopy showed intense congestion of the trigone and urethra and a large diverticulum above the right ureter. The application of diathermy was followed by immediate relief of the symptoms. When seen in July, 1924, micturition was normal and free from pain.

(3) Mrs. K., aged 53, was operated upon in July, 1923, for double hydrosalpinx. Retention of urine followed and a catheter was passed for 14 days. Urgent and frequent micturition supervened and there was intense pain at the end of the act. I first saw her in November, 1923, when she was much wasted, and micturition took place every 15 minutes both day and night. On vaginal examination there was a hard mass, evidently malignant, on the left side of the pelvis. The urine contained some red corpuscles, a few pus cells, many epithelial cells, but no bacteria. I thought that the symptoms might be due to pressure on the pelvic nerves or involvement of the bladder, but cystoscopy showed no infiltration of the bladder wall. There was much congestion of the trigone, and near the internal meatus was a small linear ulcer resembling an anal fissure. Immediate improvement followed treatment by diathermy and she had no return of the urinary symptoms up to her death in January, 1924.

(4) J. W., aged 36, a ship's engineer, had suffered from frequent and urgent micturition for six years. There was no history of gonorrhœa, and treatment by the passage of bougies and the instillation of silver nitrate had done no good. The urine contained numerous epithelial cells, a few red blood cells, but no pus cells or threads. The prostate was of the normal consistency and size and its secretion contained no pus. Cystoscopy showed a congestion of the trigone which involved the verumontanum. In July, 1923, diathermy was applied. The symptoms became less severe, and when I heard from him lately, the frequency had disappeared.

The condition has been regarded by some as an inflammation, by others as a neurosis, since the symptoms are quite out of proportion to the lesion present. Incontinence is the prevailing bladder symptom in diseases of the central nervous system, but in multiple sclerosis frequent and painful micturition may be found. In my cases no sign of any nervous disease was present and the Wassermann reaction of both the blood and cerebro-spinal fluid was negative. Psychoses and neuroses of the bladder are by no means uncommon, but in such cases local treatment to the bladder does much harm. Now, when frequent micturition is present, there is interference with sleep and the carrying out of all social duties. The general health soon becomes undermined, and as it is impossible to leave home without first thinking of all possible facilities, it is scarcely to be wondered at that such sufferers become neurotic and introspective. The rapid improvement that follows the relief of the bladder symptoms in cases of trigonitis is proof positive that the neurosis is secondary and not primary.

Sir John Thomson-Walker[8] has pointed out that in the majority of cases of cystitis the inflammation does not affect the whole surface of the bladder mucous membrane, and that the trigone generally bears the brunt. The cystoscopic appearance with the congestion and œdema, and the hypertrophy of the papillæ, bears some resemblance to that seen in chronic cystitis. The bladder, however, is very resistant to bacterial infections, and a persistent cystitis is due either to some infection of the kidneys or to some condition that interferes with the proper evacuation of the urine. Neither is present in trigonitis, which differs very materially from chronic cystitis in that no appreciable amount of pus and no bacteria are found in the urine.

The Present Theory.

The development of the trigone and prostatic urethra in the male and the whole of the urethra in the female differs from that of the rest of the bladder. For the latter is a derivative of the cloaca and its mucous membrane is of entodermal origin, while the former are derived from the lower portion of the Wolffian duct and are of mesodermal origin. There seems to be some difference in their nervous, vascular, and lymphatic supply. That the trigone is the most sensitive part of the bladder can be easily shown in operations under local anæsthesia. Again, when tuberculous disease involves the anterior wall, frequent micturition alone is present, but as soon as it extends on to the trigone there is also much pain. In coli and other infections the pain present is directly proportionate to the degree of involvement of the trigone.

The blood-supply of the bladder is best shown up by cystoscopy. In the normal bladder the blood-supply of the trigone is much greater than that of the rest of the bladder; there is little anastomosis between them and the line of demarcation is very distinct. On the other hand, there is an intimate anastomosis between the veins and arteries of the trigone and those of the neighbouring pelvic organs. For, when bladder symptoms are present in diseases of the latter or arise after pelvic operations and cystitis is excluded by the absence of pus and bacteria, there is a congestion which is confined to the trigone, unless the bladder wall is involved in the inflammation. This congestion is frequently present in the first few months of pregnancy, and, were cystoscopy to be carried out in those who suffer from frequent micturition during menstruation, a similar condition would probably be revealed. A tumour of the pelvis that presses on the pelvic veins may lead to dilatation of the veins over the bladder wall, but more often there is just a congestion of the trigone. Sometimes this congestion is seen in women over 40, which I attribute to a varicosity of the pelvic veins that may develop about the time of the menopause.

Once congestion of the trigone is set up it predisposes to bacterial infection, the bacteria reaching it either from the urine or urethra or by lymphatic extension from the neighbouring viscera. On the other hand, such a congestion may persist after a preceding cystitis has subsided.

It is well known that an active congestion, whether bacterial in origin or not, may give rise to frequent and even painful micturition. But it is difficult to ascertain the symptoms that follow passive congestion. One can, perhaps, best judge from analogy with similar conditions elsewhere. In varicose veins of the leg the symptoms are very variable; occasionally there are severe pains and attacks of cramp, which appear to be most marked when the venules alone are dilated. They are attributed to a perineural fibrosis or to a varicosity of the endoneural veins. It is quite possible that passive congestion in such a sensitive structure as the trigone might give rise to equally severe symptoms. Diathermy would destroy the sensitive nerve fibrils, and the relief that follows can be compared to that seen after an irritable ulcer has been excised or the adjacent nerve divided.

It seems to me that trigonitis can be regarded as due to a congestion of the trigone that follows a preceding cystitis, some inflammation in the neighbouring viscera, or a varicosity of the pelvic veins. This leads to the deposit of small round cells and the formation of fibrous tissue with irritation of the nerve terminals. At any time œdema and ulceration may supervene. Such a hypothesis can explain the absence of pus and bacteria since the lesion is subepithelial; also the immediate improvement that follows the application of diathermy. It corresponds to many points in the ætiology, since such a congestion may follow a previous urinary infection, some inflammation of the pelvic viscera, or a pelvic operation; it may also develop insidiously in association with a pelvic varicocele.

Trigonitis with its marked symptoms and few local changes may be compared to the urethral caruncle, which is regarded by some as an angioma, by others as a local inflammation. But whatever its nature, for its size it is one of the most painful conditions we encounter, and it arises in a mucous membrane which is developed from the same structure as the trigone.

Summary.

1. Trigonitis is a condition associated with severe bladder symptoms but few changes in the urine. 2. Cystoscopy shows congestion limited to the trigone. 3. No pathological changes are detected in the neighbouring pelvic organs. 4. It resists all those remedies that are beneficial in chronic cystitis. 5. The application of diathermy to the trigone produces an immediate improvement in the symptoms.

In conclusion, I wish to express my indebtedness to Prof. A. W. Sheen, director of the Surgical Unit, for the facilities he has placed at my disposal in the carrying out of this work and for many useful suggestions.

THE CHEMICAL COMPOSITION OF BLOOD DURING LABOUR.

BY E. CHRISTINE PILLMAN WILLIAMS, M.B.E., M.B., B.S. LOND.

From the Obstetrical and Gynæcological Unit, Royal Free Hospital (School of Medicine for Women).

IT is becoming more and more recognised that the biochemical examination of the blood during the latter months of pregnancy and during labour is a valuable aid in the early recognition of pathological conditions which may otherwise remain unsuspected. These slight abnormalities unless diagnosed may have serious results, such as nephritis, eclampsia, &c. In many cases the blood of pregnant patients is not examined until they are in labour, or until some clinical abnormality, such as a high blood pressure, is noticed or attracts attention, when on analysis of the blood a raised value for the blood-urea may be found. These values may then be compared with the low blood-urea and non-protein-nitrogen values present in normal pregnancy, as shown by the writer in a previous paper. They are here recapitulated. The average for the whole duration of pregnancy is:—

N.P.N. mg. %.	Urea mg. %.	Diastase.	Ratio.
25·2	19·5	8·8	35·9

The greatest drop takes place, however, during the fifth and sixth months, when the fœtus is growing most rapidly in length. (See Chart.)

Rise in Nitrogen Values During Labour.

In the following notes it is hoped to demonstrate that there is normally a considerable rise in the nitrogen values during labour; in fact, the average is raised to those of the non-pregnant level. This rise is of a noticeably different order from the rise that takes place during the last few months of pregnancy, and takes place very quickly. Unless this rise is taken into account an erroneous idea may be formed as to the patient's condition, both in normal and abnormal cases.

Caldwell and Lyle examined a series of cases and came to the conclusion that there was a low blood-urea and non-protein-nitrogen content of the blood during pregnancy, and that the nitrogen partitions of the maternal blood at the end of labour did not differ much from those found during the last few weeks of pregnancy. Dodds also states that the blood-urea at the end of pregnancy frequently rises to about 40 mg. per cent. without necessarily indicating the likelihood of pathological conditions ensuing. This does not agree with the values found in about 40 cases recently examined by the writer in which the blood-urea has not been found to rise to any such values towards the end of pregnancy.

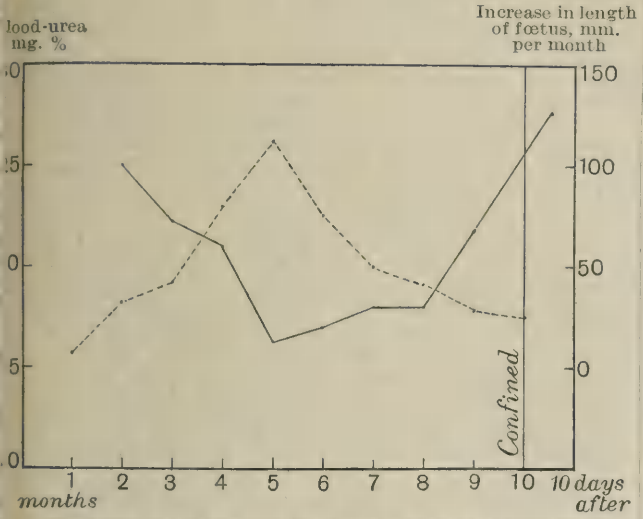

Chart showing the drop in blood-urea which takes place during the fifth and sixth months of pregnancy.

Experimental Results.

About 40 cases have been examined during and after labour, some of whom have also undergone regular blood examinations during pregnancy. The blood-urea, non-protein-nitrogen, and diastase were estimated in these cases, and the average values were found to be as follows :—

	N.P.N.	Urea.	Ratio.
During labour ..	30·4 ..	28·4 ..	43·6
After labour ..	31·5 ..	28·2 ..	41·2

In half the number of the cases the blood taken was during the first stage of labour, in the other half just before delivery, the average of the analyses were as follows :—

	N.P.N.	Urea.	Ratio.
First stage	30·1 ..	28·0 ..	43·3
Second stage ..	30·7 ..	29·1 ..	42·2

Where possible blood examinations were made during labour in cases that had been previously investigated, so that a comparison between the values found during pregnancy and during labour could be made, these figures show an average of :—

	N.P.N.	Urea.	Ratio.	Diastase.
During pregnancy ..	25·9 ..	18·9 ..	34·1 ..	8·1
During labour { First stage ..	30·7 ..	29·2 ..	44·1 ..	—
During labour { Second stage	31·6 ..	28·4 ..	43·2 ..	—
Average of first and second stages ..	31·1 ..	28·9 ..	43·8 ..	—
During puerperium ..	31·2 ..	29·2 ..	41·5 ..	8·8

From these figures it is clear that there is an appreciable rise in the blood-urea and non-protein-nitrogen during labour in normal cases, the average urea content changing from 19·0 mg. per cent. to 28·2 mg. per cent. When a single blood examination, therefore, is made on a patient suspected of some abnormal condition during labour, a due allowance must be made for this normal rise.

The first six cases from the tables for normal cases are given below, and it will be noted that some cases were examined only a few days before labour started ; at those dates the urea content of the blood was still at the low pregnancy level. This quick rise in the blood-urea probably indicates a sudden alteration of metabolism.

The First Six Cases Taken from Table I. Cases Examined During Pregnancy, During Labour, and During Puerperium.

DONATIONS AND BEQUESTS.—Sir Max Leonard Waechter, of Richmond, Surrey, left £5000 each to the Victorian Convalescent Home for Women of Surrey at Bognor, the Children's Convalescent Home, Cambridge House, Bognor, and to Queen Mary's Holiday Fund for Governesses, Petersham, Surrey.—The Committee of the David Lewis Northern Hospital, Liverpool, have accepted an offer by Mr. Clifford Temple of the house and grounds (six acres) known as "Mossley Bank," Aigburth. It will be used as a "Home of Recovery," whither patients will be transferred after they have passed the "acute" stage of hospital treatment. Over £2000 have been subscribed for alterations and maintenance. The home will accommodate 25 patients.—Miss Sarah Margaret Eastwood, Littleover, Derby, left £500 to the Derbyshire Hospital for Sick Children and £1000 to the Leamington Incurables Home.—Mr. Frederick Alfred Badman, of Birmingham, besides other legacies, left £500 each to the Victoria Hospital, Blackpool, the Weston-super-Mare Hospital, the Queen's Hospital, Birmingham, and the Children's Hospital, Ladywood, Birmingham.—At a meeting of the University of Wales on Dec. 11th the Pro-Chancellor acknowledged the grant of £14,000 from the Rockefeller Trust towards the establishment of medical laboratories at the Royal Infirmary, Cardiff, and announced that the University had received £2000 from Mr. Ernest Prosser, of Llanishen, for the endowment of a research fellowship in the tuberculosis department of the National School of Medicine.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

EXHIBITION OF CASES AND SPECIMENS.

A CLINICAL meeting of this section was held on Dec. 12th at the Royal Westminster Ophthalmic Hospital, Sir ARNOLD LAWSON, the President, being in the chair.

Marginal Dystrophy of the Cornea.

Mr. FRANK THOMAS (Swansea) brought two male patients who presented marginal dystrophy of the cornea. He could only find one similar case recorded—namely, by Mr. J. H. Fisher in 1910—on which the late Mr. G. Coats reported pathologically. In these present cases the marginal infiltration had resulted in corneal distortion and the production of hypermetropic astigmatism. Vision in the first case was down to 6/24, though with correcting cylinders it was still about 6/6. The second case illustrated the ultimate condition found in the disorder, for marked peripheral ectasia had resulted, leaving the central area of the cornea distorted, while a high myopia ensued from forward displacement. Vision in this second case was worse than in the other. With correction vision in the right eye was 6/18, in the left 6/36. Mr. Treacher Collins had examined the cases by means of the slit-lamp. Neither of the patients appeared to have suffered discomfort, except for the diminution of vision, which in the first case extended over two years, in the second during ten years. The first, however, reported having had " bloodshot eyes " for 30 years. The older of the patients was sent to the exhibitor by the Miners' Federation under the impression that the man had miners' nystagmus by which he had been incapacitated several years. No trace of this last condition was found. When assured by Mr. Thomas that he had no nystagmus now, the man had the courage to return to his underground work, which he carried out while wearing his glasses, a very rare happening. Each eye was affected in both the cases, pain and discomfort were absent in both, and he did not doubt that both were cases of marginal degenerative change. Only time would show whether the opaque ring in the younger patient would give way under the intra-ocular pressure and also become clear as in the older man. The periphery of the cornea was anæsthetic.

Mr. TREACHER COLLINS agreed that these were both cases of marginal dystrophy of the cornea, though the appearances of the two cases as seen now were strikingly different. The symmetrical character of the condition and the fact that it occurred in coal-miners were in favour of it being dystrophy as against an inflammatory condition. The man with the ectasia showed, when examined with the slit-lamp, the ribbon of light for the cornea definitely incurved on the posterior surface, indicating a thinning in that region. The man with the opacity showed a thinning at the anterior surface of the ribbon of light in the cornea, really a slight grooving of that surface. The thinning in the younger man might in time yield under the normal tension and become an ectasia. Perhaps Mr. Thomas would be able to keep the man under observation to see if that happened. The younger man had many dense opacities in the cornea, and the slit-lamp showed they were in the deep layers of the substantia propria. With regard to treatment, Mr. Fisher's case was treated by excision of a thin piece of the cornea at its margin, and the result was most satisfactory, though it seemed a risky procedure with such a thin cornea. He would not advise operation at present in Mr. Thomas's patient with vision of 6/18.

Gradual Disappearance of Cysts of Iris.

Sir RICHARD CRUISE showed a patient in whom there had been two large cysts of the iris. He showed the patient before the section two years ago, and there was considerable discussion as to what ought to be done, some relating discouraging experiences. Gradually these cysts became smaller, and now but little could be seen of them. The endothelium at the back of the cornea showed where the cysts had been resting. Sir Richard Cruise also described a modified Motais operation which he had successfully performed on a patient whom he showed, and exhibited a case in which he did a modified flap sclerotomy.

Papillœdema in a Myope.

Mr. A. LEVY showed a patient whom he first saw four years ago and who was found to have 8 D. of myopia in each eye. When first seen the vision was about 6/12 in each eye. Three weeks ago the patient came again, still having myopia, and his vision was then only 6/36 ; and now a flaring optic neuritis was visible in both eyes, with a swelling of −1 D. in the optic disc. He showed the case because papillœdema had been said never to occur in a myope.

Leber's Atrophy.

Miss IDA C. MANN showed, for Mr. LESLIE PATON, a case of Leber's atrophy in a man aged 44, four of whose brothers had previously been shown before the section with the same condition. This man had had the condition ten months, and the optic discs were of a dead-white pallor. In the family were six brothers and four sisters, and none of the women showed the change. The oldest brother was affected at 28, the next at 33, the next at 27, the next at 22, and this present patient at 43 years of age. One brother, now aged 34, was so far unaffected. Several members of the family, both male and female, were married, and four sons were among their offspring, none affected.

Mr. RAYNER BATTEN related the case of a family in which three brothers were affected with this disease, and in them the atrophy had been preceded by optic neuritis. — Mr. THOMAS asked whether the cases spoken of showed, on X ray examination, any enlargement of the pituitary fossa.—Miss MANN replied that a skiagram was taken of the skull of this patient, and the report was that there was possibly a little enlargement of the pituitary fossa, but nothing very definite. —Mr. MONTAGUE HINE referred to a definite case of Leber's atrophy in his own practice, in which also X rays failed to disclose any enlargement of the sella turcica.

Pituitary Tumour.

Mr. HINE showed a single man, aged 22, who for two years had been getting stouter. Five months ago he came complaining of headaches and defective vision in the left eye. The corrected vision was, right 6/6, left 6/60. On his next visit two months ago he said the vision of his right eye was becoming worse. Corrected it was now found to be 6/12, the left still being 6/60. The optic disc of the latter was atrophic, and there was some pallor. Bi-temporal hemianopia was not quite complete. Seen by Dr. Gordon Holmes, the latter put him upon 5 gr. of thyroid a day, as a commencement. The skiagram showed the sella turcica enlarged, and much enlargement of dorsum sellæ, such as was seen in pituitary enlargement. The question of operation naturally arose owing to the increasing defect of the right visual acuity and the right upper temporal field. But there was slight improvement in the vision of the left eye and in the field in the left lower temporal quadrant ; also the cessation of the headaches, since the taking of thyroid.

The PRESIDENT said that mere diagnosis of pituitary tumour did not constitute a sufficient reason for operation. He related a case which had all the usual symptoms eight years ago, but no operation was advised. The patient was now managing a hotel and the condition had not progressed in the meantime. When he felt attacks he had been taking pituitrin ; if he neglected to do so he did not feel so well.

Mr. M. S. MAYOU related a different experience in the case of a boy with considerable acromegaly in association with a pituitary tumour. His condition became steadily worse for four years, in spite of his taking thyroid and pituitary extract, and Prof. Harvey Cushing did a decompression operation on him, and the patient had done very well since in respect of vision. The acromegaly continued, but the decompression operation evidently prevented further pressure on the chiasma.

Mr. THOMAS related a case of a large pituitary tumour which he treated with small doses of pituitrin and thyroid, but without benefit. He then increased the dose to 10 gr. thrice daily for a month, and that brought back the lost visual fields, and vision had remained at 6/6. Later the dose had to be increased to 15 ♏ three times a day, and though the patient had some headache he got sufficiently well to resume his work as a postman. But later still he went downhill and died.

Other cases were also shown.

LONDON ASSOCIATION OF MEDICAL WOMEN'S FEDERATION.

A MEETING of this Association was held on Dec. 9th, Miss M. CHADBURN, the President, being in the chair.

Miss E. C. LEWIS read a paper on

Frequency of Micturition in Women—its Ætiology.

She proposed to discuss the symptom from the point of view of its ætiology and from the clinical standpoint, making some attempt at differential diagnosis.* The *causes* could be classified as: (1) Disease of the bladder; (2) irritation of an otherwise healthy bladder; (3) incompatibility of size between the bladder and its contents; (4) a group of nervous diseases, organic and functional; (5) diseases of the kidneys and ureters. In the first group cystitis was an extremely common condition in women, and was likely to be superimposed upon any change in the bladder which might lower its resistance. Prolonged congestion, retention of urine, traumatism, and changes in the bladder wall itself were all causes predisposing to cystitis, and might easily be masked by overlying inflammation; but in every case of cystitis the causative lesion should be looked for and treated. It was easy to see that there must be frequency of micturition in cystitis, but less easy to account for it in other bladder lesions—for instance, with an uninfected diverticulum. As regards neoplasms, the simple papilloma did not cause frequency except when it was bleeding profusely, and then, apparently, because of sudden increase in the amount of fluid in the bladder, since blood in itself was not irritating to the bladder. Miss Lewis had seen cases in which blood was coming down from one of the kidneys in considerable amount, but the bladder itself was normal and there was no frequency. Malignant growths, stones, or foreign bodies always tended to cause frequency. *Irritation of the bladder*, leading to frequency, might be caused by something pressing on it—for instance, an enlarged uterus or an ovarian cyst. A uterus, even of normal size, if very anteflexed or if lying very flat across the pelvis in the antero-posterior direction, might impede the filling of the bladder and cause frequency. This was sometimes accompanied by pain relieved by micturition, unlike the pain of a really unhealthy bladder. *Urethral conditions*, such as prolapse of the urethral mucosa at the external meatus, which occurred typically at the extremes of life, might cause frequency; also a urethrocele, when the clinical picture was that the patient complained of repeated calls to empty the bladder, and that a few drops of urine ran away when she coughed or made any sudden effort. Pelvic inflammations, if acute, probably had an irritating effect on the bladder, while in cases of chronic cervicitis a trigonitis could generally be recognised on cystoscopy. Irritation from within might be caused by some change in the reaction of the urine, or a bacilluria, or an abnormal amount of phosphates or oxalates. Incompatibility of size between the bladder and its contents might be due to a bladder contracted as the result of old inflammation, or to polyuria from whatever cause. *Nervous diseases* might cause motor symptoms of the bladder—hyper-excitability; or sensory—hyperæsthesia. Frequency was very likely in both cases. On the functional side, hysterical and neurasthenic polyuria might be met with. In the last group, frequency due to renal and ureteric conditions, all the inflammations, and several other lesions were included. Most of the conditions, however, came into one or other of the earlier groups. Miss Lewis had been unable to confirm the theory of "reflex" frequency due to kidney disease.

Diagnosis from the Clinical Standpoint.

Patients who complained of frequency only were the most difficult. It was important to ascertain the number of times the patient passed urine by day and by night. One must also know whether the frequency was continuous, or whether it came on in attacks. The estimated quantity of urine passed at each act gave a clue as to whether the bladder really would not hold very much at a time, or whether there was polyuria. Urgency or incontinence should be inquired into; urgency with frequency was said to occur in some of the spinal cord lesions, and incontinence in some of the urethral conditions. In cases of painless frequency, without other symptoms, it was probable that some cause outside the bladder must be looked for. Ordinary routine clinical examination enabled the presence or absence of caruncle, prolapsed urethra, or urethrocele to be determined.

The medical causes of *polyuria* Miss Lewis did not propose to deal with. Surgically, polyuria suggested kidney trouble, such as chronic relapsing pyelitis or pyelonephritis, or in young people early tuberculosis. Frequency accompanied either by pain or by some abnormality of the urine practically always meant a lesion of the urinary tract itself, and in locating the lesion the situation and character of the pain and its timing in relation to micturition were important.

Frequency of Micturition as a Symptom of Systemic Disease.

Dr. IRENE YATES dealt with the clinical aspect of those diseases met with in the practice of a physician in which frequency was a symptom. The commonest of these were: (1) Disorders of the nervous system; (2) inflammatory conditions of the urinary tract; (3) chronic interstitial nephritis; (4) diabetes mellitus. Less commonly met with were diabetes insipidus and so-called diabetes phosphaturia and oxaluria. As to (1), frequency of micturition as a symptom of organic nervous disease was uncommon but might be met with in tabes. In neurasthenics it was a frequent symptom, since their normal stimuli gave rise to abnormal responses. In these patients, when consciousness was abolished, as during sleep, frequency disappeared, hence the importance of obtaining a history of nocturnal frequency. It was also important to ask if the patient was subject to insomnia, since in this case nocturnal frequency would be comparable to diurnal frequency. Inflammatory conditions of the urinary tract had been fully dealt with by Miss Lewis. In chronic interstitial nephritis, frequency when it occurred was due to the polyuria which resulted from the inability of the kidney to excrete non-protein nitrogen in a concentrated form. Dr. Yates discussed the differential diagnosis between frequency due to this cause and to neurasthenia, and then dealt with frequency of micturition as a symptom of diabetes mellitus and of diabetes insipidus. In diabetes insipidus polyuria might be due to a tumour of the pituitary or to irritation of the gland from without (e.g., in syphilitic meningitis). In other cases the polyuria would seem to depend on a polydipsia of nervous origin. Here the volume of fluid excreted was not more than the intake, whereas in the pituitary cases it exceeded it. Probably some of the cases previously reported as diabetes insipidus were cases of chronic interstitial nephritis. In cases of oxaluria without pyuria, frequency of micturition was presumably the result of mechanical irritation of the bladder by calcium oxalate crystals. The treatment was to exclude from the diet articles rich in oxalates, and to give magnesium, since oxalates were more soluble in the presence of magnesium.

---

* The treatment of this condition is dealt with by Miss Lewis in the special article which appears on p. 1351.

Discussion.

Dr. C. Peake drew attention to the fact that often patients suffering from frequency made no complaint, except teachers or children, who found it difficult to get away from their work at short intervals.

The President recalled several cases of tuberculosis of the kidney where frequency was the only symptom for a considerable period.—Mrs. R. Gordon Holmes said that in disseminated sclerosis frequency was often complained of, as well as precipitancy.—Dr. L. M. Jeffries asked whether Miss Lewis had had favourable experience of Victor Bonney's method of operative treatment of a sagging urethra.—Dr. M. A. Blair quoted a case of oscaturia in a patient who had confined her food during Lent to rhubarb.—Dr. M. Dobie had seen cases in which frequency was caused by inflammatory adhesion of uterus or appendix to bladder.—Miss Bannerman described a case in which frequency was attributable to a perinephritis, of which the only symptom was pain under the left shoulder.

Dr. E. M. Guest, Dr. M. Brady, and Dr. Justina Wilson also spoke, and Miss Lewis briefly replied.

LIVERPOOL MEDICAL INSTITUTION.

A pathological meeting of this Institution was held on Dec. 11th, when a discussion on

Cancer

was opened by Dr. James Young (Edinburgh). He presented data in support of the parasitic view and said that it was often urged that the definite effect of chronic irritation in inducing cancer made it unnecessary to predicate the existence of a parasite or any other factor. He suggested that the driving back of the cells to their primitive state by irritation was merely a setting of the stage for the operation of another, an immediate cancerogenic factor. It seemed that in the change of a normal cell to a cancer there were two factors necessary—cell-susceptibility and an immediate agent. Irritation was merely a common way by which cell-susceptibility was accomplished. Dr. Young pointed to the suggestive analogy in plant tumours. Here the dual factors were again apparent. The immediate factor (parasite) could induce neoplasia only when infecting primitive cells—e.g., warty disease in potatoes and crown-gall. Mature areas in the plant ordinarily immune to neoplasia might, however, as Erwin Smith had shown, develop tumours due to the *Bacillus tumefaciens* if the surfaces were previously irritated. Dr. Young described a parasite which he had obtained from all classes of cancer (breast, ovary, uterus, secondary omental masses, secondary masses in glands from glandular and squamous cancer). He showed how, if a piece of cancerous tissue was incubated in any ordinary medium, at the end of 24 hours small perfectly discrete collections of organised elements, varying in size from a minute staining-point and ordinary coccal and bacillary elements up to yeasts, were often found. This striking arrangement was one amongst several observations which at an early stage of his research suggested that in cancer there was concerned an organism of elusive morphology which in the fresh tissue lived within the cells as an inconspicuous form. By means of microphotographs he showed how this phase after death of the cells grew out into the medium as a substance which in its primitive shape resembled an amorphous slime or plasm, but which tended rapidly to arrange itself as globules of greatly differing size, as rods or as hyphal filaments. All forms might be present at the same time. He showed how these various phases were often extremely fleeting and tended in a fluid medium to pass over into coccal or bacillary elements. When the tissue was only half immersed the plasm forms tended to organise into well-staining and well-formed fungal hyphæ. He illustrated all stages in this process and showed how, during the early stages, extremely bizarre forms appeared.

Dr. Young believed that the uniformity of the findings, no matter what class of cancerous growth was employed, indicated that the phenomena underlying malignancy were the same throughout—namely, an infection of cells by an organism (or closely related organisms) living within the cells symbiotically and lashing them into the frenzy of proliferation implied by cancer. This organism in its "saprophytic" phases corresponded to familiar bacteria universally distributed in nature. This accounted for the ease with which cancer might supervene where cell-susceptibility was present—e.g., experimental tar cancer. He referred to the difficulty of producing cancer experimentally with the organism. He believed that the chief obstacle was almost certainly the cell itself, for if the five or six months' preparation found in tar cancer were any index of the time required for the production of cell-susceptibility, it was not surprising that the artificial injection of the organism in a *healthy* animal failed to produce cancer. The exhibition of the organism, no matter how, tended to be followed by blood infection, and the production of a progressive lesion of the pseudo-leukæmic type. Striking confirmation of the specificity of the organism Dr. Young had obtained in the focal reaction in cancer cases treated by vaccines. In this way he had studied over 40 cases. Similar findings had been obtained by A. B. Smith and S. Smith, of Cambridge, and A. Lundie, of Birmingham.

Discussion.

Mr. F. T. Paul considered no line could be drawn between normal tissue growth and cancer; one passed from the embryo, through monsters, teratomata, mixed tissue growths, innocent tumours, recurrent growths to cancer without a break. Every new growth was an erratic counterpart of the tissue in which it originated. These points showed that cancer was closely allied to normal tissue growth and could not very well result from a microbe. He called attention to the exciting and controlling influences over normal tissue growth, giving as an example the growth of a kidney after excision of the opposite organ. There was sufficient evidence to show that cancer only occurred in predisposed individuals. In such he thought the balance between excitation and control was disturbed.

Mr. K. W. Monsarrat said that the parasitic forms described by Dr. Young bore a close resemblance to those which he himself had isolated from cases of breast cancer some years ago, the life cycle of which he had described. He did not hold the view that cancer was invariably due to parasitic invasion. It had been demonstrated that repeated or continuous irritation was capable of turning somatic cells from their orderly course into the cancer type, and he saw no reason to doubt that the long-continued stimulation of a parasitic invasion in an organ like the breast might also bring about the same revolution. He had demonstrated that under certain cultural conditions an organism could be grown from most cases of breast cancer which had a cycle marked by a characteristic pleomorphism. He considered that therapeutic and protective measures, in breast cancer at any rate, might be based on these observations.

Prof. Blair Bell paid a tribute to Dr. Young's work and said: "This work of Dr. Young has not escaped the traditional treatment of all originality. But I can assure Dr. Young, I believe in unison with everyone here to-night, that I sincerely hope he will not only prove his bacteriological thesis to those immediately concerned, but also that he will be able to show that the '*Fungus youngi*' deserves a place alongside the numerous other agents that are believed by some to cause cancer, but which I prefer to regard as producers of a common precancerous condition in the cell."

Prof. J. G. ADAMI said that from his own observations and from his knowledge of Dr. Young and the sincerity of his work he was wholly prepared to accept Dr. Young's observations upon the pleomorphism of the organism discovered by him in cancer of the breast. Those observations coincided strikingly with the earlier observations of Mr. Monsarrat made in the late Sir Rubert Boyce's laboratory 20 years ago. Monsarrat, indeed, had gone further and had evidently, by inoculation of his cultures, induced formative new growths of more than one order in the lower animals. To explain Dr. Young's results as due to imperfect technique was futile and in itself a confession of conservative ignorance, so vast of recent years had become the mass of similar observations by bacteriologists of recognised standing upon bacterial pleomorphism. But while making this acknowledgment, he was far from prepared to associate himself with Dr. Young in regarding this organism as in all probability the essential cause of cancer. Bacteria might be one cause.

Prof. ERNEST GLYNN stated it was generally recognised that bacteria were usually present in malignant growths. But this did not mean necessarily that they preceded the onset of malignancy. On the contrary, they were probably often secondary invaders, entering the growth not only from the surface but by the blood- or lymph-stream. The observations of Ford and others demonstrated that stray bacteria not infrequently enter the organs of healthy individuals. If, perchance, these bacteria reach a malignant growth, they would be more likely to survive and multiply there than in normal tissues.

Prof. C. E. WALKER said that while there was but little doubt that certain micro-organisms were among the causes of cancer, as they provided the necessary degree of prolonged irritation, it was difficult to believe that one particular parasite was the sole cause of cancer.

Prof. J. M. BEATTIE said that the weak point in Dr. Young's case was that he was not able to produce experimental cancer with his organism. Without agreeing with Dr. Young's view, there seemed no reason why his very careful and painstaking work should not be examined carefully without prejudice. No one could deny the possibility of bacteria, not necessarily a specific bacterium, giving rise to irritation and producing cancer just as tar did.

Dr. YOUNG, in replying, thanked the meeting for its generous reception of his work and for the encouragement it had given him.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

A MEETING of this section was held recently in the Royal College of Physicians, Dublin. Dr. L. CASSIDY, the President, occupied the chair.

Dr. BETHEL SOLOMONS read an abstract of a paper written by him and Prof. BRONTE GATENBY on the formation, structure, and physiology of the

Mammalian Corpus Luteum.

After a survey of the historical aspect, the theories as to the formation of the corpus luteum were discussed, and the conclusions arrived at by the essayists pointed indubitably to the fact that the membrana granulosa layer was the responsible factor in formation. The authors had investigated the action of liquor folliculi when given by mouth to humans and to rats. In the former it was tried for the hæmorrhage of puberty, adult life, and the climacteric; also for menopausal symptoms. It was without effect in all these conditions, as the hormone was probably destroyed by the digestive juices. They stated that later it would be tried hypodermically. On rats it had a great effect, and these experiments were intended to run parallel with those of Allen and Doisy, but the rats were fed instead of being injected. Generally speaking, the ovariotomised rats were affected sexually, and control animals which were not given the liquor were not affected: these investigations, however, were not yet complete. Corpus luteum when given by the mouth was useful in the treatment of scanty and absent menstruation. It was a valuable aid in the treatment of sterility, but of little service for menorrhagia and metrorrhagia. It was occasionally helpful in treating dysmenorrhœa. Menopausal symptoms were seldom relieved. It was successful in some cases of vomiting of pregnancy. When administered hypodermically it had cured some cases of severe vomiting and menstrual epilepsy. It was difficult to understand why corpus luteum administered by the mouth or hypodermically should cure amenorrhœa, considering its physiological action: this point required intensive investigation by the physiologist in combination with the gynæcologist. Theoretical explanations were either that the drug stimulated the ovary to action, or that the corpus luteum after administration acted in the same manner as the true corpus luteum. In the same way it was difficult to understand why corpus luteum given all through pregnancy should help in preventing still-births which usually occurred in the last two months. Possibly it produced a healthy corpus luteum which supplied the hormone necessary to the child from the seventh month onwards.

Prof. Gatenby then showed a number of lantern slides illustrating the formation of the corpus luteum in the human, pig, and duck-billed platypus. The theca interna elements in all these animals preserved their integrity until regression of the corpus luteum set in, so that the corpus luteum cells were really of single origin from the membrana granulosa. The corpus luteum of pregnancy was not always larger than that of menstruation. The presence or absence of fatty substances constituted no sort of index as to pregnancy or not. The theories of the action of the liquor folliculi and corpus luteum were discussed.

Discussion.

Prof. H. PRINGLE said that he did not agree with Prof. Gatenby in saying that the luteal cells originated only from the granulosa cells. He believed that the granulosa and interstitial cells originated from the luteal cells. If they had two separate origins, one would expect two specific hormones. There were three separate hormones: (1) The hormone of the interstitial tissue, (2) the hormone of the Graafian follicle, and (3) the hormone of the corpus luteum, and this hormone seemed to antagonise the second hormone. The observations which they had heard that evening from Dr. Solomons and Prof. Gatenby, seemed, he said, to be absolutely incompatible with this hypothesis. One of the most interesting features about the question of the effect of corpus luteum on stimulating ovulation was in cases where ovulation only followed coition. If a rabbit was allowed sterile coition, the corpus luteum following this was practically identical with the corpus luteum following pregnancy, and the corpus luteum persisted practically as long as if the corpus luteum ovum had been implanted. When the abdomen was opened, and the surface of the ovary was follicised, one introduced a factor which might be in every way compatible with sterile coition. It seemed to him that the whole question was still in a very unsatisfactory state, although Prof. Gatenby had added enormously to the knowledge which they had concerning the physiological changes which occurred in the corpus luteum.

Prof. J. M. O'CONNOR referred to the fact that physiology had developed greatly during the last century, and that it was now divided into two parts, one the movements of the body, and the other the development of the body. Attention was now given almost altogether to the mechanical stage of the body. Zoologists dealt with the actual living animals, and gynæcologists could not avoid studying them. The question of internal secretion, however, also had to be considered; he personally had no doubt that internal secretion was a genuine thing, and people had to be alive to its possibilities, but there was always a tendency to scepticism on this subject. He was interested in the statement that there was no interstitial tissue present in the ovary, as he had been led to believe that interstitial tissue was the most important thing that was present in the ovary.

Dr. W. M. CROFTON said that he had given internal secretion by the mouth in some cases and had got physiological results. He had also tried multiglandular preparations in some cases and had found them of great benefit. He wondered why the corpus luteum of pregnancy was so much larger, if the fœtus was to survive in the uterus. He thought that nervous mechanism had an important synchronising effect. If extracts of fresh glands were given before they were frozen, they were much more powerful.

Reply.

Dr. SOLOMONS, in reply, said that some of the speakers had mistaken his views with regard to pluriglandular therapy. Before the menopause he had found mixed gland preparations useless, and never prescribed them. At the menopause he did not order them often, but there were some patients who benefited by a mixed gland tablet which contained suprarenal gland, ovarian substance with corpus luteum, a little pituitary and thyroid extract. He did not consider this was a random shot; on the contrary, it was especially prescribed when the patient had symptoms suggestive of faults in the glands mentioned. While he had spoken of the possibility of trying luteum in the toxæmias of pregnancy, he did not intend to convey any idea that he would cease applying the proved successful methods of the Dublin School of Midwifery.

Exhibition of Specimens.

Dr. G. FITZGIBBON, the Master of the Rotunda, showed specimens from three cases of *Malignant Disease of the Genital Organs*, with direct extensions into the intestinal tract. These three specimens were of interest from the definitely gynæcological origin of the growths and the relatively simple symptoms which suggested uncomplicated gynæcological conditions. The only one in which any trouble outside the genital organs was to be expected was the first, and in it the operation decided upon was for the purpose of dealing with the possible extensions of the disease. The other two cases had serious extensions which called for further abdominal surgery, but the actual nature of the growths was not established for some days after the operations were completed.

The PRESIDENT, in discussing the cases, referred to the rarity of primary cancer of the vagina, and said that he thought Dr. FitzGibbon and Mr. Seton Pringle were to be congratulated on the excellent way in which they had dealt with this case, which must have been an extremely difficult one. Regarding the second case, when a woman of 50 suffered from regular hæmorrhage, and possibly a fibroid, he thought it certainly suggested cancer of the body of the uterus, and he thought that usually on clinical grounds this diagnosis could be made, without doing a primary curettage. The condition found in Dr. FitzGibbon's third case was also a rare one.

Dr. R. J. ROWLETTE said that judging by the slide which he had seen of Dr. FitzGibbon's first case, and also by the history, it was not a case of which one would take at once to be carcinoma, as it might be taken to be a far advanced papilloma. He thought it was more likely that the condition was a secondary implantation of papilloma than that it was primary cancer. During the time he worked in the Rotunda Hospital in 15 years they had only had about three cases of vaginal cancer.

Dr. FITZGIBBON then replied.

Reviews and Notices of Books.

STATUTORY RULES AND ORDERS.

Index to the Statutory Rules and Orders in Force on June 30th, 1924. Showing the Statutory Powers under which They are Made. Tenth edition. Edited by CECIL T. CARR, LL.D. Published by authority. London: H.M. Stationery Office. 1924. Pp. 842. £1 15*s*.

WHATEVER its theoretic disadvantage as a potential menace to civic liberties, the power to deal swiftly with sudden emergencies by means of Orders in Council or other departmental legislation is an indispensable weapon in the armoury of public health. Disease will not wait while Acts of Parliament are prepared and passed. Some ready mechanism for switching special restrictions and precautions on and off is essential, whether it is a question of quarantine provisions against cholera and plague, or of muzzling orders against rabies, or of restricting the movement of cattle in the hope of stamping out foot-and-mouth disease. We have come, too, to expect from the Ministry of Health or some other Government department regulations for the general and permanent protection of the public in matters such as factories and workshops, milk stores, dairies and cowsheds, adulteration of food, water-supply and rivers pollution, crematoria and burial-grounds, notification of diseases, registration of births and deaths, health insurance, vaccination, sale of dangerous drugs, and the like. The new edition of the official Index to Statutory Rules and Orders illustrates the remarkable development of regulation-making as a form of legislation. This well-known index was first published in 1891 under the direction of Mr. Alexander Pulling. The present (tenth) edition is edited by Mr. Cecil T. Carr. The book contains a systematic record of orders with their dates made under Acts of Parliament, arranged under alphabetical headings, showing also whether the power granted has been actually exercised and when. A valuable feature of the volume is the specific information of the Parliamentary powers under which the various rules, regulations, and orders are made. We see, too, the list of Orders in Council under which the Ministry of Health has taken over powers from the Home Office (under the Anatomy Acts, and as to lunacy, mental deficiency, and, in part, factories and workshops) and from the Board of Trade (as to water undertakings), while, on the other hand, the Ministry has surrendered the topic of public libraries to the Board of Education, that of gas undertakings to the Board of Trade, and that of elections to the Home Secretary. There are hundreds of Acts of Parliament which require to be construed in the light of these changes in our central authorities.

The Index, of which the ninth edition showed the position at the end of the year 1919, now speaks nominally to the position on June 30th last, though we notice many entries which bring the story down to the middle of August. While in the interval between the two editions much emergency legislation of war-time origin has disappeared, some of it was evidently too good to throw away. Thus various Defence of the Realm Regulations have taken permanent shape, as the Dangerous Drugs Act and the Firearms Act of 1920, and the Milk and Dairies Act, and the Sale of Tea Act of 1922. There seems to be a war-period Sale of Food Order still partially in force by virtue of the Expiring Laws Continuance Act. The present edition naturally excludes many orders relating to Ireland in matters now within the legislative competence of both the Irish Free State and the Government of Northern Ireland. It is odd, by the way, to find the Home Office in Whitehall responsible for the prevention of epidemics in Belfast.

We commend this publication to local authorities and public libraries, inasmuch as it contains in most convenient alphabetical form not only orders but much valuable information.

PRINCIPLES OF BIOCHEMISTRY.

Second edition. By T. BRAILSFORD ROBERTSON, Ph.D., D.Sc., Professor of Physiology and Biochemistry in the University of Adelaide, South Australia. London: Baillière, Tindall and Cox. 1924. Pp. 1065. 35*s.*

THE text of this volume is divided into six parts. The first deals with foods—proteins, fats, carbohydrates—together with their derivatives. The purely chemical considerations are full but elementary, and other valuable information could have been introduced without unduly increasing the size of the book if some of the philosophical arguments had been replaced by more practical material. A novel feature is the full treatment of mineral metabolism given in this section. Although some of the views expressed are not quite up to date, the description is certainly one of the best in any modern text-book.

One of the best sections of the work is that dealing with the chemistry of the proteins. The author presents the steps leading up to Fischer's synthetic work in a very clear manner. Part I. closes with a chapter on enzymes and one on digestion and absorption, both disappointing in that they are too sketchy; for instance, a large number of mathematical formulæ are given for heat inactivation and similar minor points, but only a page and a half is allotted to the bearing of hydrogen-ion concentration upon enzymes. We were unable to find any reference to pH in the book, and the treatment of ionic dissociation is not in line with modern teaching. Part II. is called "The Properties of Protoplasm." Under this heading are included colloids, osmotic pressure, and the physico-chemical basis of protoplasm. In Part III., dealing with blood and respiration and internal secretions, the work of Folin and his school on blood chemistry is ignored. The section dealing with the internal secretion contains a reasoned summary of the recent advances, with the exception of insulin, to which is allotted merely a few lines. There are no details, or even reference, to the methods of preparation, and no account of the properties or mode of action. This constitutes a rather serious omission. There is a very good account of modern views on oxidation. The remaining parts of the book deal with energy balance, excretion, and the like. An unusual factor is the inclusion of a chapter on memory and sleep.

The volume concludes with a kind of biochemical Nunc Dimittis called "The Outlook," wherein the author in somewhat exalted mood prophesies that "inexhaustible resources of wealth and power" will be laid bare as a result of the further study of biochemistry. Such extravagance is rather damping than encouraging to those who know well the difficulties of applying biochemical research to industrial problems. However, of the enthusiasm of the author for his subject there can be no doubt, and it is not unlikely that this enthusiasm will infect his reader.

PSYCHO-ANALYSIS.

Sigmund Freud, His Personality, His Teaching, and His School. By FRITZ WITTELS. Translated from the German by EDEN and CEDAR PAUL. London: George Allen and Unwin. 1924. Pp. 287. 10*s.* 6*d.*

EVERY writer on psycho-analysis invariably reveals part at least of his own personality, and Wittels here carries the revelation further and lays bare the intimacies of the psycho-analytical movement. Having quarrelled with Freud after five years of coöperation, and spent 14 years in a state of aloofness, he now writes a biography to which Freud himself adds a critical introduction. Opponents will welcome the account of the personal conflicts which led to the secession of Jung and Adler, but noting that the author emphasises the personal element and leaves the reader in the dark as to how far the antagonists are agreed on a basis of observation and how far their divergences are matters of theory. The peculiarities of Jung, Adler, and Stekel as described by Wittels accord with the impressions to be derived from reading their works. Stekel, for instance, is pictured as intuitive, one-sided, insistent and dogmatic, and his analyses are admitted to have no force in confirming the accuracy of psycho-analytical laws. A sympathetic but critical description of Freud presents him as self-contained and impatient of those who would divert him from the path he feels impelled to follow, even if the diversion is towards the goal he is seeking.

It is unfortunate that the author has found it necessary to give yet another exposition of psycho-analysis, an exposition useless to one familiar with the subject and worse than unconvincing to the general reader. The chapter on dream interpretation, for example, invites the most destructive criticism ever levelled at it. He claims more than once that psycho-analysis is a science, but takes no account of its relation to general science or medicine. Perhaps for this narrow outlook the attitude of orthodox medicine is not without blame, but it is none the less regrettable. The uninformed reader would gain no hint of the isolation of psycho-analysis from the world of medicine, an isolation to which Wittels is so reconciled that he seems oblivious of it. He pays tribute to Freud as a great man, but his greatness is measured only by comparison with his adherents or seceders, and the idea of greatness necessitates a wider view. The book is written frankly, and the author admits the limitations and bias resulting from his own temperament. It is interesting, and the translation is well done.

A Neglected Complex and its Relation to Freudian Psychology. By W. R. BOUSFIELD, K.C., F.R.S. London: Kegan Paul. 1924. Pp. 116. 4*s.* 6*d.*

Mr. Bousfield opens with a glowing tribute to the value of the structure of knowledge which Freud has built, and straightway smites him hip and thigh The "neglected complex" consists in a repression of the notions of moral law and moral responsibility, God as the source of moral law, a future life, of free will and telepathy, and in the first chapter we find that anyone predisposed is apt to seize upon the doctrines of the professors of materialism as affording an easy solution of the moral conflict. Freud is selected for attack as the possessor of a complex which in some form or degree is an attribute of many philosophers and scientific men much less in accord with him than the author claims to be. Certainly it is easier to attack Freud than, say, Spinoza, by raising the charge of immoral teaching, a charge supported by a truncated quotation on pages 16 and 80 which is grossly misleading; but this charge has so often been made that it cannot be said to concern a neglected complex. The complex comes into relation with theories of the origin of taboos and primitive beliefs, now the subject of lively controversy amongst ethnologists, though for the author the evidence shows that they correspond to "psychic facts" and were originally implanted in the human mind as germinal ideas capable of evolving with the physical and psychical evolution of men. "Psychic energy," too, presents no difficulties to him; as physical energy comes from the sun so must psychic energy come from an outside source, and "different people absorb supplies of psychic energy in different ways." Many problems would be solved if orthodox science could accept this simple pseudo-materialism. The book may appeal to those who consider any stick good enough to belabour psycho-analysis, but the stick is waved in too wide a circle.

Days Gone By in Central Africa.

Days Gone By; Being some Account of Past Years Chiefly in Central Africa. By J. E. Hine, M.D. Lond., Hon. D.D. Oxon. London: John Murray. 1924. Pp. 313. 16*s*.

Dr. J. E. Hine, like his famous predecessor Arnold de Villa Nova, is a doctor in the three faculties of divinity, law, and physic, and in addition is now the Bishop of Grantham. During some 25 years in Africa he has travelled on foot about 12,500 miles in the course of his episcopal duties, to say nothing of undertaking medical work in addition, and this book is a most interesting, simply written account of his experiences. Missions have their detractors as well as their advocates, but no one can fail to admire the real heroism with which these devoted men battle against climatic difficulties.

Dr. Hine naturally did not have to overcome so many trials as did men like Clapperton, Denham, Mungo Park, Livingstone, or Baker, but occasionally he had a most unpleasant time. His evidently keen sense of humour must have been a priceless asset. He gives an interesting account of his early days at Oxford, and mentions that he was ploughed in "Smalls." He was resident medical officer at the Radcliffe Infirmary, a post which he took after leaving St. George's, and later on worked as assistant to the late Mr. H. P. Symonds, being also an unattached student of the University reading for a pass degree. He mentions that at one time he was examined by three "eminent persons, all of whom I was then attending as a doctor." Dr. Hine was led to seek Holy Orders by hearing an address by Bishop Steere of the U.M.C.A., was ordained in 1886, and went in 1889 to East Africa, a country in which the notorious Dr. Carl Peters had already caused much trouble. He did not stay in Zanzibar long, but was soon sent up to Nyassaland. In due course he was consecrated Bishop of Likoma, later on of Zanzibar, and still later of North Rhodesia. Space fails us to follow the bishop through all his work and journeyings. Suffice it to say that his book is well worth reading. He tells many good stories, one of which we may quote. At Dar es Salaam there lived an Indian trader who had taken as assistant from the Zanzibar Mission School a boy who was not satisfactory. One day Dr. Hine received the following letter from the master:—

> Dear Sir,—I lodge my complaint against this boy Taje . . . I told him to go to the church to which he belonged, which he refused to do. Since that day I have kicked him out of my house. No sooner did this gentleman come here than he began to show signs of his character by assembling a crowd of negresses before my door at midnight, and himself playing a mouth harmonium after I had gone to bed, notwithstanding he knew my wife was ill and confined of twins.

To those advocating the use of music in medicine we commend this story.

Outlines of Organic Chemistry.

By E. J. Holmyard, M.A., F.I.C., Head of the Science Department, Clifton College. London: Edward Arnold and Co. 1924. Pp. 468. 7*s*. 6*d*.

The author is an enthusiastic advocate of the teaching of organic chemistry, which in his opinion is "one of the most delightful branches of learning which it is possible to imagine." The book represents the course which he has given for some years to senior boys and to medical students, and from the somewhat unconventional and at times almost "breezy" style of the book one may conclude that the writer has the gift of appealing to the imagination of a junior audience. The book is divided into five parts, of which the first is devoted to methods of analysis and elementary theory, while the second deals with more advanced theory, including the Lewis-Langmuir electronic theory of valency. The remaining parts follow the conventional lines of division into aliphatic, carbocyclic, and heterocyclic compounds. Much of the matter is, of necessity, dealt with in a sketchy manner. The author's partiality for the historical aspect is betrayed in frequent references, anecdotal and otherwise, to the origin of terms and discoverers of reactions, and in the inclusion of six full-page likenesses of distinguished chemists.

Plant Anatomy.

Fourth edition, revised. By William Chase Stevens, Professor of Botany in the University of Kansas. London: J. and A. Churchill. 1924. With 155 illustrations. Pp. 398. 18*s*.

This is practically the only text-book in English on plant anatomy. As stated in the sub-title, it has been written from the standpoint of the development and functions of the tissues, and this accounts for the inclusion of a section on pedigree hybrids in which the work of Mendel is dealt with at rather greater length than might be expected in a book on anatomy. The work is almost too elementary, but the conventional diagrams certainly help to explain clearly the principles of plant anatomy. The author has included chapters on the use of the microscope, on reagents and processes, and on the detection of adulterations in foods and drugs. It is to be regretted that these sections have not received a drastic revision in this, the fourth, edition of the work, for many of the statements made are inaccurate or misleading, and some of the tests mentioned are either unworkable or obsolete.

JOURNALS.

Military Surgeon. November.—The *Military Surgeon* for November has a number of interesting articles, opening with an account, by Surgeon-General Dr. Bulius, German Army, of the Medical Service of the Third German Army in the Battle of the Marne, 6th–10th September, 1914. Apparently the German medical service had hardly been organised to do duty in an advance so rapid (though their wounded then lacked nothing, as well-supplied medical depôts were captured in that advance); nor were they adequately prepared to function in a retreat, when, for want of motor ambulances, they had to relinquish wounded and medical officers to the rapidly advancing enemy. German stretcher-bearers were surprised, it is noted, to find, on Sept. 8th, that "the wounded French soldiers . . . . apparently feared they would be murdered. Such ideas must have originated with their own troops, for German litter-carriers have never violated their duty."—Lieut.-Commander R. F. Jones, M.C., U.S. Navy, observes that there was much less venereal disease in that navy in 1917 and 1918 than either before or since, which he ascribes to the control of prostitution in the United States during the war. The venereal-rate is far higher for the force abroad (15 per cent.) than at home (7 per cent.), from which he concludes that the control of venereal disease is not possible in the navy without help from the Government through the control of prostitution.—P. P. Jacobs, Ph.D., discusses tuberculosis as a war problem, concluding that there was no spread of tuberculosis in the war, either in the army or the navy. The endeavours to prevent colds, measles, mumps, and similar troubles also reduced fresh tuberculous infections, while good food and fresh air and exercise helped men to resist commencing infections. Health education also played a beneficent rôle. Poisonous gas did not increase liability to tubercle among its victims.—Dr. J. M. Swan, of New York, gives reasons for approving the Dreyer method for the determination of physical fitness, and Captain I. F. Peak, M.C., U.S. Army, in a valuable paper, shows what a help the word-association test may be in determining whether a recruit aviator is really fit to fly.

THE LANCET.

LONDON: SATURDAY, DECEMBER 27, 1924.

LEVANTINE POST-WAR HEALTH PROBLEMS.

British investors recently vied with one another in an endeavour to place some of their capital in the Greek loan, and we may hope that some of them are as interested in its humanitarian as in its financial aspects. Investors are assisting indirectly in a great public health experiment resulting from the displacement of population involved by the late Greco-Turkish war. The Treaty of Lausanne requires members of the Greek Orthodox Church established in Turkey to emigrate to Greece, and Moslems established in Greece to emigrate to Turkey. The total number of refugees so added to the population of Greece amounts to about one and a half million, which is considerably more than 20 per cent. of the total population of that country. Over a million of these refugees, on arrival in Greece, were practically destitute and in urgent need of assistance; during the first months their situation was appalling. The emergency measures hastily improvised by the Greek Government, aided by the invaluable work of American and British Charitable Societies, particularly the American Red Cross, the Near East Relief, the All-British Appeal, and Dr. Nansen's Agency, were successful in relieving immediate distress, but it was obvious that the definite settlement of all suitable refugees in productive work could alone give a permanent solution of the problem. It is believed that the majority of the refugees are of good material, and capable of supporting themselves on the land or in industry if given a reasonable start; it is said that, once supplied with land and a modest equipment, the average refugee "makes good" with remarkable rapidity. The Greek Government has undertaken to provide not less than 500,000 hectares (or about a million and a quarter acres) for settlement purposes. The present external loan provides the means for accomplishing the immense task. It is predicted that great economic results will follow the completion of the scheme of settlement; it is said that the refugees have already transferred to Greece the whole of the rug trade of Asia Minor, that the silk industry has been uprooted and planted afresh in Greece and is becoming firmly established, and that an even more important development will be the production of cereals to an extent which is expected to make the country entirely self-supporting in this respect and in a position to export.

But it must not be forgotten that these economic results will depend very largely on whether the settlers can be kept in reasonably good health in their new surroundings and changed climate and conditions. About 90 per cent. of those who are cultivators are being settled in Macedonia and Western Thrace, which are probably the most malarious regions in Europe. And it is only necessary to recall what happened to the British, French, Bulgarian, and Greek forces who were engaged in the Macedonian area during the war to realise how greatly the prevalence of malaria in an endemic area may be increased by the introduction of numerous new-comers. Evidence that similar disasters can occur in peace time was provided in the summer of 1923, when the arrival of very large numbers of refugees was followed by a malarial epidemic comparable in severity with any preceding outbreak. The refugees who are not cultivators, and therefore must be absorbed in industry, are in some respects worse off than the rural refugees, for many thousands of them are at present lodged in warehouses, improvised dwellings, and temporary huts in Salonika, Athens, and the Piræus under sanitary conditions which leave almost everything to be desired. In Salonika alone during 1923 the number of refugees admitted to hospitals was 15,356, of whom 2072 died. Tuberculosis, malaria, dysentery, enteric fever, and other intestinal diseases prevail among them. It is not known whether any part of the present loan will be allocated to medical and sanitary arrangements in connexion with the settlement of the refugees, but it seems clear that, unless very special attention is given to those matters, the prosperity which has been so glowingly prophesied may be accompanied by great wastage of life and may be long delayed. At present public health organisation in Greece is in a very backward—indeed almost primitive—state, and it is greatly to be hoped that the authorities concerned will seize the present occasion to create a well-trained public health service equipped with means and materials for applying the principles and practice of modern preventive medicine to the many urgent problems which confront them.

In exchange for about one and a quarter million non-Moslems, Turkey receives only about 300,000 Moslems from Greece. The population of Turkey has also been reduced by war service on many fronts and by hostilities on the spot. Depopulation is therefore the great public health problem in Turkey to-day. It is particularly marked on the coast, where the Greeks used to predominate, and in the Meander and Hermus valleys, which were ravaged by war. The pre-war population of the Smyrna district was roughly two and a half millions, but 40 per cent. of the people were non-Moslems. With the exception of a few thousand Jews all these have gone, the result being that the population of the richest part of Turkey cannot now be more than half what it was in 1914. Agriculture and industry are greatly diminished, and in districts where the finest grapes were grown vineyards are running wild. There are no official statistics, but it is said that the prevalence of various epidemic diseases contributes greatly to the alarming reduction of population. Malaria prevails everywhere except in Smyrna itself; tuberculosis has a high incidence and fatality in towns, and venereal diseases are rife in both towns and villages; enteric fever causes a heavy mortality every summer, especially among children. Except in Smyrna and one or two other of the larger towns there are few doctors, and there is everywhere a great lack of drugs. Bread is dear and, although the Anatolian Turk is naturally very hardy, the present conditions of poverty and undernourishment favour the spread and fatality of all forms of disease.

◆

CANCER STATISTICS AND STATISTICIANS.

Cancer statistics offer an inexhaustible attraction to a certain uncritical type of mind. It is not difficult to understand why that should be so. All figures relating to the mortality or to the incidence of cancer are vitiated by fallacies well known to responsible statisticians and all pathologists. The main fallacy arises from the difficulty of correctly diagnosing cancer. Conclusions based on the post-mortem records of the big teaching hospitals in this country, on the continent, and in the United States, disclose an error, due to mistaken diagnosis, amounting to 30 per cent. under the most favourable conditions. The magnitude of this error impresses the pathologist in the post-mortem room; it is only human nature that it should not carry the same weight with clinicians. The pure statistician—that is to say, one who has not had a proper medical training—seems altogether unable to appreciate its significance. The general effect of this fallacy is that the recorded mortality from cancer varies from locality to locality and from country to country with the efficiency of the medical service of the community, and that nowhere does the recorded mortality from cancer reach the actual incidence of the disease. When we compare the incidence of cancer in civilised communities with that in uncivilised communities another fallacy arises. Cancer increases in frequency as age advances. In order to make a comparison it is necessary, therefore, to compare persons of corresponding age. It is of the essence of an uncivilised community that there are no records available which would enable such a comparison to be made. All we know is that in an uncivilised community people die at an earlier age, so that in such a community the total number of cases of cancer, if they were diagnosed with the same degree of accuracy as in a civilised community, must necessarily be less. It is also of the essence of an uncivilised community that there is no efficient medical service.

Appreciation of these statistical fallacies does not require a deep knowledge of statistics. It comes from common-sense deductions following a knowledge of the clinical and pathological features of the disease. But common-sense and knowledge are conspicuous by their absence in the equipment of the enthusiasts who spin their hypotheses from the statistical data on cancer. And it is of such stuff that discoveries are made. We have been assured that cancer is due to an excessive intake of the growth-promoting vitamins and we have been told that vitamin-starvation is an important ætiological factor. We are informed that the negroes of Central Africa are free from cancer. The same freedom is said to be enjoyed by the Eskimaux, and an appeal for funds was made recently by the British Empire Cancer Campaign to send out an expedition to wrest from those clever savages the great secret. Quite recently the discovery has been made that the mortality from cancer is much less among the inmates of lunatic asylums than among the general population. The obvious explanation that a person afflicted with a chronic disease which is undermining his health is more likely to die from the direct or indirect effects of that disease than from another unrelated disease does not seem to have occurred to the authors of this "discovery." Civilised mankind, if it is to be saved from cancer, has, therefore, now the choice either between living like the natives of Central Africa and the Eskimaux—a difficult combination—or to adopt the mode of life of the inmates of a lunatic asylum. The moderation and restraint which the various writers impose upon themselves are alike admirable, for the subject teems with other possibilities. Let us consider a few. No cases of cancer have ever been reported from cannibal tribes. This suggests that either the ingestion of autologous protein confers immunity against cancer or that human flesh contains a protective substance, which, when ingested, confers immunity against cancer, although it does not protect the individual itself in whose body it exists. Again, no cancer has ever been found in the large man-eating carnivora, such as the lion, the tiger, as long as they exist in their normal habitat and have the opportunity of devouring man. But when they are kept in a zoological garden and thus come in contact with civilisation they have been known to develop cancer. This lends further support to the view of the existence of a protective substance in human flesh—perhaps a new vitamin. Common-sense might object that the lack of evidence concerning the occurrence of cancer among cannibals and the large man-eating carnivora is due to the investigators having been eaten. But such an objection may be brushed aside as being due to prejudice and inability to follow new lines of thought.

That, at any rate, is the kind of argument by which Dr. F. L. Hoffman, of New York, a statistician who is not a medical man and who recently has embarked on a Cancer Survey of San Francisco, disposes of the objections to the taking of a cancer census which have been raised by statisticians who, we must guess, are impeded by having a first-hand knowledge of the pathological and clinical aspects of the disease. In the First and Second Quarterly Reports which have just been issued, he writes as follows: "Dr. Bashford, while Director of the Imperial Cancer Research Fund, was decidedly opposed to the taking of a cancer census .... but Dr. Bashford never fully explained his objections, based unquestionably largely upon prejudice and indifference to the results available." The objections of Dr. Bashford are very clearly and explicitly set forth in the Second Scientific Report of the Imperial Cancer Research Fund, and the decision not to hold a census was arrived at by Dr. Bashford in conjunction with the Statistical Subcommittee of the Fund which counted among its members the most distinguished medical statisticians available at the time. In addition to the usual kind of statistical data collected by Dr. Hoffman, he has also sent out questionnaires to every practitioner in San Francisco. It is not stated how many hundreds or perhaps thousands of these forms have been sent out, but there is a statement how many have been returned —25. On the basis of these 25 questionnaires, Dr. Hoffman writes as follows: "The available questionnaires justify some very striking and definite conclusions, emphasising the overshadowing importance of a superabundant meat diet, an excessive amount of sugar, excessive habits of smoking, and exposure to gas and fumes on the part of men in certain occupations. The questionnaires further emphasise the practically universal coexistence of dietary and metabolic disorders, with resulting intestinal complaints. The replies also seem to prove definitely that in many cases there was a coexistent, or a concurrent, rheumatic affection." Has it occurred to Dr. Hoffman that experienced surgeons may see a hundred and more cases of cancer in one year and that so far their clinical experience, extending over thousands of cases of cancer, has failed to establish such simple relationships?

THE BIOCHEMISTRY OF HONEY.

In a letter which appears in our correspondence columns, Dr. G. N. W. Thomas calls attention to the valuable properties of honey in providing a readily absorbable food. The properties of this ubiquitous substance do not appear to be set out in the usual works of reference.[1] The composition of honey is not only very complex, but differs widely according to its source. The water content may vary as much as 12 per cent., the average gravity being 1·46 at 15° C.

---

[1] Information is given in—(1) Abderhalden's Handbuch der biologischen Arbeitsmethoden; Nahrungs- und Genussmittel-Untersuchungen, pp. 977 to 1050. (2) Abderhalden's Biochemisches Handlexikon, vol. ii., p. 179. (3) O. Hänle: Die Chemie des Honigs, Strasbourg, 1892. (4) O. Hänle and A. Scholz: Zeitsch. f. Untersuch. der Nahrungs- u. Genussmittel, 1903, vi., 1027.

An average of 30 analyses of different specimens gave the following percentage result :—

Water	17·2	Malic acid	0·30
Lævulose	39·1	Acetic acid	0·20
Dextrose	34·0	Wax	0·90
Dextrin	0·45	Proteins	1·80
Sucrose	0·40	Mineral salts	0·75
Formic acid	1·10	Undetermined residues	3·80

The mineral salts included Ca, Fe, Mg, PO_4 radicles and a trace of iodine ; among the undetermined residues were resins, gums, pigments, and volatile oils.

Honey is thus seen to consist of a complicated mixture of carbohydrates, of which monosaccharides form by far the greater part. Lævulose and dextrose present, taken together, exceed a hundredfold the dextrin and sucrose. Owing to the relatively low water content, the caloric value of honey is very high ; 1 ounce corresponds to about 100 calories, nearly as much as the same amount of pure cane-sugar. Of the origin of the various constituents little is known. The lævulose, and to a certain extent the dextrose, are derived directly from the nectar and juices of the plant. The origin of the dextrin is still obscure, although it seems to be one of the simpler bodies of its kind with the formula $(C_6H_{10}O_5)_3$, and is said to be readily absorbed from the alimentary canal. The proteins are derived from the pollen of plants. The wax appears to be a specific product of bee metabolism, and the production of honey and wax vary inversely ; as soon as the quantity of wax increases, the supply of honey begins to fall off. The most important constituent of wax is a palmitic ester of myricyl alcohol, $C_{30}H_{61}OH$. Other esters, such as those of cerotic acid and various fatty acids, also occur. The percentage of organic acids, such as malic, acetic, and formic acids, is high and may amount to as much as 2 per cent. in some specimens. With regard to the vitamin-content, it has been stated that honey contains both the fat-soluble and water-soluble principles, and is efficient in warding off deficiency diseases. Various enzymes, such as invertase, are present. The nectar, containing fairly high proportions of sucrose, is digested in the crop of the bee by means of invertases secreted by glands in the head and thoracic region. This digestion, however, is incomplete in the bee itself, and continues after the honey has been deposited in the hive.

On these findings honey constitutes a valuable food, since it contains carbohydrates in a form suitable for direct absorption. The claim is made that honey never gives rise to fermentation in the alimentary canal, since the dextrose and lævulose, being monosaccharides, are absorbed so rapidly that there is no time for bacterial action. This would commend it for infants and children. The fatty acids may have their use in stimulating peristalsis and digestion. Honey, therefore, compares favourably with glucose B.P., which contains only about 35 per cent. of monosaccharide in the form of dextrose and lacks the valuable proteins, fats, and inorganic salts which are present in honey. It would appear, therefore, that Dr. THOMAS'S plea for the extended use of honey has sound biochemical basis.

◆

THE High Commissioner for Southern Rhodesia, Sir Francis Newton, has recently submitted to the London School of Hygiene and Tropical Medicine a proposal which was made originally on the initiative of the Medical Director for Southern Rhodesia, Dr. Andrew Fleming. The school authorities have agreed to send out research workers to investigate diseases common to Rhodesia and to tropical and subtropical South Africa. The Government of Southern Rhodesia for its part has undertaken to make a generous contribution to the school for the purposes of this research work, and to provide laboratory accommodation and equipment. By its recognition of the immense importance of research into the causes of those tropical diseases which now bar the way to the full development of the highlands of Central and Equatorial Africa, the Government of Southern Rhodesia has given a lead to other Colonial Governments.

"Ne quid nimis."

SPLANCHNIC ANALGESIA.

THE merits of splanchnic analgesia for severe operations in the upper abdomen were well shown by papers read before the Section of Anæsthetics of the Royal Society of Medicine on Dec. 12th by Mr. O. S. Hillman and Mr. R. E. Apperly. Following the work of Kappis and of Labat the method has been already fairly extensively employed on the continent, but the papers referred to are the most notable contribution to the subject as yet brought forward in this country. The cases on which these papers were founded numbered 91, and it is noteworthy that they included only one fatality from post-operative chest complications. This and operative shock are the chief dangers in extensive operations on the upper abdomen. Shock is also most decisively decreased by blocking the splanchnic nerves. The method has shown conclusively that afferent impulses do pass from the viscera, along the nerves in the mesentery, and these impulses are effectively blocked by splanchnic injection. Comparing two series of cases of partial gastrectomy the authors showed that without nerve-blocking the mortality was 12·9 per cent. but with it only 3·2 per cent. Again, blood transfusion was needed in 14 cases when there was no nerve block ; only in two cases when this method was employed. The authors are in favour of a light ether anæsthesia during which injections are made to block the anterior abdominal field and then the posterior splanchnic areas. The solution employed is 1 per cent. novocaine without adrenalin. Generally, 25 c.cm. are injected into each splanchnic area. The point of injection is 7 centimetres outside the first lumbar spine. An important point in the technique is to aspirate with the syringe before injecting. If blood is aspirated, showing that the needle has pierced a vessel, no injection is made until the needle has been reintroduced. The fatal effects of injecting novocaine into a vein were well shown by experiments related by Mr. Stanford Cade in the discussion which followed the papers. The authors had at first relied entirely on local injections, preceding these by two injections of morphine and scopolamine. They find that better results are obtained by using a light ether anæsthesia which is preceded only by one injection of morphine and atropine. Post-operative headache and backache have occurred. It is important to avoid raising the shoulders after the injections have been made. Mr. Gordon Taylor, who had operated on many of the cases reported on, spoke enthusiastically of the merits of splanchnic analgesia for severe operations on the upper abdomen. The series included cases in which, in his opinion, operation could not have been attempted without its aid.

PATENT MEDICINES.

Sir Thomas Horder, in an article entitled "Secret Remedies" published in the current issue of the *Cambridge University Medical Society Magazine*, comments on the lack of concerted effort since the war on the part of the press to check the evil of quack nostrums. During the ten years just prior to the war, however, a vigorous effort was made by the medical and the lay press alike to check the abuse, which had grown to huge dimensions, of the manufacture, advertisement, and sale of secret remedies. Following shortly upon this campaign—doubtless in large part due to it—the House of Commons appointed in 1912 a Select Committee "to consider and inquire into the question of the sale of patent and proprietary medicines and appliances, and advertisements relating thereto, and to report what amendments, if any, in the law are necessary or desirable." Unfortunately for the effectiveness of the Committee's work, this report was ordered to be printed on August 4th, 1914, when the greater problem of the quackery of "Kultur" overshadowed all else in the public mind. Like so many other things achieved just prior to the war, Sir Thomas Horder remarks, nothing has been done with regard to the Committee's recommendations so far, and then proceeds to survey the law in relation to secret remedies, which, he said, showed very clearly that in Great Britain the loosest possible control was exercised, far looser than in the majority of foreign countries. None of the Acts of Parliament, nor departments of State, nor statutory bodies controls in any particular, save that of selling poisons without declaring their presence, the vast trade done in patent medicines. The State seems to limit its responsibility to the public to accepting a stamp duty, the scale of which has remained unchanged since 1804. Two significant anomalies may be mentioned: (1) That the Sale of Food and Drugs Act, under which it became an offence to give with any article sold a label falsely describing such article, specifically states that an offence shall not be deemed to be committed "where the drug or food is a proprietary medicine or is the subject of a patent in force"; and (2) that the Indecent Advertisements Act specifically excludes advertisements in newspapers. It was revealed by the Committee's report that no department of State officially concerns itself with the sale and advertisement of secret remedies. The Home Secretary has no powers or duties, and proceedings for fraud against the proprietors or vendors on the ground that they cannot cure the diseases they mention are practically unknown. The dimensions of the trade thus uncontrolled are stupendous. The annual turnover of the proprietor of "Beecham's Pills," selling over a million pills a day, was, Sir Thomas Horder states, about £360,000. The owners of "Mother Siegel's Syrup" paid upwards of £40,000 a year in wages alone. "Wincarnis" spent £50,000 a year in its advertising bureau. As for the profits made, these run often into fabulous sums, as can be seen from the fact that the proprietor of "Dr. Williams's Pink Pills for Pale People"—George Taylor Fulford—left a fortune of £1,111,000. In the face of vested interests of such magnitude it is clear that any interference on the part of the press calls for no small amount of courage and no little confidence in the ultimate good sense of the public.

THE EXPECTATION OF LIFE AFTER A RECOVERY FROM AN EMPYEMA.

There is still some uncertainty, from the life insurance point of view, about the future of persons who have recovered from a non-tuberculous pleural empyema. It is believed in some quarters that these persons are more likely to develop pulmonary tuberculosis than others, and that for this reason they are not acceptable as first-class lives. Some life insurance societies attach the same prognostic significance to a history of non-tuberculous empyema as they do to one of serous pleurisy, and in so doing they bracket the former with one of the most ominous precursors of pulmonary tuberculosis. For, as Allard and Köster have shown, over 42 per cent. of persons with a history of serous pleurisy develop pulmonary tuberculosis within 16 years of the onset of the pleurisy. But are we justified in lumping purulent and serous pleurisy together as far as the expectation of life is concerned? The answer is in the negative, to judge by a paper recently published by Dr. F. Saltzman and Dr. O. Sievers.[1] They investigated in 1922 and 1923 the subsequent fates of the patients treated in the period 1902–1912 for empyema in two surgical hospitals in Helsingfors. They excluded from their investigations the cases terminating fatally in hospital and those which were already of a tuberculous character, confining themselves to the cases in which a complete recovery was effected as far as the empyema was concerned. There were 201 such cases, the subsequent fate of 128 being ascertained from 10 to 20 years after discharge from hospital. In most of these cases the empyema had been acute, presumably metapneumonic. A comparison of the deaths among these patients with the expected death-rate of the total population at the same age showed that the mortality among these ex-empyema patients was about 20 per cent. above normal. This rise in the mortality-rate began about five years after the empyema was contracted and continued during the following five years; ten years after recovery from an empyema it would seem that the expectation of life is practically the same as for the total population. This increased mortality did not seem to depend much, if at all, on tuberculosis; among the 128 patients who were traced, there were 19 who were found to have died, and of these 19 only three were certainly known to have died of tuberculosis. There were, however, five deaths due to unknown causes which in one case may have been tuberculosis, but four tuberculosis deaths out of a total of 19 deaths is not a comparatively high tuberculosis-rate, at any rate in Helsingfors, where, in 1916, 26·5 per cent. of all the deaths were due to tuberculosis. To illuminate the problem from another angle, Dr. Saltzman and Dr. Sievers have investigated the case-records of 3557 patients treated in a sanatorium for pulmonary tuberculosis. In only four of these cases was there a record of an empyema developing before the onset of signs of pulmonary tuberculosis. Paxadoxical as it may seem, the ultimate prognosis, according to the investigations of these Scandinavian authorities, including Allard and Köster, is much worse for a simple serous pleurisy requiring no operative treatment or merely aspiration, than it is for the patient who recovers from a stormy purulent empyema necessitating the intervention of the surgeon.

COLLOIDAL COPPER INJECTIONS IN MALIGNANT DISEASE.

In the course of a presidential address delivered before the Cardiff Medical Society on Nov. 11th, Dr. E. E. Brierley expressed a conviction that many patients who had undergone operations for carcinoma would have had a better chance of survival if a course of colloidal copper injections had been given after operative treatment. He gave notes of patients in whom this treatment appeared to be successful. Two cases of nodular growths in the breast with secondary glands in the axilla, in which operation was refused, were treated by him with intramuscular injections of colloidal copper; the growths and the glands disappeared after a course of injections extending a little over a year. Both patients are still alive and well, ten and seven years after the commencement of the treatment. A patient with a large scirrhus carcinoma of the breast had her breast removed and the axilla cleared in November, 1916. The supraclavicular glands on the same side were found to be enlarged when she was seen by him in February, 1918. Intramuscular injections of colloidal copper were given over a period of eight months; the glands disappeared and the patient is still alive and well. A patient, aged 62, who gave a history of hæmorrhagic vaginal discharge over a period of two years, called him in on account of excessive flooding. Vaginal examination demonstrated the clinical signs of cancer of the cervix. Operation was refused but consent was given for intramuscular injections of colloidal copper. After seven injections the hæmorrhage and discharge had ceased and the patient refused further injections. On examination the cervix was found to be healed and smooth. This patient died away from home nine months later from a "stroke," no return of the vaginal discharge having occurred. A patient who had her breast removed and the axilla cleared out for medullary cancer in August, 1919, dreaded a recurrence; she submitted to a course of colloidal copper injections over a period of three months. The patient has had no recurrence and is alive and well. Another patient had the right breast removed and the axilla cleared for medullary cancer on Feb. 1st, 1920. As there was a small nodular lump in the left breast with enlarged glands in the axilla, and the patient did not wish a second operation, a course of colloidal copper injections were given over a period of three months; the nodular lump and glands disappeared. In September, 1923, the patient returned on account of some enlarged glands in the right supraclavicular region. After a course of colloidal copper injections over a period of four months the glands subsided. The patient is alive at the present time, in excellent health, and no glands can be felt. Two cases of advanced and inoperable carcinoma of the rectum had been treated by him; one improved and put on weight but died in 12 months, the other received no benefit. Dr. Brierley referred also to a case of inoperable cancer of the rectum treated by colloidal copper and selenium, reported by Lionel Norbury in the Proceedings of the Royal Society of Medicine, June, 1923. After treatment for over two years no growth or ulceration could be seen or felt and the general health of the patient was good. Dr. Brierley urged the trial of colloidal copper after operations for cancer and in inoperable cases, emphasising the need of perseverance in the treatment, even if there was no immediate improvement, until the patient was cured or refused further treatment, or until his condition became hopeless.

MEAT POISONING IN PRUSSIA.

A RECENT article[1] by Prof. O. Lentz supplies a good deal of information upon outbreaks of meat poisoning occurring in Prussia between 1907 and 1924 and incidentally throws some sidelights upon the shortage of meat in that country during and after the war. By virtue of an enactment of August, 1905, outbreaks of meat poisoning in Prussia have to be reported by the district medical officers to the appropriate Government department. These reports, although showing some omissions, are available for a survey of the causes and course of these outbreaks. Lentz gives the following table:—

Year.	No. of out-breaks.	Approx. total no. of cases.	Deaths reported.	Year.	No. of out-breaks.	Approx. total no. of cases.	Deaths reported.
1907	10	294	1	1916	7	906	1

* First four months.

While the majority of outbreaks are ascribed to infection with bacilli of the paratyphoid-enteritidis group, eight are credited to *B. proteus* and 24 as examples of botulism. In only one of the latter, however, was *B. botulinus* isolated with certainty, while in two others anaerobes of the type of this organism were present.

The causation of this serious rise in the number of outbreaks is discussed by Lentz. While admittedly some of the outbreaks were associated with the use of food which was perfectly sound, in the majority the meat consumed was derived from animals definitely diseased. In pre-war times such food was very rarely passed and allowed to be eaten, but in consequence of the great shortage of meat during the war and in the after-war period, especially during the years of inflation, more and more necessity-slaughtered meat and meat which eluded inspection altogether was sold for human food. According to Lentz, this assumed very large proportions, and he quotes various reports as bearing out this contention. For example, in the Berlin Kadaververwertungsanstalt during the year 1914, 4,500,000 kilos of animal carcasses and decomposed meat was dealt with, while in 1923 the corresponding amount was only 730,000 kilos. The natural suggestion that during this later period proportionately fewer animals departed this life is countered by the statement that during and after the war, especially during the inflation time in Berlin, a great deal more sausage meat was actually consumed.

Negligent inspection must, in Prof. Lentz's view, bear a large part of the blame for this increase in meat poisoning. In many cases, in spite of offensive septic and other conditions in the animals, the meat had been stamped as fit for food. He gives an instance of a veterinary inspector passing the meat of a cow, in spite of the presence of a much enlarged spleen and small hæmorrhages upon the serous membranes. Two of the slaughtermen concerned subsequently fell ill with anthrax and one died. In spite of repeated reminders from the central authority, bacteriological investigations of suspicious cases are seldom resorted to, and usually the guide utilised is merely the colour and consistency of the flesh. Another instance given is one in which the meat inspector passed meat as fit for use which was definitely suspicious, the only test employed being that he and his family ate a piece of it, his only proviso that it was to be well cooked. This meat caused an outbreak of meat poisoning, due to *B. enteritidis*, involving 62 persons. In only two instances from the many reports is it mentioned that severe offences against the regulations have resulted in the removal of the meat inspector from his office. Legal proceedings against offenders have been quite ineffectual. Lentz presses strongly the need for routine bacteriological examination of all necessity-slaughtered animals before being passed for human consumption. These facts suggest the reflection that the relaxation of a rigid system of meat inspection amongst a people accustomed to be guided by rule is likely to be fraught with greater risk of disaster than a limited inexact system of inspection amongst a community forced to exercise discrimination of their own.

THE VISCOSITY OF PROTOPLASM.

THE physical properties of protoplasm continue to exercise the minds of research workers year by year in the light of new knowledge. Especially important at the present time is the increased study of all histological processes by means of physical methods, witness the whole range of research which has been produced by the introduction of the dark-ground illumination apparatus. The current number of the *British Journal of Experimental Biology* (October, 1924) contains an article by Mr. William Seipiz on a method of studying the elastic properties of protoplasm which throws further light on the viscosity of this substance. Briefly put, the method used consists in suspending a minute particle of a magnetic needle, with the aid of microneedles, in the colloidal protoplasm. By means of an electro-magnet the particle is then attracted until the colloid is stretched to a maximum amount, whilst on release of the magnetic force the particle will return to its original position. The distance over which the particle has travelled in one direction is a measure of the stretching capacity of the substance. The force necessary to produce this stretching is a measure of the elasticity. Of course, a special arrangement of microdissection instrument, microscope and magnet, is necessary for the experiment. The metal particles used were obtained from nickel powder, and the protoplasm selected was the mature unfertilised egg of the sand-dollar, *Echinaraclinius parma*, which is resistant to ill-treatment. As the writer himself points out, the difficulty which confronts the worker on protoplasm is that of deciding with certainty whether the protoplasm is living and normal at the time of observation or not. Numerous safeguards were, therefore, necessary before the author could arrive at the result of $9\,\mu$ as the stretching value of this particular kind of protoplasm, whilst the force applied could only tentatively be estimated.

---

[1] O. Lentz: Ueber Fleischvergiftungen, 1924, Zeitschr. f. Hygiene und Infekt., ciii., Part 2, p. 321.

Nevertheless, these experiments are of value as having a bearing on the general question of the structure of protoplasm. It has been customary for some time to regard protoplasm as a fine emulsion, but emulsions are not elastic, and the author therefore regards this demonstration of the elasticity of protoplasm as a proof that protoplasm is not, from the point of view of its colloidal nature, a fine emulsion.

RADIUM THERAPY.

ANYONE wishing to know what sort of diseases are likely to be benefited by radium treatment is recommended to study the Medical Research Council's Special Report No. 90 on the medical uses of radium, reviewed on p. 1353 of this issue of THE LANCET. A large quantity of radium has been distributed by the Medical Research Council to different research centres, at each of which a definite scheme of investigation has been commenced into the radium treatment of certain malignant and non-malignant tumours. It is only through distribution by a central authority, such as the Medical Research Council, that this very precious substance can be employed where it is most needed. The minute dimension of the applicators makes it difficult to exclude the risk of loss such as that reported last week from the Hull Royal Infirmary. Radium therapy has proved itself of unquestionable value in the treatment of certain tumours; we may instance cancer of the cervix amongst one class and cavernous angiomata in the other. Radium therapy is extremely useful also in the treatment of menorrhagia, as was pointed out in a recent report issued by Dr. R. T. Lewis from University College Hospital. But, on the other hand, to many forms of malignant disease radium hitherto has not brought noteworthy relief. It may be that some types of tumour are naturally more sensitive to the lethal rays than are others, but a consideration of the records supplied by different hospitals, and incorporated in the M.R.C. Report, prompts the thought that we have not yet learnt the most effective way of using this potentially beneficial remedy in certain types of tumour. The difficulties which beset such experimental work as this are great, and time and ripe experience alone can answer many of the questions raised. There is, for example, the established fact that the cancer cell can be definitely killed by radium emanations, though unfortunately this lethal effect is only potent in the immediate neighbourhood of the radium tube. There is also the encouraging discovery that certain types of cancerous growth can be arrested and unpleasant symptoms relieved by irradiation. Perhaps we are only at the beginning of our catalogue of the value of radium to medicine. At any rate, there is sufficient ground for the encouragement of such a systematic research into the uses of radium in the treatment of disease as is being undertaken by the Medical Research Council.

QUEEN CHARLOTTE'S HOSPITAL REPORTS.

AN amended Royal Charter has recently been obtained changing the name of this institution to Queen Charlotte's Maternity Hospital, and this title now appears upon the pages of the 1922 clinical report which has just come into our hands. In this connexion it is worth recording that Dr. G. C. Peachey, in a recent paper read before the Royal Society of Medicine, claimed that he had established the interesting fact that this was the oldest lying-in hospital in the British Isles, dating back to 1739. On account of the war the rather belated 1918 report has only lately been published, and shows that during that year 1649 women were admitted to the 87 beds of the hospital, 69 of which were apportioned to the lying-in ward; whereas in 1922 1820 women were admitted, the beds being reduced to 83, of which 65 were distributed amongst the lying-in wards. In 1918 87 practitioners and students attended the practice of the hospital and 103 pupil midwives trained at the institution passed the examination of the Central Midwives Board; the figures for 1922 were 155 and 144 respectively. The following table gives a comparison of the principal statistics for these two years:—

Year.	Patients delivered.	Patients dis-charged undelivered or admitted for antenatal treatment.	Average length of stay in hospital.	Maternal mortality.	Maternal morbidity (Queen Charlotte's standard).	Rate of		Forceps rate.	Cæsarean section.		
						Still-birth.	Infant mortality.		No. of cases.	Maternal mortality.	Fœtal mortality.
			Days.	%	%	%	%	%		%	%
1918	1653	3	13	0·66	20	4·7	3·4	11·1	37	5·5	16·5
1922	1779	31	12	0·61	11·6	6·4	2·6	7·8	58	3·4	10·3

These clinical reports, as heretofore, give an excellent statistical enumeration of the cases; a number of elaborate tables are included, many of which contain a wealth of detail which only the most exacting could wish for. Particulars of the deaths are set out, with, in some instances, the post-mortem findings; also details of "special cases" are given and we are pleased to see that "cardiac cases" are here shown. An interesting table included in the 1918 report gives a comparison of the figures of the maternal morbidity-rate in the practice of the hospital for the previous eight years, and shows that during that period it was lowest in 1912 and highest in 1917, the figures being 13·4 per cent. and 22 per cent. respectively. The rate in 1918 was 20 per cent., whereas in 1922 there was a drop to 11·6 per cent. An analysis of the cases of pyrexia reveals no satisfactory explanation of this, and influenza cannot be assigned as the cause of the high rate in 1918, as this disease only accounted for just over 1 per cent. of cases. It should be added that the Queen Charlotte standard is extremely high, stricter, in fact, than any in use elsewhere. In comparison with other hospitals the morbidity-rate appears high, but until a uniform standard is adopted throughout the country comparative figures are of no value.

THE TSETSE-FLY.

THE tsetse-flies are of such great economic and ecological importance to Africa that the appearance of a monograph[1] of authority and scope devoted to their study is an event in the annals of tropical medicine. Prof. R. Newstead, F.R.S., and his collaborators have based their description of these insects upon the fine collection assembled at the Liverpool School of Tropical Medicine. Nearly a century has passed since the first two species of tsetse-fly, *Glossina longipalpis* and *G. palpalis*, were described, but now some twenty are recognised and described in this memoir, with one sub-species and five varieties. The genus *Glossina* is confined to Africa, with one exception—*G. tachinoides*, which is found in the Arabian hinterland, separated by over a thousand miles from its most easterly range in the French Sudan. In the descriptive narrative of each species great attention is paid to the morphology of the genital armature in the male; Prof. Newstead regards this as the most important feature on which to base specific distinctions. The bionomics of each species are exhaustively dealt with, and the distribution outlined by means of maps. The work is illustrated by 28 plates, partly after paintings and outline drawings by the author; it is regrettable that the finer shades in coloration which distinguish the various species do not lend themselves readily to reproduction. The coloured photographic records of *G. morsitans* are specially commendable. The student will be grateful for the remarkably complete bibliography of this interesting group of insects. In this monograph the breeding places of various species are illustrated by numerous photographs, thus affording the material for a reasoned attack on the flies at their source. Dr. F. W. Alexander in a leaflet recently issued by the Poplar Public Health Department describes a simple night-trap which may help in the destruction of the tsetse as well as other winged pests. A well-protected night-light or electric light attracts the flies, which then are caught on vertical sheets of ground-glass smeared with some sticky substance. The contrivance, which is easily fixed upon a pole and stood where the pests exist, is certainly worth a trial.

Potts, B.A. Camb.: and a Foreword by Prof. J. W. W. Stephens, M.D. Camb., F.R.S. London: Hodder and Stoughton, Ltd.; Liverpool: University Press of Liverpool, Ltd. 1924. Pp. 268. 20s.

As we go to press we learn with regret of the untimely death of Dr. B. R. G. Russell, of the Imperial Cancer Research Fund.

The Services.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. H. S. Anderson retires on ret. pay.

Maj. M. D. Ahern is seconded for service under the Colonial Office.

ROYAL AIR FORCE.

B. W. Cross is granted a short service commission as a Flying Officer.

DEATHS IN THE SERVICES.

Deputy Surgeon-General Clarence Cooper, who was in the service of the Hon. East India Company in pre-Mutiny days, died at South Norwood Park on Dec. 18th at the age of 94. Born at Brentford on June 28th, 1830, he was the son of George Cooper, F.R.C.S., and after attending schools in England and Germany he entered at King's College, and afterwards studied medicine at Guy's Hospital. Qualifying with the M.R.C.S. Eng. and the L.S.A. in 1852 he almost immediately joined the H.E.I.C.S. as assistant surgeon, and became surgeon major in 1865, and Lieut.-Colonel in 1873, and retired as Deputy Surgeon-General in 1881. An M.D. of St. Andrews and a member of the Royal College of Physicians of London, he served in every branch of the services, and held many civil appointments. In 1855 he was in medical charge of troops in the colony of Labuan, and his services were placed by the Government of India at the disposal of the Colonial Office. He then acted as colonial surgeon, coroner, police magistrate, superintendent of convicts, Colonial Secretary, Judge of High Court, and as a Member of the Legislative Council. After his retirement he joined the Court of Assistants of the Society of Apothecaries of London and became Master of the Society in 1903.

RONTGEN SOCIETY.—A general meeting of this society will be held on Jan. 6th, at 8.15 P.M., in the British Institute of Radiology, 32, Welbeck-street, London, W., when a paper will be read by Dr. N. S. Finzi on Some Developments in Deep Radiotherapy. Members are invited to attend the annual exhibition of scientific apparatus of the Physical Society of London and the Optical Society, which will be held at the Imperial College of Science, Imperial Institute-road, South Kensington, on Jan. 7th and 8th, 1925. Tickets of admission may be obtained on application to the secretaries of the Rontgen Society.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The eleventh meeting of the Royal Commission on National Health Insurance was held at the Home Office on Dec. 18th and 19th, Sir Andrew Duncan in the chair on the 18th and Lord Lawrence of Kingsgate on the 19th. The examination of the representatives of the National Conference of Industrial Assurance Approved Societies, Sir Thomas Neill, Mr. E. F. Spurgeon, and Mr. E. T. Palmer, was continued, the following subjects being dealt with: The methods of government of the industrial societies, the position of deposit contributors, excusal of arrears of contributions due to unemployment, the benefits of women who being insured persons marry, extension of the scope of medical benefit, and provision of dental treatment. Thereafter Mr. Edwin Heather, representing the Independent Order of Oddfellows, Manchester Unity, was examined on the following subjects: The organisation and management of the society, the administration allowance, valuations, and additional benefits.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CII.—TREATMENT OF FREQUENCY OF MICTURITION IN WOMEN.

FREQUENCY of micturition is a common complaint amongst women and may cause considerable distress. In itself it is only a symptom, and thus in a small class of cases only is treatment definitely directed towards it. In the majority of cases its treatment must be that of the lesion to which it is due. I do not propose here to deal with the many acute illnesses in which frequency plays a part, but rather with those in which frequency may, in certain instances, be the only or the predominating symptom.

The causes may be classified in five groups: (1) Organic disease of the bladder; (2) irritation of an otherwise healthy bladder, either by some abnormality in the urine or by some external cause; (3) incompatibility of size between bladder and contents—i.e., a bladder so small that it is unable to deal with the normal output from the kidneys, or a condition of polyuria; (4) organic disease of the central nervous system; and (5) functional nervous conditions.

Organic Disease of the Bladder.

Cases of frequency arising from diseases of the bladder may be divided for our purpose into two groups—those which require purely surgical treatment, and those which require medical treatment.

(*a*) *Conditions Needing Surgical Treatment.—Foreign bodies*, if of small size, may be removed through the urethra after this has been dilated; it must be remembered, however, that the female urethra, although very dilatable, has its limits, and consequently care is necessary. Cases have occurred in which free stretching, prior to the extraction of a foreign body, has resulted in permanent incontinence. It is better to do a suprapubic cystotomy than to risk this.

Malignant Growths.—Where there is any hope of being able to effect a complete removal, the bladder must be opened and the growth removed together with that part of the bladder wall from which it is growing, the viscus being re-formed from what is left. Should the growth be in itself inoperable, the patient's sufferings may be alleviated for a time by opening the bladder above the pubes and burning the growth down to its base with diathermy. The suprapubic fistula may remain, but it sometimes heals up, although a permanent cure is not effected; the distressing symptoms, however, are relieved temporarily. The usual method of dealing with *innocent growths*, unless these are very extensive, is to treat them by diathermy applied through an operating cystoscope. A papilloma, if very small, may be destroyed at one sitting; if larger, repeated treatments are required at intervals of two to three weeks. If a long sitting is expected, with much irrigation, a general anæsthetic may be given, or else sedatives, such as scopolamine and morphine, may be administered beforehand. In both cases the patient is able to return home 48 hours later, and a long convalescence is avoided.

Persistent calls to micturition in young women, particularly when these occur by night as well as by day, often indicate *tuberculosis of the bladder*, secondary to the same disease in one of the kidneys. Such cases demand patient and persistent investigation. When this diagnosis has been established the affected kidney should be removed, unless some definite contra-indication exists.

Diverticula are rare in women. When they occur they lead to frequent calls to empty the bladder, and, in this case, should be resected.

(*b*) *Conditions Requiring Medical Treatment.*—Infection of the bladder with *B. coli* is common among women of all ages, and is highly resistant to treatment when once it has reached the chronic stage. Other organisms are also sometimes responsible. The bacillus may appear primarily in the bladder, or may make its way there via the kidney, and care must be taken to exclude an underlying lesion before proceeding to treatment. Where the infection appears to be confined to the bladder, the patient should avoid chills and over-fatigue, and restrict herself to a non-irritating diet; spiced foods, alcohol, and coffee must be prohibited. Constipation must be treated. It is advisable to give an intestinal antiseptic, such as salol and beta-naphthol aa gr. v., three times a day. The urine should be rendered non-irritating but copious, fluids being taken freely. If the reaction is acid a mixture of pot. cit. gr. xv., sod. bicarb. gr. x., tinct. hyoscyami ♏ xx., inf. buchu ad oz. 1, will be found soothing; it may be necessary to increase the dose of alkalies. On the other hand, an alkaline reaction may usefully be acidified with benzoic acid gr. x. three times daily. Cases untouched by either of these methods may respond to one of the essential oils, such as ol. santali ♏ x., thrice daily. Urinary antiseptics—hexamine gr. xxx. to xlv. in the course of the day, or helmitol, should be exhibited. Local treatment of the bladder, if it can be tolerated, is often helpful. Daily lavage with a tepid solution of pot. perman. 1 in 5000, protargol 1 in 500, or oxycyanide of mercury 1 in 4000 may be followed by leaving in the bladder a few c.cm. of a 10 per cent. solution of gomenol in olive oil. If the infection is a descending one from the kidneys treatment on the above lines should be maintained for some time. Where this is not efficacious, good results may sometimes be obtained by irrigation of the renal pelvis with a 5 or 10 per cent. solution of collargol. Vaccine therapy may be tried, but the results are very variable. A troublesome variety of chronic cystitis is what might be called the *residual tuberculous bladder*—the irritable and often ulcerated bladder which remains after the removal of a tuberculous kidney. General hygienic principles must be adopted, and a diet and treatment prescribed as in chronic simple cystitis, the diet consisting mainly of eggs and milk, fruit, and fresh vegetables. A soothing mixture containing tinct. bellad. ♏ v., tinct. hyoscyami ♏ xx., inf. buchu ad oz. 1, may be tried. Even inf. buchu by itself, though generally prescribed for its diuretic properties only, has a markedly sedative effect on some bladders. Methylene-blue, gr. 1 in a pill three times a day, is sometimes efficacious, and daily instillations of gomenol without lavage give good results if they can be tolerated. If ulcers still persist after prolonged treatment, fulguration sometimes causes them to heal.

Irritation of the Bladder.

(*a*) *External Irritation.*—Among the causes of frequency of micturition under review, external irritation of the bladder is perhaps the one that applies most particularly to women. The lesion may be either pelvic or perineal. In the case of the pelvis, uterine tumours and ovarian cysts cause trouble by preventing the bladder from filling to its normal capacity; the resultant discomfort is one of the indications for surgical intervention. Frequency in the early months of pregnancy calls for examination, as it may indicate a retroverted uterus needing replacement. Chronic inflammatory conditions in the uterine adnexa may cause frequency, although this is by no means an invariable result, but *chronic cervicitis* is a very potent cause of bladder irritability, the viscus being either healthy itself or the seat of a trigonitis with hypertrophic tags and fringes around the internal urethral meatus. These cases will not show any improvement until the cervical condition has been dealt with. The cervix should be treated by appropriate local measures; if a healthy state cannot be established by these means it should be amputated. *Urethral conditions* are very often responsible. The commonest are: a caruncle at the external meatus, best treated by cauterisation; urethrocele, in which satisfactory results are obtained by a buttress operation; and urethral prolapse, which should be excised when giving trouble.

(*b*) *Internal Irritation.*—Irritation of the bladder by some abnormality in its contents, apart from disease of its wall, may be due to a *bacilluria*—usually, but not invariably, of invasion by *B. coli*. This is especially common in women. The treatment is broadly the same as that of the chronic cystitis mentioned above. In some patients the only discoverable peculiarity is a highly acid reaction; these can at once be relieved by the exhibition of large doses of alkalies. Finally, there may be a heavy excretion of oxalates or phosphates. To treat the former, all articles of diet rich in calcium and oxalic acid should be prohibited, and meat, fruit, potatoes, and bread recommended. Doses of dilute mineral acids should be given, and the urine kept acid by the administration of acid sodium phosphate in fairly large doses to dissolve the oxalate of lime. Heavy excretion of phosphates is frequently a manifestation of disordered digestion; this must be inquired into and treated. Rest should be enjoined, and the general condition built up. Care must be taken to keep the urine acid.

Incompatibility of Size between Bladder and its Contents.

For the *sclerosed contracted bladder* very little can be done. If all lesions are healed, and we are only dealing with the sequelæ of old inflammation, attempts may be made to improve matters by graduated distension of the bladder, increasing amounts being injected at successive sittings. But marked success is not likely to be met with. *Polyuria* is itself a symptom, and most of the causes of this complaint—diabetes mellitus and insipidus, Bright's disease, &c.—require an elaborate scheme of treatment which is outside the scope of this paper.

Nervous Affections: Functional and Organic.

Frequency due to disease of the central nervous system also comes into this category. It is often very difficult to combat frequency due to *hysterical and nervous polyuria*. Patients so suffering must be reassured, told that no serious lesion is present, and their confidence gained. A sedative mixture, such as pot. brom. gr. x., tinct. val. ammon. ♏ xv., tinct. hyoscy. ♏ xv., aq. chlorof. ad oz. ½, may be given, and general tonic treatment instituted. In this case also good results may be obtained by graduated fluid distension of the bladder, the patient being persuaded to retain the injection as long as she can hold it. Rest, prescribed in regular hours, also helps to calm the patient.

Conclusion.

Finally, it must once more be emphasised that frequency of micturition is only a symptom. On no account should it be treated for itself alone. Such treatment is only permissible after the fullest investigations have been made, and the possibility of important lesions—such, for instance, as early renal tuberculosis—excluded.

E. Catherine Lewis, M.S. Lond.,
F.R.C.S. Eng.,
Assistant Surgeon, Royal Free Hospital; Assistant
Surgeon and Urologist, South London
Hospital for Women.

Chair of Anatomy in Liverpool.—Dr. William Henry Wood has been appointed to the Derby Chair of Anatomy in the University of Liverpool as from Jan. 1st, 1925. Dr. Wood studied at the University of Manchester, where he took the degree of B.Sc. in zoology and physiology in 1908, M.B. and Ch.B. in 1913, and M.D. in 1923, being awarded a gold medal for his dissertation on the functional significance of the muscular arrangements of the hand. Dr. Wood acted as senior demonstrator in physiology under Prof. W. Stirling, and at the time of appointment was lecturer in anatomy in Manchester under Prof. J. S. B. Stopford. Dr. Wood obtained the rank of captain in the R.A.M.C. during the war.

Special Articles.

MEDICAL USES OF RADIUM.

THE Medical Research Council's Special Report No. 90[1] is a summary of reports received from centres at which during 1923 special investigations have been carried out into the medical use of radium, more particularly in the treatment of malignant disease. The large stock of radium bromide which had been collected for military purposes during the war was entrusted by the Government to the Medical Research Council, who, in the first instance, lent the whole quantity to workers at the Middlesex Hospital for an initial series of experiments. Subsequently the Council distributed the radium among a number of research centres, thereby inaugurating a coördinated inquiry into the medical uses of radium. The present report is the first published statement of the progress and results of this scheme of inquiry, and is based upon the work done in 1923 by the following institutions which received loans of radium from the Medical Research Council: Middlesex Hospital, University College Hospital, St. Bartholomew's Hospital, King's College Hospital, London Hospital, Birmingham General Hospital, Cardiff Royal Infirmary, Aberdeen Royal Infirmary, the Irish Public Health Council, the London Radium Institute, and the Cavendish Laboratory at Cambridge.

The report is divided into three sections, dealing respectively with clinical investigations of malignant disease, clinical investigations of non-malignant conditions, and experimental investigations.

Malignant Disease.

The different varieties of malignant disease to which special consideration was given were cancer of the breast, cancer of the uterus, cancer of the mouth, nasopharynx, larynx and œsophagus, rodent ulcer, and sarcoma and lymphosarcoma. No very definite conclusions can be drawn from the results submitted dealing with radium therapy in cancer of the breast, for it is evident from the different practice of different institutions that no final agreement has yet been reached as to the dosage of radium or how best to employ it. In cancer of the cervix uteri, however, the value and limitations of radium therapy can be more accurately assessed. Thus, the report submitted by University College Hospital concluded by observing that all suitable cases were temporarily improved and symptoms alleviated. "Some cases," it adds, "are benefited to such an extent that they may almost be claimed as clinical cures, having done well for over two years, and, in these, general health is satisfactory and local appearances show no evidence of the old lesion. It is impossible, however, to determine the pathological processes at work in the deep tissues of the pelvis; clinical examination only affords evidence of doubtful value. The intense local fibrosis effectively masks minor evidence of malignant invasion, and progress has to be assessed on the general constitutional state in such cases. Time alone will show to what extent disease has been eradicated and prevented in its spread."

The report received from St. Bartholomew's Hospital draws attention to the fact that the majority of patients suffering from carcinoma of the cervix cease to suffer from hæmorrhage, vaginal discharge, and ulceration after treatment with radium. In many cases life is prolonged, though it would be premature at present to speak of certain cures. Moreover, the preliminary application of radium to operable cases causes the disappearance of fungating growths and ulcers, and minimises the risk of implanting new growths at the time of incising the vaginal wall. The experience gained at St. Bartholomew's Hospital has led to a change of technique, and the research workers intend in the future to treat four different series of patients in different ways in order to obtain information as to the best means of using the radium. There follows an interesting section of the report dealing with tissue changes, both naked-eye and microscopical, after irradiation. In brief, it seems to be confirmed that the main effect of the radium is directly lethal on the cancer cells in the immediate vicinity of the tube, and only to a slight extent stimulatory to the surrounding fibrous tissue.

Dosage.—From the evidence which has been collected the Radiological Committee of the Medical Research Council feel justified in advising the larger dosage employed by some hospitals rather than the smaller dosage of others. The details of the larger dosage method are as follows: 100 mg. inserted in the cervical canal, 50–100 mg. packed round the cervix and left for 30 hours. Two further treatments of 24–30 hours, at intervals of six to eight weeks; or alternatively: 200 mg. in the cervical canal and 130 mg. inserted in the tissues of the cervix and left for 24 hours, the treatment being repeated if necessary.

In cancer of the mouth, nasopharynx, larynx and œsophagus it cannot be said that the prognosis after radium treatment is good. Such growths are notoriously difficult to reach, and the frequent presence of sepsis further complicates the treatment. Still, it is obvious that much remains to be learnt as to the best methods of using radium in these cases; one interesting case, reported fully on pages 18–20 of the report, shows that some patients may be benefited by radium treatment.

A large number of cases of rodent ulcer have been successfully treated by radium, a statement borne out by the Birmingham Hospital experience, which records 62 cases treated. Of these 33 were clinically cured, 19 are still under treatment and improving, 2 have discontinued their treatment, and 4 have been transferred to the X ray department.

The evidence that much benefit has followed the irradiation of sarcoma and lymphosarcoma is not very convincing, and the clinical results show considerable variation. This is hardly surprising, since the growths vary to such a wide extent in character, extent, and histological type. Forty cases were treated during the year, the majority by the surgical introduction of radium into the growth. Among the 33 cases of sarcoma a favourable result was obtained in 18; in the lymphosarcoma cases 5 out of 7 benefited. Histological evidence of the nature of the growth is provided in only a small percentage of the cases under review. The centres have recently been invited to coöperate in a scheme whereby independent pathological examination of sarcoma cases treated by radium is to be made by Prof. E. H. Kettle. The aim of this investigation is to try to correlate the clinical results of radium treatment with the histological character of the growths.

Non-Malignant Conditions.

Twenty-three cases of uterine fibromata were treated by radium at University College Hospital, some with success, others without. Large doses were necessary and sometimes had to be repeated. Dr. R. T. Lewis considers that both ovaries and endometrium undergo considerable changes after radiation, and that a combination of destruction of Graafian follicles, together with atrophy of the endometrium, is the underlying factor in the production of the complete cessation of the periods which may follow radium treatment.

Irradiation has also been employed successfully in the treatment of menorrhagia at the menopause and in the so-called essential menorrhagia of young women who present no sign of pelvic disease. The reports from all the centres speak well of the value of this form of treatment, and there appears to be a considerable degree of uniformity in the dose of radium employed, suggesting that radium therapy in menorrhagia is being set on an established basis.

---

[1] Medical Uses of Radium: Summary of Reports from Research Centres for 1923. London: H.M. Stationery Office. 1924. Pp. 34. 1s.

Radium has received a comprehensive trial in the treatment of angiomata, keloids, and papillomata. For the first of these the report from King's College Hospital observes: "Generally our experience warrants us in expressing the opinion that radium is the treatment 'par excellence' for cavernous angiomata." On the other hand, "port-wine marks" do not respond to radium treatment, while capillary angiomata are perhaps better handled with carbon-dioxide snow. The value of radium treatment for cosmetic purposes is well illustrated in the case reported of an otherwise good-looking baby, whose features were marred by a large, pendulous, cavernous angioma at the end of its nose, giving it an appearance resembling that of "Punch." After treatment with radium practically no disfigurement remained.

Experimental Investigations.

Dr. J. C. Mottram's researches at the Radium Institute on the changes produced on the alimentary tract by radiation are worthy of note. He found that large doses of radium or X rays quickly produced desquamation and necrosis of the intestinal mucosa; the irradiation arrested the secretion of mucus and allowed the bacteria of the colon and cæcum to invade the mucosa. He believes, also, that radiation results in a profound thrombopenia as well as a bacterial invasion of the intestinal mucosa; he considers that the bacterial invasion of the tissues is due to direct action on the intestinal mucosa and not to lowered bacterial resistance following the thrombopenia.

The important investigations of Dr. E. C. Dodds and Dr. J. H. D. Webster into the biochemical changes in patients undergoing radium and X ray treatment were published in The Lancet, 1924, i., 533.

Prof. S. Russ's experiments on the lethal doses of radiation for animal tumours show clearly that the lethal action of radium extends only for a very short distance even when the exposure has been continued for several days.

Conclusion.

The main objective of the schemes of investigation which are being carried out at these different research centres is primarily to define the proper limitations of the uses of radium in the treatment of malignant disease and the best modes of treatment for any given type of disease. Towards this objective notable progress has already been made. Thus in the treatment of cancer of the uterus radium is a remedy of unquestionable value, and experience has pointed the way to assuring the most thorough irradiation and optimum dosage. It appears not only that certain types of tumours are more sensitive to radiation than are others, but that tumours even of the same histological type are not all equally sensitive, and, moreover, the sensitiveness of a given tumour may be affected to an unknown degree by the general or local reactions of the tissues of the host. The question of dosage is, of course, all-important, and the expression of dosage in terms easily understood hardly less so. It is suggested that for some growths it may be useful to express dosage in terms of milligrammes per cubic centimetre of tissue per day. By means of such collective research we may learn what is the optimum dosage of irradiation to give to a particular tumour. At present it is not clear whether in any individual tumour it is better to use a large quantity of radium for a short time or a small quantity for a long time. These and cognate problems are engaging the attention of the various research centres, and the results are being correlated by the Radiology Committee of the Medical Research Council. The personnel of the committee includes Sir Cuthbert S. Wallace (chairman), Dr. Arthur Burrows, Mr. Malcolm Donaldson, Mr. C. Thurstan Holland, Prof. E. H. Kettle, Dr. Robert Knox, and Sir Humphry Rolleston. Its secretary is Prof. Sidney Russ, to whom the committee express indebtedness for the indefatigable labour which he has given to the preparation of this report.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

GRANTS TO HOSPITALS AND CONVALESCENT HOMES.

A meeting of the General Council of King Edward's Hospital Fund for London was held under the Presidency of the Prince of Wales on Dec. 16th, for the purpose of awarding grants to hospitals and convalescent homes.

The Finances of the Fund.

Lord Revelstoke (hon. treasurer) said there would be two amounts to allocate, the ordinary distribution, as recommended by the Distribution Committee, of £235,000, and the further special distribution of £81,000, in aid of hospital extensions and improvements. There was, he said, a serious decrease in the general fund legacies, which were always liable to fluctuations, but, on the other hand, anonymous donations of £7000 and £5000, and a contribution of £15,000 from the British Charities Association, had been received, while other subscriptions and donations had been well maintained.

Sir William Collins, in making the annual statement on behalf of the League of Mercy, said that, although they found increasing difficulty in competing with schemes which offered benefits to their contributors, which the League of Mercy by its constitution could not do, nevertheless, they would by the end of the year be able to hand over the not inconsiderable sum of £14,500, which made the total to the King's Fund, up to the present time, £368,034. The League of Mercy, like the King's Fund, had benefited by the generosity of the British Charities Association, who had entrusted the League with the distribution of £5000 to the extra-metropolitan hospitals. The League had been able to distribute to the provincial hospitals £9760, making a total to the extra-metropolitan hospitals of £64,769. The grand total during the last 25 years was thus £432,802.

Sir Cooper Perry (chairman of the Distribution Committee) presented the report of the Committee on the

Distribution to Hospitals

(including recovery and convalescent branches), which stated that the amount placed at the disposal of the Distribution Committee for allocation amongst hospitals and their recovery and convalescent branches at the present distribution was £233,000, being the same amount as last year. The number of hospitals applying for grants was 118, as against 116 in 1923, applications having been received from the Babies' Hospital (Deptford Fund) and the Brentford Cottage Hospital. The steady improvement in the financial position of the hospitals continued during 1923, when, for the first time since the war, the aggregate income from normal sources showed a surplus over the aggregate expenditure. The surplus was due to exceptional legacies at three hospitals, but, even if these legacies were omitted, the net aggregate deficit for the year was reduced from £175,000 to £20,000. In these circumstances, general attention had been directed during 1924 to the question how far the voluntary hospitals were capable not only of balancing their income and expenditure, but also of extending their work to meet the growing need for hospital treatment.

*List of Awards.**

Major Harold Wernher (hon. secretary) presented the schedule containing the list of awards to hospitals (including recovery and convalescent branches) as follows.

---

* The Distribution Committee desire to draw attention to the fact that it must not be assumed that the reduction or absence of a grant implies dissatisfaction.

	£
Acton Hospital (of which £500 to deficit on extension, in accordance with the scheme submitted to the Fund)	850
All Saints' Hospital	50
Babies' Hospital (Deptford Fund)	25
Baby Clinic Hospital (Kensington)	50
Beckenham Cottage Hospital (of which £1000 to extension, in accordance with the scheme submitted to the Fund)	1,300
Belgrave Hospital for Children (of which £1000 towards the provision of new nurses' accommodation, in accordance with the scheme submitted to the Fund)	2,350
Blackheath and Charlton Hospital (of which £50 towards provision of ward verandahs)	200
Bolingbroke Hospital (of which £1000 to erection of new ward block, in accordance with the scheme submitted to the Fund)	2,250
Brentford Cottage Hospital (to rebuilding and extension on new site, in accordance with scheme to be approved by the Fund)	500
British Hospital for Mothers and Babies, Woolwich	500
Central London Ophthalmic Hospital	700
Central London Throat and Ear Hospital (of which £750 to erection of new out-patient department and permanent wards, in accordance with the scheme submitted to the Fund)	850
Charing Cross Hospital	4,000
Chelsea Hospital for Women (including Convalescent Home at St. Leonards) (of which £500 to new nurses' home, in accordance with the scheme submitted to the Fund)	1,225
Cheyne Hospital for Children (of which £250 towards provision of open-air wards)	450
City of London Hospital for Diseases of the Heart and Lungs (Victoria Park) (including Convalescent Home at Saunderton)	3,575
City of London Maternity Hospital	1,100
Clapham Maternity Hospital	300
Dreadnought Hospital (Seamen's) (including Sanatorium at Liphook, and Convalescent Home at Cudham)	3,000
East End Mothers Lying-in Home	500
East Ham Hospital	100
East London Hospital for Children (including Convalescent Home at Bognor) (of which £500 to reduce debt, and £100 to extension of X ray and pathological departments)	3,800
Elizabeth Garrett Anderson Hospital (including Recovery Branch at Barnet) (of which £1000 to extension, in accordance with scheme to be approved by the Fund)	2,500
Eltham and Mottingham Cottage Hospital	25
Evelina Hospital	850
Finchley Memorial Hospital (of which £100 to deficit on acquisition of adjoining site)	375
Florence Nightingale Hospital for Gentlewomen	250
French Hospital	300
General Lying-in Hospital	600
German Hospital	300
Grosvenor Hospital for Women (of which £500 towards provision of accommodation for resident medical officer and for nurses, in accordance with scheme to be approved by the Fund)	1,000
Guy's Hospital (of which £1500 to improvements)	11,500
Hampstead General and North-West London Hospital (of which £150 to recent improvements)	2,650
Hendon Cottage Hospital (of which £250 to extension of ward block, in accordance with the scheme submitted to the Fund)	550
Hornsey Cottage Hospital (of which £500 to extension, in accordance with the scheme submitted to the Fund)	650
Hospital for Consumption, Brompton (including Sanatorium at Frimley)	1,000
Hospital for Diseases of the Throat (of which £1000 to reconstruction, in accordance with the scheme submitted to the Fund)	1,100
Hospital for Epilepsy and Paralysis (of which £1000 to deficit on extension of out-patient department, in accordance with the scheme submitted to the Fund)	2,750
Hospital for Sick Children (of which £1000 to reduce debt, and £100 to deficit on the provision of fire-escape)	6,100
Hospital for Women (Soho-square)	1,000
Hospital of St. John and St. Elizabeth	750
Infants Hospital (of which £300 to recent improvements)	600
Invalid and Crippled Children's Society Hospital (Canning Town)	450
Italian Hospital	300
Jewish Maternity Home	25
Kensington Dispensary and Children's Hospital (of which £500 to removal and extension, in accordance with scheme to be approved by the Fund)	525
Kensington, Fulham, and Chelsea General Hospital (of which £1000 to rebuilding and extension, in accordance with the scheme submitted to the Fund)	1,050
King Edward Memorial Hospital (Ealing)	500
King's College Hospital	7,500
London Fever Hospital	350
London Homœopathic Hospital	1,750
London Hospital (including Recovery Branch at Reigate)	13,250
London Lock Hospital (of which £600 to maintenance of Harrow-road Hospital, and £100 to maintenance of Dean-street Hospital)	700
London Temperance Hospital (of which £1000 to new nurses' home, in accordance with the scheme submitted to the Fund)	2,500
Maternity Charity and District Nurses' Home (Plaistow) (to the hospital: of which £500 to deficit on rebuilding and extension, in accordance with the scheme submitted to the Fund)	800
Medical Mission of the Good Shepherd, Babies' Home (Hoxton) (to maintenance of babies' ward)	25
Metropolitan Ear, Nose and Throat Hospital	25
Metropolitan Hospital (of which £3000 to new nurses' home, in accordance with the scheme submitted to the Fund)	6,500
Middlesex Hospital (including Convalescent Home at Clacton)	6,400
Middlesex Hospital Cancer Charity	900
Mildmay Memorial Hospital (of which £100 to new operating theatre, in accordance with the scheme submitted to the Fund)	500
Mildmay Mission Hospital (of which £500 to nurses' home, in accordance with the scheme submitted to the Fund)	1,500
Miller General Hospital for South-East London (including Convalescent Home at Bexhill) (of which £2000 to extension, in accordance with the scheme submitted to the Fund)	5,600
Mothers' Hospital of the Salvation Army (of which £500 to extension, in accordance with the scheme submitted to the Fund)	850
Mount Vernon Hospital (Fitzroy-square and Northwood)	1,100
National Hospital for Diseases of the Heart (of which £500 to extension of out-patient department, in accordance with the scheme submitted to the Fund)	800
National Hospital for the Paralysed and Epileptic (including Convalescent Home at Finchley)	4,000
Nelson Hospital (South Wimbledon) (of which £500 to deficit on extension, in accordance with the scheme submitted to the Fund)	1,000
Northcourt Hospital and Home for Sick Children (Hampstead) (in consideration of the fact that curable cases are admitted)	50
North Islington Infant Welfare Wards	50
Norwood and District Cottage Hospital	450
Paddington Green Children's Hospital (including Convalescent Home at Slough)	850
Passmore Edwards Hospital for Wood Green, &c.	50
Poplar Hospital for Accidents (including Convalescent Home at Walton-on-the-Naze) (of which £500 to new nurses' home, in accordance with the scheme submitted to the Fund)	650
Prince of Wales's General Hospital (including Convalescent Home at Nazeing) (of which £500 to deficit on extension, in accordance with the scheme submitted to the Fund)	4,600
Queen Charlotte's Maternity Hospital (of which £500 to reduce debt)	1,800
Queen Mary's Hospital for the East End (including Convalescent Home at Theydon Bois) (of which £1000 to deficit on new maternity home, in accordance with the scheme submitted to the Fund)	4,450
Queen's Hospital for Children (including Convalescent Home at Bexhill) (of which £250 to reduce debt, and £250 to additional nurses' accommodation, in accordance with the scheme submitted to the Fund)	4,500
Royal Dental Hospital of London	250
Royal Eye Hospital	750
Royal Free Hospital (of which £1000 to new nurses' home, in accordance with the scheme submitted to the Fund)	6,000
Royal Hospital (Richmond) (of which £250 to extension, in accordance with the scheme submitted to the Fund)	900
Royal London Ophthalmic Hospital	3,000
Royal National Orthopædic Hospital (including Country Branch at Stanmore)	4,000
Royal Northern Hospital (including Royal Chest Branch in City-road, Recovery Branch at Southgate, and Convalescent Home at Clacton) (of which £1000 to deficit on new nurses' home, in accordance with the scheme submitted to the Fund, and £100 to X ray improvements, in accordance with scheme to be approved)	8,300
Royal Waterloo Hospital for Children and Women (including Convalescent Home at Whippingham) (of which £1000 to extension, in accordance with the scheme submitted to the Fund)	3,350
Royal Westminster Ophthalmic Hospital	650
St. Andrew's Hospital (Dollis Hill) (of which £100 towards provision of lift)	300
St. Bartholomew's Hospital (of which £1000 to new nurses' accommodation)	8,000
St. Columba's Hospital	400
St. George's Hospital (including Recovery and Convalescent Branch at Wimbledon)	7,000
St. John's Hospital (Lewisham) (of which £500 to new nurses' home, in accordance with the scheme submitted to the Fund)	1,200
St. John's Hospital for Diseases of the Skin	300
St. Luke's Hospital for Advanced Cases (of which £250 to deficit on acquisition of new premises, and their adaptation in accordance with the scheme submitted to the Fund)	500
St. Mark's Hospital (of which £250 to extension of out-patient department, in accordance with the scheme submitted to the Fund)	550
St. Mary's Hospital (of which £500 to electric lights and extension of X ray department, in accordance with the scheme submitted to the Fund)	5,500
St. Mary's Hospital for Women and Children (Plaistow) (of which £500 to deficit on new nurses' home, in accordance with the scheme submitted to the Fund)	2,000
St. Monica's Home Hospital (of which £50 to extension of ward lavatories)	175

	£
St. Peter's Hospital for Stone (of which £150 to reduce debt)	440
St. Saviour's Hospital for Ladies of Limited Means (Osnaburgh-street)	100
St. Thomas's Hospital (of which £500 to improvements)	10,500
Samaritan Free Hospital for Women (including Convalescent Home at Amersham) (of which £300 to deficit on installation of central heating)	1,625
Santa Claus Home..	50
South-Eastern Hospital for Children (Sydenham) (of which £500 to deficit on new out-patient department, in accordance with the scheme submitted to the Fund)	1,250
South London Hospital for Women	1,250
Stoke Newington Home Hospital for Women (of which £100 to new operating theatre)	150
Streatham Babies' Hospital	25
University College Hospital (of which £1000 to removal, rebuilding and extension of Royal Ear Hospital branch, in accordance with the scheme submitted to the Fund)	8,500
Victoria Hospital for Children (including Convalescent Home at Broadstairs) (of which £75 towards extra accommodation for cases of enlarged tonsils and adenoids)..	2,550
Walthamstow, Wanstead, and Leyton Children's and General Hospital (of which £1000 to extension, in accordance with the scheme submitted to the Fund)	1,600
West End Hospital for Nervous Diseases	1,500
Western Ophthalmic Hospital	300
West London Hospital	5,000
Westminster Hospital	2,700
Willesden General Hospital (of which £1000 to extension, in accordance with the scheme submitted to the Fund)	2,750
Wimbledon Hospital (of which £350 to deficit on new nurses' home, in accordance with the scheme submitted to the Fund)	700
Winifred House Invalid Children's Convalescent Hospital Home	25
Woolwich and Plumstead Cottage Hospital	25
Total	£233,000

The Earl of Iveagh having seconded the motion, it was carried unanimously. Sir Cooper Perry then presented the report of the Committee on the

Distribution to Convalescent Homes

not attached to particular hospitals.

The sum available for distribution in London is the same in amount as that for last year—namely, £2000—while the number of applications eligible for consideration is 42, as against 40 last year.

Lists of Awards.

Major-General Sir Cecil Lowther presented the schedule containing the list of awards to convalescent homes not attached to particular hospitals as follows:—

	£
All Saints' Convalescent Home, Eastbourne	200
All Saints' Convalescent Home, St. Leonards	50
Baldwin Brown Convalescent Home, Herne Bay ..	25
Beau Site Convalescent Home, Hastings	25
Brentwood Convalescent Home for London Children, Brentwood	25
Brooklands Home (Invalid Children's Aid Association), Worthing	75
Bushey and Bushey Heath Children's Convalescent Home, Bushey	25
Children's Convalescent Home, Beaconsfield	25
Children's Cottage Hospital, Cold Ash, Newbury (in consideration of the fact that convalescent cases are admitted)	25
Children's Home Hospital, Barnet (in consideration of the fact that convalescent cases are admitted) ..	25
Clevedon Sanatorium (Invalid Children's Aid Association), Broadstairs	50
Convalescent Home for Children, Hawkenbury, Tunbridge Wells	25
Convalescent Home for Poor Children, St. Leonards ..	75
Convalescent Police Seaside Home, Hove	75
Edgar Lee Home (Invalid Children's Aid Association), Willesden	50
Florence Emma Home (Invalid Children's Aid Association), Dover	25
Hamilton House (Invalid Children's Aid Association), Seaford	50
Highgate Convalescent Home for Children, Highgate..	50
Home for Invalid Children, Brighton	50
London and Ascot Priory Convalescent Home, Bracknell	100
London and Brighton Female Convalescent Home, Brighton	50
London Homœopathic Convalescent Home, Eastbourne	50
Mental After-Care Association Homes, Fairlight ..	150
Metropolitan Convalescent Institution, Bexhill, Broadstairs (Children) and Walton	100
National Sunday School Union Convalescent Home, Bournemouth	25
St. Andrew's Convalescent Home, Folkestone	75
St. Andrew's Convalescent Hospital, Clewer	25
St. John's Home, Kemp Town (Brighton)	50
St. Luke's Home (Children), Woodley (Reading) (in consideration of the fact that convalescent cases are admitted)	25
St. Mary's Convalescent Home, Birchington	25
St. Mary's Home for Children, Broadstairs (in consideration of the fact that convalescent cases are admitted)	50
St. Michael's Convalescent Home, Westgate	50
Seaside Convalescent Hospital, Seaford..	75
Suffolk Convalescent Home, Felixstowe	50
Sunshine Convalescent Home for Children, Felpham, Bognor	25
Surgical Home for Boys, Banstead (in consideration of the fact that convalescent cases are admitted) ..	50
Tilford Convalescent Home for Children, Farnham ..	50
Victoria Home for Invalid Children, Margate (in consideration of the fact that convalescent cases are admitted)	25
Total	£2000

The adoption of these awards having been seconded by Lord Bearsted, the motion was carried unanimously.

Sir Cooper Perry then presented the report of the Committee on the Special Distribution out of the Wells' legacies.

These to date have been allocated as follows:—

Wells' Legacies Distribution: List of Grants to December, 1924.

Chelsea Hospital for Women.—£1500 towards new nurses' home, releasing the wards now occupied by nurses—viz., half the ward space in the hospital; to be the last £1500 required to enable the home, when ready, to be opened free of debt, on the understanding that the balance is raised by the hospital without drawing on general fund cash or investments.

King's College Hospital.—£16,000 to extinguish the bank debt on the removal of the hospital to South London with accommodation for 388 beds as against 224 on the old site; and £15,000, payable in instalments spread over five years, towards the maintenance of 40 beds, increasing the number open for patients from 276 to 316. Of these 40 beds, 14 were opened on Sept. 1st last and 26 on Nov. 8th. The grants are made on the understanding that an appeal will be issued to extinguish debt on maintenance account and to increase the annual income sufficiently to keep the 40 additional beds open permanently, and, if possible, to open more beds; and on the understanding that 16 of the 40 additional beds are reserved for cases of accident or sudden illness occurring in streets or public places and brought to the hospital by ambulance.

London Temperance Hospital.—£3000 towards new nurses' home, releasing 12 beds in the hospital formerly occupied by nurses; to be the last £3000 required to extinguish the debt on the home, on the understanding that the balance is raised by the hospital by Dec. 31st, 1925, without drawing on general fund cash or investments.

Miller Hospital.—£16,000, of which £10,000 towards the extension from 100 beds to 151 beds, and £6000 towards the new nurses' home; to be the last £10,000 and £6000 required to enable the ward block and nurses' home respectively to be opened free of debt, on the understanding that the balance is raised by the hospital without drawing on general fund cash or investment, and that the building of the ward block is begun by June, 1925, and that, when the ward block is opened, 10 beds are reserved for accident cases.

Prince of Wales's Hospital.—£1000 towards new observation wards with eight beds; to be the last £1000 required to enable the observation wards, when ready, to be opened free of debt, on the understanding that the balance is raised by the hospital without drawing on general fund cash or investments, and that these eight beds are reserved for accident cases.

St. Mary's Hospital for Women and Children, Plaistow.—£1500, payable in instalments over five years, towards the maintenance of six hitherto unopened beds, the number available being thus increased from 60 to 66, on the understanding that the hospital keeps the beds open permanently.

Walthamstow, Wanstead, and Leyton Children's and General Hospital.—£2000 towards extension from 50 beds to 90 beds; on the understanding that the work is begun by May, 1925, and that the balance of the cost is raised by the hospital without drawing on general fund cash or investments, and that, when the ward block is opened, at least five beds are reserved for accident cases.

Woolwich and District War Memorial Hospital.—£25,000 towards the amount required for completing the first stage of the new hospital, thus providing 110 beds, of which it is understood that 14 will be reserved for accident cases; the grant being made to enable tenders to be accepted which would otherwise have lapsed on August 5th last.

Sir James Kingston Fowler having seconded, the report was adopted.

Extension of Operations.

Lord Stuart of Wortley (Chairman of the Management Committee) presented a report of the Committee on the suggested extension of the King's Fund area of operations, and moved recommendations to the effect that (1) as, from Jan. 1st, 1925, the area of operations of King Edward's Hospital Fund be extended from the radius of nine miles from Charing Cross to a radius of 11 miles from St. Paul's; and (2) that approved applications for grants towards capital expenditure or maintenance expenditure from within the area brought in by such extension may be met out of the special distributions of the legacies of the late Mr. and Mrs. Wells.

Lord Marshall having seconded, the recommendations were carried unanimously.

The Prince of Wales then read the following message from His Majesty the King: "I am commanded to convey the congratulations of the King to the President and General Council of King Edward's Hospital Fund that they are again able to distribute £235,000, with the aid of this year's very welcome contribution of £15,000 from the British Charities Association, and the very substantial annual amount for which they are indebted to the League of Mercy. The King is glad to hear that before long the hospitals of London will have 2000 beds more than were open before the war; and that the King's Fund is helping to provide another 300 beds, including 53 for accident cases. His Majesty feels that these satisfactory results of the work of the Fund will tend to strengthen public opinion in favour of the voluntary hospital system."

Remarks by the Prince of Wales.

Continuing, His Royal Highness said that the total distribution would be £316,000, the ordinary distribution being £235,000, the same as last year. The difference, £81,000, represented the first list of grants out of the legacies of the late Mr. and Mrs. Wells, which the Council decided in July last to apply to special purposes, particularly extensions and improvements. Legacies were less than last year, and this would have put the Fund in a difficulty, had it not been for a very welcome contribution of £15,000 from the British Charities Association, for distribution to hospitals in the London area. Income also included £7000 from one anonymous donor, and £5000 from another, as well as a long list of annual subscriptions and donations, headed by H.M. the King, and the annual contribution from the League of Mercy, a never-failing source of strength to the Fund.

The three things that caught the eye in the Distribution Committee's report, said His Royal Highness, were first the enormous improvement in the ordinary finances of the hospitals of London; secondly, the help given to those institutions to enable them to extend their operations; and thirdly, the provision of accident beds. In regard to the last-mentioned, the report of the Ambulance Cases Disposal Committee had been acted on, both by the London County Council Ambulance Service and by the Distribution Committee of the Fund. An increase in accommodation for these cases had been made one of the objects of the Wells' legacies distribution; and out of the 301 additional beds, 53 would be reserved for accidents. Another forward movement by the King's Fund was described in the report of the Management Committee—namely, that the area of operations was to be extended.

The Propaganda Subcommittee, under the chairmanship of Lord Burnham, continued to be very energetic. The following new members had been appointed: Mr. F. J. Whitbread, Sir Richard Terry, Mr. Arthur Powell, K.C., Mr. H. C. King, Mr. MacIver Grierson, and Miss N. Nickalls. The work of the Committee, said the Prince, is partly direct propaganda for the hospitals and the King's Fund, and partly money-raising schemes with propaganda thrown in. The Committee was now arranging for lectures in schools, designed, not to collect money, but to spread amongst the rising generation, of all classes, a knowledge of the work of hospitals, and the debt which the whole community owes to them. Dr. Lazarus Barlow was acting as chairman of a special subcommittee for this purpose. They had at their disposal a panel of expert lecturers, and applications from schools were beginning to come in. Another subcommittee, with Sir Richard Gregory as chairman, had arranged a series of popular scientific lectures in various parts of London for early next year.

Before concluding his speech His Royal Highness mentioned that he proposed to appoint the following three members of committees to be members of the General Council: Dr. Louisa Aldrich-Blake, Mr. Lionel de Rothschild, and Mr. Walter Spencer; and to be a member of the Revenue Committee Mr. W. Pett Ridge, while Sir George Lawson Johnston would take the place of Sir Alan Anderson as chairman of the Revenue Committee.

A vote of thanks to His Royal Highness having been proposed by the Viscount Cave, seconded by Sir Alfred Bower, the Lord Mayor, and carried with acclamation, the Prince briefly replied and the proceedings terminated.

MEDICINE AND THE LAW.

REMOVAL FROM THE PANEL: APPEAL BY A CHEMIST.

A RECENT case in the King's Bench Divisional Court concerning an insurance chemist is of interest also to insurance practitioners in showing the very wide and apparently unrestricted nature of the discretion of the Minister of Health when removing from an insurance committee's list the name of a doctor or a chemist, and in emphasising the extensive judicial powers which are now exercised by Government departments without any effective right of appeal. An insurance chemist was convicted of breaches of the Dangerous Drugs Act; he was fined £100, and in accordance with the customary practice the Home Secretary cancelled his authority to supply dangerous drugs. The Minister of Health thereupon instituted an inquiry under Part VII. of the Medical Benefit Regulations. At this inquiry, be it noted, neither the character of the chemist nor the nature of the offence was considered; the only issue was whether the result of the withdrawal of the chemist's licence to supply dangerous drugs was in itself prejudicial to the efficiency of the insurance service. After considering the report of the inquiry committee, the Minister decided this issue in the affirmative. The Minister offered to permit the chemist to remain on the panel for the limited purpose of supplying appliances and proprietary or other medicines whose supply did not involve a high degree of care—in other words, to be in substantially the same position qua insurance customers as an unqualified person. The chemist declined this offer, and the Minister accordingly removed his name from the insurance committee's list. The chemist then sought by a writ of *certiorari* to cancel the Minister's order. His counsel argued that the Minister's discretion was limited; the National Insurance Act clearly contemplated the inclusion on an insurance committee's list of persons who were not entitled to supply everything, and therefore the Minister could not say that the continuance of a chemist on the list was prejudicial to the efficiency of the service solely on the ground that—owing to the withdrawal of the Home Secretary's licence—the chemist was not legally able to supply dangerous drugs. The Attorney-General, for the Crown, submitted that it was for the Minister to be satisfied whether or not it was prejudicial to the efficiency of the service that the chemist should remain on the panel; the Minister after due inquiry had been so satisfied and the court had no power to intervene. In giving judgment the Lord Chief Justice made it clear that the court had to consider only the question of jurisdiction and not an appeal upon merits. The court were quite satisfied that there was no ground for suggesting that there was an excess of jurisdiction on the part of the Minister. This case once again recognises the claim of the Minister of Health to possess a sole and final discretion in deciding upon the removal from insurance service of doctor or chemist. Provided that an inquiry under the Medical Benefit Regulations has been instituted as a necessary preliminary, it seems clear that there is no effective means of questioning the Minister's decision.

Verdict of Manslaughter against a Medical Man.

At the Central Criminal Court on Dec. 12th Dr. Percy Bateman was found guilty by a jury of manslaughter of a patient, and was sentenced by Mr. Justice Shearman to six months' imprisonment in the second division. The charge was that failure to call in a second medical practitioner and to arrange for an immediate operation, in the circumstances which arose during a confinement, caused or accelerated the woman's death. Dr. Bateman, in giving evidence on his own behalf, said that the nurse who called him in on July 23rd told him that the woman had had pains for two days. On examination he felt the head of the child, gave chloroform, and applied instruments which slipped as it was a transverse presentation. He then performed manual version and delivered the child feet first, afterwards removing the after-birth by putting his hand into the uterus when it came away without the use of force. Some time later, after treating the woman for urgent shock, he discovered that the uterus itself had come away with the after-birth. He decided that the patient was unfit to be removed to hospital, and on each of his twice-daily visits from July 24th to 28th, continued to feel that the patient was never well enough to stand an operation. As the family were worn out he ordered removal to hospital on July 28th. The woman died there two days later. Dr. J. Bright Banister, in giving evidence for the defence, stated that he only knew of two other cases where the uterus had been removed, and in both of them no operation was performed. The woman's chances of life were, in his opinion, as good left where she was as if she had been operated upon. Dr. C. H. Roberts agreed that, as the patient was suffering from acute shock, nothing more could be done beyond leaving her at rest in bed. In summing up, the judge instructed the jury that they could only convict a doctor of causing death by negligence if he had done something which no ordinary skilful doctor should have done. After an absence of an hour and a quarter, the jury brought in a verdict of Guilty.

Tests for Drunkenness.

A man, 35 years of age, was charged at Bow-street police court recently with drunkenness while in charge of his motor-car, and the case against him was dismissed after the magistrate had heard the evidence of Dr. A. S. Woodwark, who had been called in to examine the defendant at his request at the police station, and of Sir James Purves-Stewart. The police surgeon had examined the man at 1.28 A.M., and Dr. Woodwark at 1.48, and a police inspector considered that in the meantime the condition of the accused had changed considerably. Dr. Woodwark allowed the accused to drive him home after the police station formalities had been complied with. He did not consider that the tests applied by the police surgeon were sufficient. Sir James Purves-Stewart, called as an expert for the defence, was of opinion that the examination by the police surgeon was imperfect, and that the tests applied, though satisfactory as far as they went, were elementary and inconclusive. In comment it may be pointed out that frequently at police courts the question whether or not a man was "drunk" at a certain time produces conflicting medical evidence and criticism of the tests applied at the police station. It appears desirable that legal and medical authorities should arrive at a definition of the meaning of the word "drunk" when applied in the police court, and that tests fairly easily applied should be devised whereby "drunkenness" should be established or disproved, if possible, more satisfactorily.

An Impostor.

In The Lancet of Dec. 6th, p. 1216, there was published a warning against an old man named Ferguson, stated to be soliciting alms from medical practitioners by claiming to be a colleague in distress. The warning came from Leeds, and apparently before it had appeared Mr. Ferguson, alias Merrilees, 75 years of age, had been apprehended and sentenced to three months' imprisonment in the second division. This sentence, hardly long enough perhaps to prove an effective deterrent and to protect possible future victims, was brought about through a rather quaintly conceived attempt to extract money from Dr. W. Macargur Scott. Dr. Scott had already given the man £3, believing him to be a brother medical practitioner in distress, when he returned one day and offered to sell him an F.R.C.S. diploma for five guineas, saying that Sir Robert Jones was distributing 200 such "honorary diplomas," and had allowed him (Ferguson) to have one to dispose of. He said to Dr. Scott: "It will look well on your door-plate"; but Dr. Scott, when he had recovered from his astonishment, kept his money in his pocket and communicated with the police. Ferguson's claims to medical qualifications were proved to be unfounded. His last known employment had been that of a lavatory attendant at Manchester.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

FURTHER SITTINGS.

(*Continued from p. 1237.*)

On the resumption of its sittings on Dec. 16th, under the chairmanship of Mr. H. P. Macmillan, K.C., evidence on behalf of the

Association of Poor-law Unions

was tendered by the Rev. P. S. G. Propert (its President), Mr. R. A. Leach, Mr. J. H. Ford (Leeds), and Mr. J. W. Flint.

Mr. Propert declared that in his 30 years' experience the lunacy laws in their relation to the Poor-law had worked smoothly and satisfactorily; there had been an absence of serious complaints. The Chairman commented on the fact that if a person became mentally sick and was received into a Poor-law institution he thereby became, for the time, a pauper, but this did not happen with a person suffering a physical complaint for which he entered a general hospital. Mr. Propert's rejoinder was that Poor-law hospitals were becoming very popular, and he believed the Poor-law stigma was passing away now. He agreed, however, that in this regard mental illness should be approximated to physical illness. Treatment without certification he considered would be a great advantage.

Mr. Leach thought an alleged lunatic should have all the protection given under Section 13 of the Act. The standard of medical skill in Poor-law institutions might not be as high as in mental hospitals, but the standard of the nursing there was as high as anywhere.

Licensed Houses.

Dr. F. H. Edwards, Medical Superintendent, Camberwell House, said licensed houses came into legal existence in 1774, but prior to 1811 no certificates were required in the case of pauper patients detained n them. The only protection these received was that those detaining them might have to answer an action at law for wrongful detention. In 1847 there were 141 licensed houses, with 6629 inmates, 3996 of these being paupers. In 1914 there were only 68 licensed houses, having 3493 inmates (638 paupers). It was chiefly the small licensed houses which were eliminated, and the largest now existing had provision for 672 patients. Licensed houses were not so distributed as to cover the country properly. The licensed house was not carried on for charity but for gain, and some were started by medical men specialising in mental disorder. He described the safeguards enjoyed by the patient in a licensed house, and said that to suppose there was illegal detention would connote a conspiracy between the doctors, the magistrates, and the visiting Commissioners. In the case of his own institution, it was visited by the Lunacy Commissioners eight times a year.

On the following day Sir Cecil Chubb was called. He said he was the proprietor of the Old Manor House, Salisbury, the largest and one of the oldest licensed houses in the country, comprising 19 separate houses which, the witness contended, rendered classification very effective. The patients at present in residence numbered 501, 18 of whom were voluntary boarders, and 150 ex-Service patients. There was a medical superintendent, the staff consisting of four medical men, all of whom were entirely engaged in looking after the medical condition of the patients. The nursing staff numbered 60, excluding ward-men. The probationer commenced at 30*s.* and worked up to £60 and £70 a year; nurses worked eight hours, and sometimes less. Practically all the patients admitted were paying patients, and the average fee charged worked out at £2 14*s.* 9*d.* per week. Many paid £2 2*s.*; some less. With regard to the question whether visitation by the Lunacy Commissioners was apt to become perfunctory, Sir Cecil Chubb said that the patients were given every possible opportunity of speaking to the visiting authority; in fact, on their last visit the Commissioners interviewed 14 patients privately. During the last 14 years he had had no case in regard to which the Commissioners were not satisfied that the patient was properly detained. Answering the Chairman, he said a certain number of the cases to whom leave of absence was granted as an experiment had not returned, but most of them did return. He regarded this granting of leave as a useful provision when convalescence was reached.

The Chairman asked whether when a patient was granted leave his relatives or friends were held responsible for him. He assumed that if the patient returned after such absence he simply resumed his place in the ordinary life of the institution. If after the expiry of the term nothing more was heard of the patient, did the witness then proceed to discharge him?

Sir Cecil Chubb said that 14 days must elapse before any action was taken, and after the expiry of that time steps were taken to discharge the patient. It was not regarded as a duty on the part of the institution to recapture such patient. He added that it was his own opinion that in such a case the onus should be on the friends to ask either for an extension of the leave or the discharge of the patient. On the question of policy as between pauper and private patients, Sir Cecil Chubb thought the rate-aided patient should also have the advantage of two medical certificates. At present it was possible to get a patient into a licensed house on the rate-aided form.

The Chairman: We have been impressed by the divergent methods by which persons reach institutions for the insane. It is undesirable that the methods should be so diverse. I think we are all agreed that there is no reason why one class of person should require two medical certificates and another require one, but we are concerned to consider whether two certificates are necessary in all cases. There are many cases as to which there can be no dubiety, and a possible middle course might be that where any doubt is entertained either by the single doctor or by the judicial authority or justice that either the medical practitioner or the certifying authority should be entitled to call in a second or any number of opinions. Whether that would meet the view it is difficult to say, but it has the drawback that it would leave it to the discretion of the single doctor to decide.

Criticising the preliminaries of the reception of a patient, from the point of view of adequacy of machinery, the witness said that it had happened once or twice that the present method had resulted in persons being brought into the institution who should not have been there. His doctors had refused to receive such patient. There might have been a mistake in diagnosis; for instance, a country practitioner might confuse a case of delirium tremens with one of insanity. He maintained that the person signing the reception order should personally see the patient. As regards the urgency order it had been laid down under Section 11 that it should be granted where it was expedient in the public interest that the patient should be detained. He thought there should be a provisional order of short duration, say of three days, which could be extended. He agreed that the existing code adequately safeguarded the patient in the matter of discharge. As to the rate of recovery at the Old Manor House, in 1923 the total percentage of recoveries [illegible] compared with direct admissions—eliminating transfers—had been 31·64. The average rate of discharge from 1914–23 had been 37 per cent. There were, of course, recurring cases. As to the reception of voluntary patients, he did not like receiving them, for the reason that the voluntary boarder was of one of two categories. There might be the incipient case of insanity which should be treated on different lines at special institutions. He objected to receiving voluntary boarders and later having them certified. Since the Harnett case there had been many more applications from would-be voluntary boarders than formerly, simply owing to the great reluctance on the part of doctors to certify. Very recently a medical man declared to him that he would not certify a person for £20,000. Replying to a question from the Chairman as to whether, on acccount of this reluctance, cases were reaching the institution under the guise of voluntary patients who, normally, would come as certified ones, the witness said that was so. He promised to furnish the Commission with a return giving the number of voluntary patients in his institution from January, 1923, to the present date.

Sir Humphry Rolleston asked whether the reluctance of doctors to certify might not act against the general operation of the law by making it difficult to get people under any kind of control before they had gone so far that curative measures would not have a proper chance.

Sir Cecil Chubb replied that this was a question for the doctors, though he thought there was a tendency in that direction, judging from the number of applications received from voluntary boarders.

Dr. Frank Fawcett was the next witness. He is a Medical Visitor to licensed houses, appointed under Section 177 of the Act, for East Sussex. In this capacity his experience had extended to 33 years. He described the procedure at his visitations four times a year. Special attention was paid to the recent admissions, and all papers relative to them were gone through and the patients seen. At the visitations every opportunity was given to patients to privately interview the visitors. If patients were out on leave, a full report about them was made. Complaints were almost solely concerned with continued detention, but they were patiently listened to. They were given to understand that visitors were a means of communication with the outside world. He had never felt that a patient seen by him had been fit for discharge, unless he were so far recovered that discharge was imminent. He did not remember an instance in which a patient, at the first interview, alleged he ought not to have been detained.

Mr. H. Snell, M.P., questioned the witness as to the actual facilities patients enjoyed to make a real complaint privately, especially as five or six visitors were together going round. The witness said encouragement was given to patients to say anything which was on their minds, and this was not difficult as the majority of the patients were seen in their rooms, not in a large place where there were a number of patients. Answering the Chairman, who asked whether there was any risk that patients might be deterred from making complaints because of possible punishment afterwards, or being made to feel that it might be the worse for them afterwards, he replied that he felt sure that in the three institutions which came into his visitations nothing of the kind occurred.

The next witness was Sir James Barr, also a medical visitor, appointed under Section 177 of the Act, in the Liverpool area, to Tue Brook Asylum. He explained that he had performed this function 40 years. He considered that the provisions of the Act were efficacious as a safeguard against the undue detention of patients. The medical proprietor had always been anxious for the recovery of his patients, and he took every suggestion made to him in regard to both treatment and administration. He had not heard a complaint for years, even about diet. Complaints were more common and emphatic from undoubted cases of insanity than from those on the way to recovery, and the only complaints he had were from the first of these, and mostly took the form of objecting to their detention. There might be a difference of opinion sometimes as to when a recovering patient might be let out. There were only about six voluntary boarders in the institution, but he thought this class should be encouraged. If people were to understand clearly that the benefits of an institution could be had without certification probably cases would come at an earlier and more curable stage of their illness. Most of the cases coming in under the voluntary guise he regarded as not properly belonging to that class; they were certifiable. He thought it would be better for the judicial authority to see a patient, in preference to telling a patient he could see the judicial authority. He did not see any special advantage in having two medical certificates. In reply to Lord Russell, who asked whether care was take to let the patient know that it was when the judicial authority was present that the opportunity for an appeal against incarceration occurred, he said the point was that the judicial authority must satisfy himself that the patient must be detained.

Mr. Snell asked whether the desire of the medical proprietor to cure his patients quickly was due to his wish to have a good statistical record. The witness replied that there was no financial reason against it, as there were always plenty of new patients. When a man was approaching the stage of convalescence, his attention was drawn to the fact by the medical proprietor.

Answering Mrs. Mathers, the witness said that difficulty was sometimes experienced in getting relatives to undertake to look after patients on their discharge from the institution.

Sir Humphry Rolleston, dealing with the protection to medical men certifying which the witness wished to have increased by law, asked whether Sir James Barr had any suggestions to offer.

In reply, the witness said he had no specific recommendations, but at present medical men felt so strongly on the matter that unless a man or woman were palpably and dangerously insane they could not be got to certify. They felt they might be liable at any time to have to withstand an action at law. He added that he would prefer the mechanism for dealing with incipient cases to be attached to the mental hospital, in preference to a general hospital, such as the Liverpool Royal Infirmary; it would be more specialised, and the surroundings and atmosphere would be quieter and more congenial.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the health statistics for three counties and three boroughs for 1923:—

Name of county or borough.	Estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Kent	1,075,408	18·3	10·6	0·95	1·4	1·4	25	48	3·2
Essex	930,360	18·6	9·8	0·83	1·3	1·5	25	46	3·2
Cheshire ..	636,300	17·3	11·1	0·77	1·2	2·2	31	65	4·5
Ealing	68,120	15·6	10·6	1·03	1·7	1·8	—	58	3·8
Wimbledon ..	58,000	14·9	9·4	0·64	1·2	1·6	25	44	1·1
Dover	40,740	21·5	10·4	0·81	1·6	1·6	21	50	3·4

Kent.

Dr. Alfred Greenwood draws attention to the effect of the housing shortage on the birth-rate. Many young people are prevented from getting married and those who do marry have often to live in rooms where children are not wanted. The highest infant mortality-rates among the urban districts in the county were 72 in Penge and 64 in Chislehurst, while Lydd and Sandgate had 44 and 43 births respectively and no infant deaths. The lowest rates after Lydd and Sandgate were Sandwich 15, Herne Bay 19, Tenterden 21, and Ashford 24. Among the rural districts the lowest rates were 13 in Blean, 25 in Maidstone, 26 in Thanet, and 28 in Tonbridge, while the highest were 77 in Tenterden, 69 in Bridge, 68 in Faversham, and 65 in Cranbrook. For the whole county the infant mortality-rate was the lowest on record.

The notifications of enteric fever totalled 115 as compared with 87 in the previous year. In Rochester city three schoolboys were thought to have contracted the disease from eating monkey-nuts spilt into the mud of the river near the sewer outfall during the unloading of a cargo. The endeavour to form "care" and "after-care" committees throughout the county for tuberculous patients is only meeting with partial success. In many districts the attitude adopted towards the movement is that this is the business of the State, that it is difficult to raise the necessary funds, and that such committees cannot find employment. The county tuberculosis scheme does not include the home nursing of tuberculous patients. Dental treatment, ancillary nourishment, and surgical appliances are provided in cases where the financial circumstances of the patient are insufficient. There are 87 open-air shelters in use and these are much appreciated. They were used last year by 129 patients, and particular care is paid to the suitability of the site chosen for the shelter. Thirty-one cases from Kent were admitted to various vocational training colonies during the year; and 29 patients were discharged, of whom only 11 completed their course of training. The opinions of the tuberculosis officers in the county vary considerably as to the benefits of sanatorium treatment as at present carried out. Dr. F. J. Pierce, medical officer of Lenham Sanatorium, speaks of the useful work done by the training section at Lenham. Two trades are taught—namely, furniture repairing and upholstery, and general house repairs. Of the 49 men discharged from Lenham during the year 30 completed the 12 months' course of training and were found to be adapted to the new trade and in several instances exceptionally capable workmen were turned out. The training section have effected a valuable improvement by the completion of a verandah for the west wing of the sanatorium. Commenting on the high death-rate from cancer, Dr. Greenwood says this disease may be now said to have usurped the title formerly bestowed on tuberculosis—"the white man's scourge." A study of the table for the six districts confirms this dictum. Details are given of the efforts made to coördinate cancer research by the institution of the British Empire Cancer Campaign in the early part of the year.

Dr. W. L. Cassells, the whole-time V.D. medical officer, gives a hopeful report on the work. He thinks the work of the clinics is largely responsible for the decrease in the number of new cases. A considerable number of congenital cases have been sent to the clinics as the result of lectures given during the summer to the nurses, midwives, and health visitors, on the signs and symptoms of venereal disease. The attendances at the clinics show an increase largely owing to the better facilities for the intermediate treatment of gonorrhœa. The list of general practitioners approved for "arsenobenzol" treatment now contains 86 names. The work of the county pathological laboratory increases steadily, and an experimental branch was established during the year at Sheerness. The laboratory has been approved for official examinations of Grade A and certified milks. A large variety of work is carried out, including the examination of tissue sections and blood-sugar tests.

Essex.

Dr. W. A. Bullough refers to the bad reputation which Essex "seems to possess" with regard to tetanus. "A London coroner, in August, stated that about a dozen deaths from lockjaw, which had been brought to his notice within the last two years, had all come from Essex." The heavily manured market-garden land round about Barking, Romford, &c., seems to be indicated by rumour. Dr. Bullough has been investigating. He finds that the deaths from tetanus in Essex during the four years 1918–21 number 3·7 per cent. of the total tetanus deaths in England and Wales, whereas the population of Essex is 2·4 per cent. of the population of England and Wales. He thinks the result cannot be regarded as a justification for the bad tetanus reputation of the county. A prophylactic serum is supplied to any medical practitioner by the public health department and during 1923 three doctors were so supplied. A small outbreak of typhoid fever at Saffron Walden was thought to be associated with an insanitary encampment of van-dwellers. A number of the local children attended their entertainments and purchased sweetmeats from these people. In the case of another small outbreak at Tendring, the first case was thought so have contracted the infection by bathing in the Stour at a place where the water is unsafe to drink. The boy infected had been submerged and had swallowed a considerable quantity of water.

The public health department during 1923 undertook some research work into the possibility of a relationship between the amount of silica present in water and the incidence of cancer. The conclusions reached did not indicate any such relationship. Owing to the experience that female patients infected with venereal disease are very reluctant to attend clinics, the experiment has been tried of treating infected mothers and children at their own homes. The report as to the alleged disease has been received from midwives and others and the treatment has been successfully carried out by two women medical officers on the county staff. It is hoped to extend this method of treatment.

Cheshire.

Dr. Meredith Young says that for the first time it is possible to give the cost of the various public health services of the county per head of the population. They are as follows :—

	Pence.
Maternity and child welfare	2·427
Venereal diseases	0·218
Tuberculosis	4·783
General public health	0·711
Mental deficiency	0·844
Medical inspection of school-children ..	2·623
Total	11·076

There are only nine other counties in England and Wales, he says, where the total cost of these public medical services is lower than in Cheshire. The county has at present six county midwives who receive a grant of £60 per annum and keep their own fees. The grant is given to enable a midwife to settle in an area where there is no trained midwife practising and is withdrawn when she has a practice sufficient to support herself. Of the 250 practising midwives 181 are trained and 69 are untrained. Twenty-six of them cannot take the temperature or pulse of their patients. The number of cases of ophthalmia has steadily lessened since each midwife was provided with collosol argentum in a drop-bottle. Of the 56 cases of ophthalmia, four severe cases were treated in hospital and a nurse was engaged to attend four other cases at home. All the cases are said to have recovered without any scar or injury to sight. Building activity has been moderately well maintained, and there is a tendency to urbanisation in many parts of the Wirral rural district.

Very few local authorities have put into operation the full powers conferred by the Milk and Dairies (Amendment) Act. Most of the farm buildings inspected by Dr. Young leave a great deal to be desired in the matter of cubic space ventilation and cleanliness. Very few local authorities have initiated any system for the detection of tuberculosis in cattle. Dr. Young points out that the medical officer of a large town, in the case of a milk-borne outbreak, is put in a difficult position by the fact that the milk may be a mixture of milks from a score or more of farms. In the case of a recent outbreak in a metropolitan borough the suspected milk came from 100 different farms. Dr. Young thinks it would be an immense help to such a medical officer if he were able to rule out the carefully managed farms and concentrate on the undesirable ones. Unfortunately for Dr. Young's theory, milk-borne epidemics in the past have frequently been associated with unrecognised cases of disease and have been known to occur in connexion with farms of good repute.

Ealing.

Dr. Thomas Orr mentions that the maternity and child welfare centre and the school clinic are located in the same centrally situated building, and that by this arrangement the work of these two branches of health activity is facilitated and coördination promoted. During the year ten applications for registration as purveyors of milk were received. Of these, two were refused on account of unsuitable premises; one application from a person retailing milk in Ealing, whose premises were in an adjoining district, was granted after the receipt of a satisfactory report from the medical officer of health of this adjoining district. The housing difficulties still remain the same, says Dr. Orr, and little progress can be made until the Government evolve a large and practicable scheme of house building on a good basis. The school report shows a great improvement in the teeth of the children. Thus the percentage of entrants with sound teeth has gone up from 23 in 1915 to 55·2 in 1923, the percentage of the "intermediates" from 26·2 to 52·5, and the percentage of "leavers" from 35·7 to 80·5. As regards the improvement in the infants, Dr. Orr can only attribute it to the steady educational work done by the health visitors and school nurses. The parents are beginning to appreciate that sound teeth are of prime importance to health, and that the best way to secure sound teeth is by proper mastication, the selection of a suitable diet, and the avoidance of sweetmeats between meals.

Wimbledon.

Wimbledon, says Dr. A. Gilmour, has always been regarded as one of London's most desirable dormitories. Many persons are desirous of residing in this district, but to build houses which would only be attractive to those at present residing outside the district would do nothing to relieve the overcrowding that exists. Besides, the Wimbledon area is practically built up with the exception of a few isolated sites to which restrictive regulations apply, or which are not on lines of transport. The congestion in Wimbledon can, therefore, only be relieved by building in other districts. Owing to the need for internal structural repairs, the accommodation of the South Wimbledon day nursery was cut down towards the end of the year from something over 40 to 30. It is surprising to learn that a day nursery is needed at Wimbledon. One reason is the number of laundries in Wimbledon which attract the working mothers. Another reason is the dearth of domestic servants. The occupations of the mothers for 1923 were, principally, laundresses 22, domestic servants 6, and charwomen 9. The proportion of widows is not stated. Economically the proposition appears to be this. A staff of eight, consisting of a matron, a nurse, a cook, and five maids, look after the children of about 40 women, in order that these latter may go out to work elsewhere as laundresses and domestic servants. The payments made by the mothers are 6*d.* for one child, 10*d.* for two, and 1*s.* 2*d.* for three per day. The whole scheme is only rendered possible if subscriptions or State and rate subsidies are forthcoming.

Dover.

Dr. A. B. McMaster thinks that the provision of an open-air school will be valuable in the prevention of tuberculosis. The question is at present being considered by the education committee. Owing to the continued housing shortage, a number of large houses have been subdivided into flats and others have been sublet as "houses-let-in-lodgings." Dr. McMaster thinks that private enterprise should be encouraged to build more houses under the £100 grant scheme. The particulars given for the port administration show the need for incessant vigilance to prevent the introduction of infectious diseases. The passengers landed at Dover from the five cross-Channel daily services in 1923 numbered almost half a million, being about 100,000 more than in 1921 and 50,000 more than in 1922. About a quarter of the persons landed were aliens and three-quarters Britons, either returning home or visitors from another part of the Empire. The short voyage does not enable the captain of the vessel to know whether he is carrying persons suffering from an infectious disease. Passengers may also be incubating disease, and this has occurred during the year with regard to small-pox. An examination of the customs, railway, and vessels' staffs showed that most of them were well protected by revaccinations done during the war. Another possible source of infection is the passenger who travels overland from Marseilles. Such persons can only be traced by the help of the customs' officers, given readily to the port medical officer. Only four cases suffering from infectious disease were discovered among the passengers and removed to the isolation hospital. They were cases of diphtheria, scarlet fever, whooping-cough, and chicken-pox respectively.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 13TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 82; scarlet fever, 2026; diphtheria, 1103; enteric fever, 66; pneumonia, 1136; puerperal fever, 37; cerebro-spinal fever, 10; acute poliomyelitis, 15; acute polio-encephalitis, 1; encephalitis lethargica, 41; continued fever, 1; dysentery, 14; ophthalmia neonatorum, 104. There were no cases of cholera, plague, or typhus fever notified during the week. Of the 14 cases of dysentery, two were reported from Macclesfield, 1 from Bristol, 1 from Liverpool, 1 from Clitheroe (R.D.), 2 from Leicester, 4 from Friern Barnet (Msx.), 1 from Woking, 2 from Reigate.

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, none from small-pox, 11 from scarlet fever, 38 from diphtheria, 59 from measles, 86 from influenza. In London itself the deaths from diphtheria numbered 14, and from infantile diarrhœa 7.

Obituary.

HERBERT WILLIAMSON, M.A., M.B., B.CH. CAMB., F.R.C.P. LOND.,

PHYSICIAN ACCOUCHEUR TO ST. BARTHOLOMEW'S HOSPITAL.

IT is with consternation that his contemporaries and many friends have learnt of the unexpected death of Dr. Williamson, at the age of 52. He seemed, least of all men, doomed to die in the plenitude of his powers, and indeed of late years he appeared to those who watched his career to grow in stature both as a physician, a trusted colleague, and a wise and prudent man of affairs.

When Herbert Williamson first came to London and St. Bartholomew's Hospital from Cambridge, in 1894, he very quickly made a mark, and even before he was qualified was recognised by his teachers—and, what is perhaps more significant, by his fellows—as a man of exceptional powers of mind and industry, and still more of exceptional charm. There were few indeed who knew him in those days who did not foresee for him a fortunate and prosperous career; and when after qualification and the holding of the usual house appointments he appeared for a time to hesitate between the claims of surgery and gynæcology, it did not to his contemporaries appear to be a matter of much moment. Whichever career he should choose they felt he must arrive among the first in the profession. Nor were they deceived. From the moment he began to teach it was clear that beyond other men he had the gift of imparting knowledge, and from the moment he entered on private practice it was evident that his care and clinical instinct, backed by his personal charm, were an assurance of success.

He was already in extensive private practice when in 1906 an opportunity arrived for his seniors to recognise his merits by the creation of an additional post in the obstetric and gynæcological departments, and Williamson became a member of the staff of St. Bartholomew's Hospital earlier than any of his contemporaries. Since that date, as his seniority has grown so has his influence in all the councils of his colleagues, and for the last few years none has been in such request for guidance and deliberation in all the manifold difficulties of post-war hospital work. Nor were his merits in this respect unvalued outside his own school, and he undertook much work in various connexions, as an examiner and on committees concerned with the teaching of his subjects. Of his private professional work it need only be said here that he had all and often more than he could possibly manage to do, and that his devotion to his hospital, and no less to his private patients, led, no doubt, to the deterioration in the good health which he had for many years enjoyed. None, however, could have supposed, even in the last few weeks, that his health was seriously undermined, and even his closest friends and the colleagues most intimately associated with him in work did not suspect more than a passing indisposition. He left his home, it is believed, for a walk, hoping to rid himself of the malaise and lassitude induced by a recent attack of influenza and by a consistent habit of overwork, and, we may hope, passed suddenly and painlessly from the world which respected, admired, and loved him.

"Audi alteram partem."

HONEY: ITS VALUE IN HEART FAILURE.

To the Editor of THE LANCET.

SIR,—It has been said that the main rôle of carbohydrate in metabolism is to provide fuel for muscular energy. I desire to call attention to the great value, which I believe it to have, of honey as a restorative in health and sickness.

When muscular energy is required, and particularly after emotional stimulation of the sympathetic nervous system, there is found to be an increase of sugar in the blood. The various sugars found in the body may be classified among the mono- or the poly-saccharides: glycogen belongs to the latter group, and is apparently a storage product in muscles as well as in the liver. The energising effect of sugar on muscular effort has been proved by Schumberg's experiments with the ergograph. Muscle in action, it has been computed, can consume three and a half times as much sugar as muscle at rest. Starling found that the normal heart used up sugar at the rate of about 4 milligrammes per gramme of heart per hour. Nectar, which bees collect from various flowers, contains a special sugar which undergoes some change to honey.

The question is whether honey does not contain some special vitamins, and if boiling destroys certain vitamins, then, presuming honey contains vitamins, there is an advantage in honey over commercial sugar. If sugar, and pre-eminently honey, be the most potent fuel to provide energy for muscle, should we not remember to give it for that all-important and most vital muscle of all—the heart, which gets no complete physical rest: other muscles, yes, but, for the heart, no respite—until "the tale is told."

In severe cases of malnutrition with heart weakness I have found honey to have had a marked effect in reviving the heart's action, and keeping the patient alive, and I had further evidence of this in a recent case of pneumonia. The patient consumed 2 lb. of honey during the illness; there was an early crisis with no subsequent rise of temperature, and an exceptionally good pulse. Instead of depending on milk and beef extracts, as is done in so many cases of fever when the stores of sugar in the body are being rapidly used up, I suggest that honey should be given for general physical repair, and above all, for heart failure, and for reasons similar to those set out above, grapes constitute a valuable adjuvant. Herbivorous animals thrive in clover, no doubt because of the nectar, which is probably vitaminous, in the white and red clover flowers. "My son, eat thou honey, because it is good" (Prov. xxiv. 13).

I am, Sir, yours faithfully,
G. N. W. THOMAS, M.B., Ch.B. Edin.,
Of the Middle Temple and S. Wales Circuit,
Dec. 15th, 1924. Barrister-at-Law.

INTUBATION OF THE COMMON BILE-DUCT FOR STRICTURE.

To the Editor of THE LANCET.

SIR,—The case reported in THE LANCET of Dec. 6th by Mr. Zachary Cope interests me, as I carried out the same treatment in 1917. In my patient, the stricture was high up in the common hepatic duct, and was the result of a bullet wound. The gall-bladder had previously been removed elsewhere. Bile flowed freely from a thoracic sinus, where the bullet had entered; the patient was jaundiced. After some trouble I opened up the stricture, dilated it, and drained the abdominal wound. The immediate result was good, but the stricture soon recurred. I reopened the abdominal wound and dilated the stricture again: a plastic operation was out of the question, so, in desperation, I fixed a piece of No. 10 Jacque's catheter in the duct. The immediate effect was most satisfactory, the thoracic sinus and abdominal wounds healed, and the patient, who had been deeply jaundiced, regained his colour and health. This improvement was, however, only temporary. Twelve months later signs of biliary obstruction recurred, and the patient showed evidence of infection. I reopened the wound and found the bile-duct completely blocked by the tube, which was coated and entirely filled with bile salts and debris; it was removed. The patient died one week later. Extensive suppurative cholangitis was found in the dilated bile-ducts in the liver.

About the same time, curiously enough, a similar case was operated upon at St. George's Hospital by the surgical specialist who had had charge of my patient at the Military Hospital. A woman, aged 36, was admitted, with signs of biliary obstruction and infection. Thirteen years previously she had been operated on by the late Mr. Clinton Dent, who removed a gall-stone, which was impacted in the common bile-duct. Later a stricture of the duct occurred. For the relief of this Mr. Dent implanted a piece of rubber tubing in the duct. The patient was readmitted in 1917 with obstructive jaundice of two months' standing. At the operation the duct was found to be completely obstructed; the rubber tube, which was blocked, was removed, but the patient succumbed a few days later.

It would appear from this experience that intubation of the bile-duct is a risky procedure, but the condition is a desperate one and the risk taken is justified if a plastic operation on the duct is impracticable.

I am, Sir, yours faithfully,
London, Dec. 8th, 1924. HUGH M. RIGBY.

Medical News.

UNIVERSITY OF LONDON.—At recent examinations the following candidates were successful:—

M.D. EXAMINATION.

Branch I., Medicine.—Eric A. Coldrey, St. Bart.'s Hosp.; Calvert M. Gwillim, St. Bart.'s and St. George's Hosps.; Robert Hunt Cooke, St. Bart.'s Hosp.; Charles G. Lewis, University of Birmingham and Univ. Coll. Hosp.; Ivor Lewis and Bruce Maclean, Univ. Coll. Hosp.; Bertram Sydney Nissé (University Medal), London Hosp.; Donald C. Norris, London Hosp. and Université de Paris; Owen W. Roberts, King's Coll. Hosp.; Kathleen A. H. Sykes, London Sch. of Med. for Women and Univ. of Liverpool; and Raghunath Sabaji Tirodkar, Univ. Coll. Hosp. and Grant Medical College.

Branch IV., Midwifery and Diseases of Women.—Bryan L. Jeaffreson, St. Bart.'s Hosp.

Branch VI., Tropical Medicine.—Maurice L. C. Irvine, St. Thomas's Hosp. and London Sch. of Tropical Medicine.

M.S. EXAMINATION.

Branch I., Surgery.—Oscar S. Hillman, Middlesex Hosp.; and David Levi, St. Mary's Hosp.

UNIVERSITY OF CAMBRIDGE.—At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR MEDICAL AND SURGICAL DEGREES.

Part I., Surgery, Midwifery, and Gynæcology.—F. N. Adams, Caius; C. Adamson and N. F. Adeney, John's; G. L. Alexander, Trinity; R. D. Alexander, King's; T. F. Anderson, Trinity House; W. A. Bourne, Christ's; H. F. Brewer and W. Brockbank, Caius; A. D. Briscoe, John's; B. H. Burns, Clare; W. E. Chiesman, Corpus Christi; W. R. F. Collis, Trinity; J. W. E. Cory, Trinity House; J. E. D. Crozier and R. W. Cuningham, Caius; C. H. C. Dalton, King's; G. H. Day, Sidney Sussex; F. M. Deighton, Trinity; M. S. Dewhurst, Emmanuel; R. H. Dyer, Clare; H. W. Eddison, Christ's; J. L. Edwards and J. H. Gaddum, Trinity; N. T. Glynn, Clare; H. G. Goldwater, John's; H. F. Griffiths and K. E. Harris, Caius; J. Holmes, John's; W. Hunt, Christ's; J. J. Keevil and M. C. H. Kingdon, Caius; A. R. Lister, Trinity; D. P. Marks, Corpus Christi; L. P. Marshall, Sidney Sussex; J. G. Milner, Trinity; W. J. Montague, Selwyn; M. F. Nicholls, Clare; L. J. Panting and P. E. Pym, Caius; W. Richards, Emmanuel; D. Riley and J. Russell Smith, Caius; F. R. Sandford, Queen's; A. de M. Severne, Christ's; A. J. Smyth, Emmanuel; E. W. P. Thomas, Clare; E. J. E. Topham, Emmanuel; E. A. Trim, Christ's; J. G. E. Vachell, Jesus; T. E. Walsh, King's; A. G. Walter, Clare; H. A. Ware and J. L. Warner, Caius; and I. M. Harmer, Girton.

Part II., Principles and Practice of Physic, Pathology, and Pharmacology.—P. E. Bardsley, Caius; A. Barker, Christ's; W. S. C. Copeman, R. Cove Smith, and W. I. Daggett, Caius; J. H. Doggart, King's; H. G. English, Clare; M. W. H. Evans, Caius; R. B. Fawkes and J. A. Galletly, Queen's; W. H. Gervis, Caius; T. S. Goodwin, Pembroke; J. Gray, non-collegiate; F. N. Green, Magdalen; H. E. Harris, Christ's; K. E. Harris, Caius; B. D. Hendy, Downing; R. A. Highmoor, Clare; F. D. Howitt, Trinity; P. W. Jamie and A. A. Lees, Emmanuel; W. A. Lister, Trinity; S. M. Milner, King's; E. G. Morris, Clare; A. C. Mowle and H. B. Padwick, Emmanuel; T. M. Preece, John's; R. H. T. Rea, Caius; W. G. Scott Brown, Corpus Christi; F. A. H. Simmonds, Emmanuel; T. H. Sims, Pembroke; J. D. M. Stewart, Caius; G. B. Tait, King's; G. L. Thompson, Trinity; J. H. G. Thompson, Caius; and G. B. W. Walker and H. Yates, King's.

University of Liverpool.—At examinations held recently the following candidates were successful:—

Degree of M.D.

E. N. Chamberlain and A. R. Jones.

Degree of M.Ch. Orth.

E. B. M. Vance.

Final Examination for Degrees of M.B. and Ch.B.

Part III.—B. E. Acland, M. M. F. Arthur, P. D. Barling, T. Bellis, E. C. Benn, T. A. Clarke, H. A. Cole, R. Cotter, W. R. H. Ellis, E. A. R. Evans, C. G. Foxcroft, G. A. Fulton, J. Gaughan, Clara M. V. Gleave, H. Gobie, M. Godwin, W. J. Griffiths, A. D. Harper, L. F. Henry, Bertha H. Irvine, E. W. Johnson, C. P. Jones, G. F. Kinder, B. D. Knoblauch, Sarah Leigh (with distinction in Surgery), A. Oserovitz, R. D. Owens, J. T. C. Roberts, C. Sharp, R. S. Turner, G. R. Wadsworth, and T. W. White.

Part I.—J. L. Clegg, J. C. Edwards, A. B. Follows, J. F. Galloway, Elinor M. Gelling, M. Goldberg, Elizabeth M. Harding, D. G. Henry, B. S. Jarvis, A. N. Jones, J. S. Logan, M. A. Lombard, D. B. Macaulay, G. McLoughlin, R. M. Maher (with distinction), F. Murgatroyd, A. V. Russell, M. R. Sheridan, J. E. Wallace, R. G. Walmsley, Kathleen M. Ward, and Nora M. Wilson.

Part II.—Alice M. Luck, Isabel McKee, D. J. T. Magowan, J. Morrissey, Irene M. Neal, Mary T. Penrice, W. J. Pierce, Thirza Redman, and D. Roberts.

Diploma in Tropical Medicine.

H. S. Bilimoria, B. L. Davis (recommended for the Alan H. Milne Medal), C. B. Jennings, S. W. S. Lee, G. Macdonald, J. M. Mitchell, D. U. Owen, Beryl Palmer-Jones, E. J. Sankeralli, and H. Singh.

University of Sheffield.—In the recent Final Examinations for the degrees of M.B., Ch.B. the following candidates were successful:—

John R. Baker, Michael J. Finkelstone, Alys M. Gregory, Josias W. Jago, Oscar H. Swede, and Margaret Wesley.

University of Edinburgh.—At the graduation ceremonial on Dec. 19th the following degrees were conferred:

Doctor of Medicine.

Frederick C. K. Austin, Leslie C. L. Averill, James Brown (in absentia), *Nicholas S. Craig, †Douglas R. Cramb, *Alexander M. Drennan, Alexander D. Edington (in absentia), †Jessie Eeles, John W. Gray, John S. Harris, Frederick T. Ingram, †John M'Garrity, Douglas S. Robertson, Hilda D. Scott (in absentia), and †Muriel J. Thomson.

* Awarded Gold Medal for Thesis.
† Highly commended for Thesis.

Royal College of Surgeons of Edinburgh.—At a meeting of the College on Dec. 17th the following candidates, having passed the requisite examinations, were admitted Fellows:—

Ramrao N. Ajinkya, Thomas F. Andrew, Prabhat K. Bardhan, Edwin J. Bradley, Robert C. E. Brodie, Cecil J. Cellan-Jones, Joseph R. de Witte Connolly, David Cromie, Charles M. Eynon, Lawrence S. Fallis, Charles K. Fuller, Robert McM. Glynn, William A. Jackman, Arnold Leeming, Alexander P. G. Lorimer, Reginald F. Matters, Denys F. Murphy, Edgar R. Reay, Lambert C. Rogers, Evan K. R. Thomas, Victor H. Wallace, William G. Waugh, Robert T. Wells, and Angus H. Whyte.

London School of Hygiene and Tropical Medicine: *Research Appointments.*—Dr. H. H. Scott, at present assistant director in the Department of Helminthology in the Tropical Division of the School, has been appointed Milner Research Fellow in Comparative Pathology as from Jan. 1st, 1925. This appointment has been rendered possible by the coöperation of the Council of the Zoological Society, on whose premises Dr. Scott will carry out most of his investigations. Dr. Edward Hindle, until recently professor of biology (including parasitology) in the Cairo School of Medicine, has been appointed to undertake research work in spirochætosis.

Tropical Diseases Library.—The third annual report of the librarian has just been issued. On July 31st the library completed its third and last year under the trusteeship of the Seamen's Hospital Society. It passed, on August 1st, under the control of the newly-constituted London School of Hygiene and Tropical Medicine (University of London). The volumes of periodicals belonging to the Tropical Diseases Bureau will remain as before on permanent loan in the library. During the past year the net increase in the library stock was 179 volumes.

Sir William Arbuthnot Lane has undertaken the editorship of *The Practitioner.*

We regret to announce the tragic death, on Dec. 21st, of Dr. C. J. Pentland, as a result of a motor collision outside his house in Gower-street.

The late Dr. J. McGibbon.—John McGibbon, M.B., C.M. Edin., who died suddenly last week at his residence, 83, Durning-road, Liverpool, at the age of 62, will be greatly missed by the Scottish community resident in the city. He had long been a leading figure in all activities linking him with his native land, such as the Burns Club, the annual Caledonian dinner, and the Old Watsonian Society, of which he was treasurer. Dr. McGibbon graduated at Edinburgh University in 1884. He leaves a son, who has been associated for some years with him in practice.

Yorkshire Association of Graduates of the University of Glasgow.—The annual dinner of this association was held in the Great Northern Hotel, Leeds, on Dec. 5th, when there was present a company of 90 members and friends. Dr. G. Hanson (Bradford), the President, was in the chair. The chief guest of the evening was Prof. John Glaister, and Dr. J. B. Baillie, the recently appointed Vice-Chancellor of Leeds University, was also present. The annual report shows that the association is in a flourishing condition, there being now a membership of 126. Membership is open to all Glasgow graduates resident in Yorkshire, and further particulars may be obtained on application to the hon. secretary, Dr. W. MacAdam, Cromer Hall, Leeds.

The late Dr. J. B. Edis.—John Butler Edis, L.R.C.P. Edin., M.R.C.S. Eng., who died recently in Liverpool, was born in 1847, and qualified in medicine in 1871. He was a well-known figure in Liverpool medical circles, and was widely respected for the skill and care he devoted to the poor, who formed a large proportion of his practice. Although at one time senior surgeon to the Liverpool Hospital for Women, Dr. Edis found his main outlet in general practice, where his special knowledge made him much sought after. In his early life he had found great inspiration in the friendship of Dr. Barnardo, and his activities outside his profession were coloured by his influence. He died at the advanced age of 77, having celebrated his professional jubilee three years ago, when he received the congratulations and felicitations of his numerous friends in the Liverpool Medical Institution,

The late Dr. E. B. Roberts.—By the recent death of Edward Blackwell Roberts, after several weeks' illness, at his residence in Hawarden, Chester, at the age of 60, the village of Hawarden, where he had practised for over 30 years, has suffered a great loss. After studying at the University of Edinburgh and its extra-mural school in 1889, he qualified as L.R.C.P. & S. Edin., and L.R.C.P. Glasg. Dr. Roberts was medical officer for the county, the public vaccinator and Government factory inspector, and held besides a number of medical public appointments. He took a keen interest in all the social affairs of Hawarden, and was a prominent figure at any festival or sports meeting in the neighbourhood. In his earlier days he was an enthusiastic cricketer. His professional services were held in high regard by all classes of the community, and he was a generous though unostentatious donor in many cases of need. He is survived by his widow, one son, and three daughters.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Tuesday, Dec. 16th.

Government Housing Policy.

The debate on the Address in reply to the Speech from the Throne was resumed.

Mr. Wheatley (who was Minister of Health in the late Labour Government) moved an amendment regretting that the Government were committed to a policy of leaving the solution of the housing problem mainly to private enterprise and the operation of occupying ownership, thus ignoring the importance of carrying out a long term scheme of building houses at rents within the means of the working classes and failing to take every advantage for increasing employment in the building and auxiliary industries.

Mr. Neville Chamberlain (Minister of Health) replying said that under the 1923 Act the number of houses approved up to date in the case of local authorities was 53,535, and in the case of private enterprise 116,858. For the 12 months ended Sept. 30th last there were built 110,000 houses. Of these, 14,500 odd were built by local authorities and 95,362 r 86 per cent., by private enterprise. The maximum number f houses ever built in the country in one year was 129,000. o-day in spite of the extraordinary limitations of labour nd material they had got within 19,000 of that figure. f the 110,000 houses he had mentioned, 90,000 were of a ateable value of under £26 a year. On Oct. 1st there were nder construction another 92,000 houses, of which 71,000 vere built by private enterprise. The scheme organised by Ir. Wheatley for the augmentation and better distribution f labour and materials was in his (Mr. Chamberlain's) view statesmanlike piece of work, and work in the right direction vhich he would support by every means in his power. he Government did not intend to proceed with the Bill ntroduced by Mr. Wheatley to deal with the cost of materials. he Government would, however, keep a watchful eye on uilding costs, and if they found that there was any reason o believe that the public were being exploited by anybody hey would take their own measures to stop the exploitation. peaking of Lord Weir's new method of house construction, Ir. Chamberlain said that recently he paid a special visit o Glasgow to see what was being done by Lord Weir and e came back very hopeful. He had made an arrangement hereby Lord Weir had undertaken to set apart a part of is factory for the production of a certain number of emonstrations of experimental houses to be supplied by cal authorities. With the concurrence of the Chancellor f the Exchequer he had set aside a sum of money in order give a grant to any local authority taking these xperimental houses. Lord Weir had authorised him to say hat the cost would be lower than that of a brick house. Ir. Chamberlain stated that he would give Mr. Wheatley's ousing Act a fair trial and it was not his intention to iscourage local authorities or throw any difficulties in their ay. The Act should stand or fall on its own performance ; ut he could not promise that if it failed it would emain in its present condition.

In the course of the subsequent debate,

Dr. **SHIELS** said that Scotland suffered very much more om bad housing than England ; 49 per cent. of the opulation of Scotland lived in one- or two-roomed houses. uberculosis figures varied exactly according to the density the population, and the situation in Scotland required ecial treatment because of that fact. Slum property had ot been seriously tackled in the great cities of Scotland. both Edinburgh and Glasgow whole streets had been ndemned by the medical officers of health and yet people ent on living in them. While the problem was a difficult ie it was not, he thought, incapable of solution. He would ke to see a town-planning scheme for every area. The uestions of heating and ventilation required more expert tention than they had hitherto received. The smoke oblem also required to be dealt with. He was glad to see at local authorities were now paying attention to the uestion of providing a hollow space in the outer walls of uses. In the medical press lately there had been a scussion about the prevalence of tuberculosis in districts hich were exposed to the prevalent rain-bearing winds. seemed a rather far-fetched idea, but houses were exposed a great deal of rain, especially when there was a strong ind and they were apt to become very damp and remain so r days at a time. There might be a connexion between is dampness and the absence of a hollow space in the iter walls. We were still going on in the same old iscientific and haphazard way of house-building. Until iblic authorities from Parliament downwards took a deeper terest in these questions there would never be a satis-ctory solution of the housing problem, which was responsible ery year for many deaths both of children and adults.

On a division the amendment was defeated by 356 votes 136—Government majority, 220.

WEDNESDAY, DEC. 17TH.

Government and Condemned Houses.

Mr. **STEPHEN** asked the Minister of Health if he proposed introduce legislation for the reduction of rents of pre-war uses and to prevent property owners obtaining rent for uses which had been condemned by the sanitary thorities as unfit for human habitation.—Sir **KINGSLEY OOD** (Parliamentary Secretary to the Ministry of Health) plied : My right hon. friend does not propose to introduce sh legislation for the purposes mentioned by the hon. ember. The efforts of the Government will be directed wards reconditioning repairable houses and expediting e erection of new houses to take the place of those that are yond repair.

Smoke Abatement Legislation.

Sir **HARRY BRITTAIN** asked the Minister of Health whether could hold out any hope for the introduction during the xt session of the Smoke Abatement Bill.—Sir **KINGSLEY OOD** replied : The Government contemplate the intro-ction of a Smoke Abatement Bill as soon as a convenient portunity arises, but I cannot promise that the Bill will introduced before 1926.

Supervision of Maternity Homes.

Mr. **BARNES** asked the Minister of Health whether he had received requests from local authorities asking for powers of supervision over all maternity homes within their area ; and if he would state his intentions in the matter.

Mr. **CECIL WILSON** asked the Minister of Health the number of local authorities to whom powers had been given enabling them to supervise all maternity homes within their area ; and whether such powers would now be extended to all local authorities.—Sir **KINGSLEY WOOD** replied : The answer to the first part of the question is in the affirmative. These powers have been given to eight local authorities. As regards the second part of the question, my right hon. friend hopes to introduce legislation on this subject as soon as other claims render it possible to do so.

Geneva Proposals on the Opium Problem.

Mr. **TREVELYAN THOMSON** asked the Secretary of State for Foreign Affairs whether the Government was prepared to support the proposal in favour of the second conference at Geneva dealing with the opium problem ; and, if so, would he use all his influence to this end in order that a definite step forward might be taken towards the suppression of the opium traffic.—Mr. A. **CHAMBERLAIN** replied : His Majesty's Government are anxious to do everything in their power to suppress the opium traffic, but there are serious practical difficulties of which account has to be taken. The situation created by certain proposals put forward at the Geneva conference is now under consideration.

On Friday, Dec. 19th, Parliament was adjourned until Feb. 10th.

Appointments.

MACCALLAN, A. F., M.D., F.R.C.S., has been appointed Assistant Ophthalmic Surgeon to the Westminster Hospital and Assistant Surgeon to the Royal Eye Hospital.

Surgeons under the Factory and Workshop Acts : **BELL, H. C.**, L.R.C.P. & S. Irel. (Shardlow) ; **GIBSON, J. A.**, M.D., C.M. Edin. (Lancaster).

Vacancies.

For further information refer to the advertisement columns.

Adelaide University.—Marks Lectureship in Applied Physiology and Sheridan Fellowship. £750.

Birkenhead Borough Hospital.—Third H.S. £100.

Birmingham and Midland Eye Hospital.—Res. Surg. O. £150.

Bristol Mental Hospital.—Second Med. Asst. £400.

Cape Town University.—Asst. to Prof. of Bacteriology. £500.

Chelsea Hospital for Women, Arthur-street, Chelsea, S.W.—Pathologist (gynæcological). £40.

City of London Mental Hospital, near Dartford, Kent.—Second Asst. M.O. £350.

Eastbourne, Princess Alice Hospital.—Res. H.S. at rate of £175.

Leeds University.—Demonstrator in Dept. of Pathology and Bacteriology. £300.

L.C.C. Mental Hospitals Service.—Junior Asst. M.O. £432.

Liverpool Port Sanitary Authority.—Asst. Port M.O. £700.

London School of Hygiene and Tropical Medicine.—Asst. in Helminthology. £500.

Mount Vernon Hospital for Tuberculosis, &c., Northwood, Middlesex.—Asst. Res. M.O. £200.

North Middlesex Hospital, Edmonton, N.—Res. M.O. £200.

Northumberland, Ashington Hospital.—H.S.

Queen Mary's Hospital for the East End, Stratford, E.—Hon. Dental S.

Royal Army Medical Corps.—Commissions.

St. Mary's Hospital, W.—Med. Supt. £400.

Swansea County Borough.—Asst. M.O. £600.

Swindon Borough Education Com.—Oculist. 2½ guineas per session.

Sydney University, New South Wales.—Professorship of Obstetrics £1100.

Winchester, Royal Hampshire County Hospital.—Hon. Asst. S.

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for Greenock District. Applications should reach the Private Secretary, Scottish Office, not later than Jan. 10th, 1925.

Births, Marriages, and Deaths.

BIRTHS.

LIGHTWOOD.—On Dec. 14th, at Cadwgan, Old Colwyn, N.W., the wife of E. Eric Lightwood, M.D.—a daughter.

DEATHS.

COOPER.—On Dec. 18th, at Warminster-road, S. Norwood Park, S.E., Deputy Surgeon-General Clarence Cooper, F.R.C.S., aged 94.

WILLIAMSON.—On Dec. 16th, Herbert Williamson, M.B., B.Ch. Camb., F.R.C.P.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

ALASTRIM AND VARIOLA.*

Note Presented to the Committee of the Office Internationa d'Hygiène Publique in its Session of October, 1924,

BY PROF. RICARDO JORGE (LISBON),
DELEGATE FOR PORTUGAL.

THE RASH.—(*Continued from p. 1321*).

Carini strikes a different and somewhat pessimistic note. This San Paulo doctor, who, by the way, is a convinced unicist, states that he has observed intensifications of alastrim; in the village of Rio Claro the case-mortality reached 8 per cent., and in San Paulo it was as high as 14·5 per cent., figures not unlike that of small-pox. This happened in 1912, and so far as I have observed up to the present there has been no repetition of the experience. Mitchell alone contends that alastrim may attain an epidemic intensity ranking with small-pox, but he adduces no observations in support of his statement. One may admit the possibility—and perhaps this is the explanation of the occurrences at San Paulo and elsewhere—of the confusion of cases of true small-pox with those of alastrim. Carini anticipates this objection, but does not succeed in rebutting it. I ought to add that at Haiti in 1920 Brown observed an epidemic in which the infection was imported from Jamaica where alastrim was prevalent at the time; the cases were at first mild, but gradually a severe type developed. Apparently similar observations have been made in the United States. It is, of course, intelligible that small-pox may occur coincidently with alastrim, in which case it would be impossible to be sure which variety of infection one is dealing with in considering the outbreak. Similarly cases of varicella also occur fairly frequently at the same time as alastrim, as has been the case with varicella and small-pox.

The outbreaks of alastrim, however, have in their totality been so numerous that one can assert as their characteristic that, however extensive or prolonged they may be, the infection remains almost constantly mild; notwithstanding continual transmission from person to person during several years no intensification of the virus takes place. Observers are practically unanimous in acknowledging the benignity of the disease in contrast with the malignancy of small-pox.

Differences in Severity, according to Type of Rash.

It was not out of mere anxiety for descriptive detail that the classical writers devoted their attention to the abundance and the conjunction of the cutaneous eruption, distinguishing the discrete, the coherent, and the confluent varieties of small-pox: it was because therein lay the possibility of fortelling the outcome of the attack. For there is in small-pox what does not obtain in other eruptive fevers; the rash is an *index* of the mildness or the malignancy of the case—one may say, in fact, that the prognosis is written on the skin of the patient. Bad is it for him who is covered with vesicles; still more to be pitied is he whose pustules are coherent; death hovers over those whose vesicles become confluent. Those cases only are benign in which the eruption is discrete and sparse, better still those in which the rash aborts before the stage of pustulation, as in varioloid.

Now in alastrim, in which all these peculiarities are also observed, it would be a mistake to rely on these paradigms of prognosis; a profuse suppurating rash is associated with the same mild symptoms as in the case of varioloid. Patients covered with pustules from head to foot show no constitutional disturbance and make an uninterrupted recovery. There may be extensive coalescence of these pustules without affecting the recovery; indeed, true confluence may take place immediately in the vesicular stage. The Paris patient, for example, exhibited confluence of the facial rash. Baujean describes some cases of partial confluence observed recently in Martinique, "the vesicles coalescing to form huge ampoules," he says. Such a picture in ordinary small-pox would signify a most ominous prognosis.

Here, then, is surely a striking contrast between alastrim and small-pox. *The lack of correspondence between the local and the general condition of the patient, the absence of correlation between the outward signs of severity and the uniformly favourable termination of the disease.* On this, certainly the most remarkable feature of alastrim, dispute is no longer possible.

Differences in Severity according to Age, Race, and other Circumstances.

Small-pox, like alastrim, attacks all ages, but whilst the former has a preference for children, the latter is more liable to affect adults; the previous vaccinal condition naturally influences the age distribution of those attacked. In childhood not only is the susceptibility to small-pox greater, but the disease is more virulent. In unvaccinated children the mortality is enormous. A sparsely distributed rash in which the pustules are quite distinct may suffice to cause death, and the younger the child the more likely it is to prove fatal. Now unvaccinated children attacked by alastrim come out of the affair even better than adults. The disease with them takes the abortive form. This aborting of the disease in little children has been emphasised by Ribas. The rash aborts during the stage of vesiculation: he has even seen sucklings fail to get beyond the stage of papules with (at most) a few vesicles.

As with small-pox, no race is immune to alastrim; white and black are alike susceptible. In the Antilles and in Africa the latter are, no doubt, almost the only persons attacked; the infection, however, exhibits approximately the same mild character in the two races. But one is aware of the susceptibility of the African races to small-pox, and its virulence amongst them. This is one more contrast with alastrim. In Martinique in 1888 small-pox had raged with the greatest violence; and those who were present at that catastrophe said, with reference to the recent epidemic "If it is small-pox the blacks will die like flies."

The case to which I have already referred and which was photographed by Ribas, is a living witness of all these points of difference—this coloured woman, 15 days after confinement, completely covered with pustules and suckling her new-born baby, who is also covered with an eruption six days' old. This makes a group which it would have been impossible to pose in front of the camera if the mother and the child had been suffering from small-pox. Their condition would have been one of great danger, and instead of preparing negatives one would have been getting ready their death certificates. The influence of pregnancy was ascertained at Sydney, where of 27 pregnant women who were attacked, six aborted, four were confined prematurely and only one died (Robertson). At Ponta Delgada there were three deaths of pregnant women (report by Jaime Neto). Thus alastrim, like small-pox and so many other infections, affects the development of pregnancy, but as a complication it is much less serious.

To sum up, variola and alastrim resemble one another but they are not identical. Alastrim presents a clinical and epidemiological picture which is differentiated from that of small-pox by its local and general characters and by considerations of ætiology. Its most salient characteristics are the almost invariable recovery of the patient and the lack of correspondence between the severity of the rash and the constitutional disturbance. It has a stamp of its own, a noso-epidemiological type, which everywhere and over many years has been evident to doctors and epidemiologists, and has been realised by a popular intuition which put it in a class apart and gave it a name of its own even before the clinicians knew of it.

IV. IMMUNOLOGICAL AND EXPERIMENTAL CHARACTERISTICS: BIOLOGICAL TESTS.

Biological reactions have been used to establish points of differentiation from, or identification between, alastrim and small-pox.

(*a*) *Vaccination Tests.*

Reciprocal immunity is produced between alastrim and Jennerian vaccine, just as between small-pox and vaccinia although with sensible differences. All the observations made go to show that vaccine protects against para-variola. The individuals attacked are found principally among the non-vaccinated. Thus, at Gloucester 469 out of the 498 cases treated in hospital were not vaccinated. According to a memorandum communicated by Sir George Buchanan the investigations made in England show that, in an outbreak of mild small-pox at Ilkeston, out of 100 vaccinated persons living in the houses affected, 15·5 were attacked, whereas the rate of non-vaccinated persons attacked in the same houses was 44·7 per cent.; at Heanor the same quotients were 7·1 and 28·8.

Mr. Carrière has told us that in the Swiss epidemic there were 3372 non-vaccinated persons out of 3479, or 90 per cent. of the total. He attributes the immunity of the cantons which escaped the recent epidemic to the protection afforded by vaccination; these cantons are precisely the ones in which obligatory vaccination† is strictly practised; the disease was arrested at their frontiers as if confronted with an impassable barrier.

The doctors at San Miguel are convinced that the vaccinated and revaccinated escape alastrim, or, that if they are ttacked, the cases abort; the recently vaccinated or vaccinated usually enjoy complete immunity. In districts here vaccination was more thoroughly practised fewer iccumbed. At Terceira intensive vaccination also served protect a large part of the population. Needless to say iat in the Africo-American epidemics the majority of those ho suffered from alastrim was made up of people who had ever been vaccinated, or whose vaccination dated back iany years or even to infancy; this is the reason of the pparent preference of the disease for natives. At Martinique me very striking examples of this preventive power ere collected. Thus, when some members of a family ere vaccinated and others not, the infection respected the rst and attacked the second. In a ward of a hospital irough which an alastrim patient had passed all the atients, to the number of about 30, had been vaccinated xcept one, and he was the only one to contract the infection. ll observers agree that Jennerian vaccination constitutes n efficacious method of preventing the spread of alastrim.

---

* Translated (with slight abridgment and insertion of cross-headings) from the Bulletin of the Office International d'Hygiène Publique, Paris, October, 1924, tome xvi., No. 10.

† In Switzerland this includes obligatory revaccination.—ED. L.

Everything here agrees with the known rules of vaccinal nmunity against small-pox; it should, however, be noted iat persons successfully and recently vaccinated have ntracted alastrim in spite of the fact that the period ad expired which is necessary to establish a condition immunity. Now when small-pox attacks a vaccinated erson, one of the great advantages of vaccination is that ie infection is much slighter, and the eruption may abort often as not. With alastrim, however, it happens com- aratively often that one sees patients with magnificent accinal scars on their arms, but with a profuse rash; l observers have noticed this. Mr. Gouzien has informed that in Martinique five children in one family were tacked by alastrim; three had been vaccinated several ionths earlier; two had not been vaccinated at all, owing their youth, but all were attacked alike; one of the accinated children even had a far heavier rash than his rothers. The Paris patient mentioned had been vaccinated her childhood, and had undergone several revaccinations ith no result before the voyage or while travelling ambassèdès).

Does alastrim reciprocally confer immunity against ow-pox? To a less extent, it would seem, than small-pox, hich itself is a stronger protection against vaccinia than accinia is against small-pox. At Martinique, Baujean oculated with cow-pox 72 convalescents who had never een vaccinated or not vaccinated for many years; the oculation was successful in four cases only, and then not mpletely successsful; it should be remarked that in three these cases the rash had not quite disappeared at the time inoculation. Experiments made by Ribas also helped prove that the immunity produced against vaccinia is either intense nor lasting, for he obtained a positive oculation in the case of a patient who had been con- alescent for 36 days, and seven inoculations were successful the case of a group of 15 individuals who had had astrim six months previously—a percentage of 46. From ght to ten months after the attack of alastrim, Max udolph obtained 27 per cent. positive results of vaccina- on, and Beaurepaire-Aragao obtained vaccinal pustules 11 cases out of 19 who had had the disease less than a ear previously (58 per cent. positive results).

At San Miguel the vaccination of alastrim patients as always negative when performed from one to three onths after the illness. Out of a series of 50, Jaime Neto ad no positive result; a second doctor performed 200 oculations, also with a negative result; others had the me experience. McAllen and Moody conclude that the mild small-pox" immunises, although not very strongly, gainst cow-pox, but that Jennerian vaccination affords great protection against alastrim. Goldsmith and Loughnan not rate this protective power so highly, in view of three ses brought to hospital in Jamaica in 1920, all of them ving been vaccinated, one three years previously, the cond 18 months and the last six months, the former present- g confluence in the gluteal region. The case reported by r. Gouzien would seem to support the same view.

Save for the differences just mentioned, small-pox and astrim may be said to act in a similar way with regard to ie Jennerian reaction. Two things being equal to a third ing are equal to one another, and thus if both diseases t in the same way as regards vaccinia, they must be one id the same infection—this is the argument which the icists deem unanswerable. Now there is nothing to object in the suggestion that the fact of reciprocal immunity irries weight in proving the intimate relationship of the o species, or in using it as evidence of their identity. ut it is most certainly not an incontrovertibly demonstra- ve proof. Vaccinia cannot serve as the crucial test of entification. It is distinct from small-pox, and cannot mistaken for it. The question is one of heterologous imunity. The dispute as to the "unity" or "duality" vaccinia and variola lasted for many years, and within y memory was a burning one. There are still supporters on either side, but just now they appear to be quiescent in their respective strongholds; perhaps alastrim will re-awaken them. If, as so many specialists have affirmed, it is easy to convert the variola virus by passing it through the calf into the condition of "variolo-vaccine," why should not a similar transformation be attempted with alastrim? Beaurepaire-Aragao already had this idea in 1911, and tried to realise it at the Oswaldo Cruz Institute, but the calf inoculation failed. Van Hoof raised the idea afresh last year. These cross-confrontations of alastrim, variola, and vaccinia call for a series of systematic experiments, beginning with the bovine and ascending to the human. Whatever they may show, and even if it is successfully proved that vaccinia and variola are one and the same, they must still remain different from the point of view of their manifestations. So, too, if it is admitted as proved that alastrim and variola are identical as regards their relation to vaccine, their epidemiological differences are not destroyed.

(b) *Paul's Test.*

Experimental Inoculations.—Formerly the routine laboratory test in the case of exanthematic vesicles and pustules was to inoculate their contents into the cornea of the rabbit and examine for the Guarnieri bodies produced there by the small-pox virus; in the case of alastrim the presence or absence of these bodies has been a matter of dispute (Rudolph, Aragao, Carini, &c.). The regulation test at the present day is Paul's reaction; to obtain it the suspected variolous material is inoculated on the scarified cornea of the rabbit; after 48 hours the positive reaction appears in the form of more or less numerous tiny swellings with a punctate depression in their centre which can be made more visible by immersing the excised cornea in corrosive sublimate solution. This reaction is supposed to be pathognomonic of small-pox, being completely absent when the inoculation is made with material from chicken-pox, the various forms of herpes, pemphigus, and purulent dermatitis; in these diseases the only result of the inoculation is a diffuse keratitis.

My assistant, Firmino Pantana, and I have tried Paul's test which has so great a reputation in Germany and Austria in the diagnosis of small-pox; for this purpose we recently obtained from San Miguel (St. Michael in the Azores) a few tubes of alastrim lymph collected from a patient with the greatest care by the sanitary officer, Jaime Neto. The lymph was turbid and yellow with some blood-staining and contained, microscopically, numerous red cells in the case of some of the tubes; in others there was very little blood. The white cells consisted chiefly of lymphocytes, some of them in perfect preservation; the polymorphs were less numerous and were rarely normal in appearance; there were also a few epidermal cells. Direct examination revealed scanty bacteria and culture yielded practically staphylococci alone. Only one of the rabbits employed for the test showed three or four tiny pearls at the end of 48 hours on the scarified cornea; the reaction was thus weak and inconstant.

In Martinique there has been still less success with the test; Baujean got only negative results with 15 different cases. Similarly, at Leopoldville, Van Hoof got only one positive result among numerous corneal inoculations. On the other hand, Read, in San Domingo, obtained positive results, as did Hoffman, who reports 90 to 95 per cent. of successes. In Switzerland Paul's test has been positive in many cases (Carrière). The proof, however, is not conclusive, for, as Baujean has pointed out, a positive Paul's test coincides with a clinical diagnosis of small-pox in only 77 per cent. of the cases according to the German statistics.

Animal Inoculations.

Animal inoculations have been equally unsatisfactory. We tried applying alastrim virus to the shaved and scarified skin of rabbits, but got absolutely no results. Moody and Baujean report the same. Leake and Force, though they got no skin reaction in two rabbits inoculated with the virus of alastrim, found that both the animals were later insusceptible to vaccination. I have already mentioned that Aragao failed to inoculate calves; Moody and Baujean report similar failure. Leake and Force in Jamaica obtained in two monkeys (*Macacus rhesus*) an eruption of papules and vesicles similar to that obtained with small-pox virus in three other monkeys. Baujean got no positive reaction with a monkey of the species called in Brazil *Coaita*. Van Hoof inoculated a monkey (*Cercopithecus*) by scarification with alastrim virus on the thinner skin of the body, the lips, eyelids, the folds of the axilla, and perineum. After the scarifications had healed he injected intravenously 1 c.cm. of the contents of pustules diluted with saline solution; a week later there appeared in the scarified parts a free eruption of typical pustules; in two control animals which received only the intravenous injection this eruption failed to appear. This experiment has some importance. To sum up, animal experiments have produced nothing definite hitherto; the results are confused and contradictory.

(c) *Examination of the Blood Cells.*

It was once hoped that hæmatology would settle the difficulties in the clinical diagnosis of infectious diseases, but experience has shown that this was too optimistic. In small-pox blood examination shows a marked leucocytosis with great increase in the mononuclears and the appearance of myelocytes and nucleated red cells. Sabrazès and Massias have made a complete collection of the reports on the cytology. Baujean (1923), who has done blood counts on several cases of alastrim, has obtained varying results; he has never found nucleated red cells nor myelocytes and, among his 38 cases, he found 14 with a greater or less increase in the mononuclears, while 28 showed no change in the mononuclear count. No definite conclusion can be drawn from these observations.

Hoffman (1923) has put together 300 observations obtained at Havana during an epidemic diagnosed officially as true small-pox, but considered by some to have been the Caribbean alastrim. His conclusion is that in the blood of small-pox patients there is always to be found a very large leucocytosis with very marked excess of lymphocytes and the presence of myelocytes which are invariably absent from normal blood. In chicken-pox the changes in the blood picture are similar, except for the numerical increase in the leucocytes. Hoffman thinks that these investigations, if continued, may solve the question of the identity of alastrim, especially if comparable blood examinations are made in the countries where pure alastrim prevails, and those, such as China and India, where the severest forms of small-pox occur. The complement-fixation test has also failed to give definite results.

(d) *The Allergic Test of Tieche.*

This is the latest application of biological methods. The examination of the allergic reaction of the skin was conceived by Tieche, of Zurich, who took advantage of the Swiss epidemic of 1921–23 to bring it to precision as a means of experimental diagnosis for small-pox.

Skin reactions had already been tried in America; in Leake and Force's conclusions we find, in fact, that rabbits previously inoculated with cow-pox gave positive skin reactions when inoculated by scarification with virulent material from small-pox, alastrim, or vaccinia. Defries and Hanna have also obtained positive reactions with similar sorts of virus by scarifying the abdominal skin of previously vaccinated rabbits.

Tieche's method is quite different; he does not employ laboratory animals for the detection of allergic reaction, but prefers the human subject, in fact, his own body. He had long been making experiments on the von Pirquet reaction. Now it is well known that in small-pox sufferers the allergic reaction produced by the inoculation of their own exudate is weak at the beginning and becomes negative during the period of suppuration. That is to say, the allergic condition is replaced by an anergic state of the skin. Ever since 1907 he had been trying on himself successive inoculations of material from vaccinia and variola the number of these auto-inoculations reaching 3000. The result has been that he has acquired an efficient supersensitiveness of his skin which has finally attained a high degree. The reaction which formerly took 10 to 12 hours to appear now becomes visible in 4 to 5 hours. This incubation period has become a fixed minimum. On the other hand, the intensity of the reaction has diminished. All parts of the skin are equally sensitive for the test, but Tieche prefers as the most convenient the front of the arm. He makes three parallel scratches at a distance of half a centimetre from each other, and notes the time taken for the erythema to become definitely confluent. By means of this procedure he has been able to settle the diagnosis of doubtful cases during an epidemic when atypical forms were abundant, and has been able to distinguish between chicken-pox and pseudo-variola, bullous dermatitis, &c. Out of 515 cases tested he excluded 78 of chicken-pox and 16 of false small-pox. He believes his procedure will give safe results in 98·5 per cent. of cases.

Are we to suppose that this sensitiveness to the variola virus is a property confined to the skin of Mr. Tieche? It appears not, for he has obtained similar results on obliging friends, except that the reactions were less rapid; one person he found to be anergic—his wife.

Mr. Netter, to whom I owe my acquaintance with Tieche's work, suggested to me that I should get him to try the alastrim virus from Ponta Delgada. I have got from Mr. Tieche the results of his test. He has done six experiments on himself, four of which were doubtful, one weakly positive, and one quite typical. On another subject, a young lady of his acquaintance inoculated at the same time as himself, the results were much the same, "but never absolutely typical." On his assistant the reaction was delayed, not appearing till after 19 hours.

V. GENERAL CONSIDERATIONS.

The Characteristics of Alastrim.

From what has been stated above, one is, I think, entitled to infer that alastrim exhibits a "something" peculiar to itself, and which characterises it both clinically and epidemiologically. This special physiognomy may be discerned from a consideration of the descriptions given by various observers of epidemics occurring at different times and at different places. These pictures are, so to speak, prints from the same negative or from superimposed negatives. The common characteristic has forced itself on the attention even of those who would prefer to minimise its importance. Scientific analysis has been able only to define its characters; clinical instinct everywhere recognised that one was dealing with a phenomenon sui generis. The intuition of the public, as we have said before, anticipated that of the professional man, just as happened in the case of the old eruptive fevers which form part of the popular nomenclature of disease. Before Corte and Ribas the savages of Cafrerie and the *sertanejos de Bahia* realised clearly that a new and distinct ailment was attacking them, and they christened it in their own language.

It is impossible to deny these peculiar traits of the disease. Some have laid exceptional emphasis on the differential characteristics, others have deprecated these characteristics, but in their efforts to do so, instead of defacing, have made them all the more noticeable. It has been said that the analogies between the two epidemic varieties now under consideration far outweigh the differences which have been reported. But the more data one collects and the more one discusses the matter, the more impressively do two phenomena emerge. First, the enormous disparity revealed between the local and the general conditions between the profuseness and the confluence of the eruption and the severity of the case; it is the mildness of the symptoms under conditions which, if it were small-pox, would be ample indication of malignancy. Secondly, the persistence of the same morbid facies, as if it were stereotyped, without any appreciable change or variation, right through the epidemics, however long they last, wherever they occur, and whatever the incidence may be.

Of greater infective power than the old-time small-pox and more widespread, the new disease is disseminated in the same manner and with the same train of symptoms. The more it spreads, the more it asserts itself and the more it confirms its own nature—the recent invasion of the Azores is a startling demonstration of this. And this is enough, we believe, to warrant a separate compartment for it, at any rate from the epidemiographic point of view.

I do not see any other lesson to learn from the field of observation. To go further would be to depart from the realm of fact, for, from a scientific point of view, we have as yet no means whereby to solve the problem of the nature of alastrim, in which respect each must form a theory in a way that suits him best.

Alastrim and Small-pox as "Entities."

Generally speaking, one may class the theorists of alastrim into *dualists* and *unicists*, but under each heading one must distinguish rather different grades of opinion. Amongst the dualists are not only those who believe that small-pox and alastrim are of an essentially different nature and are two distinct, although closely related, pathological entities, but also those who distinguish them clinically and epidemiologically without dogmatising on the question of classification. These are, so to say, empiricists who limit themselves to consideration of the facts as they arise, and must not be regarded as dogmatic partisans of an extreme duality theory. I myself have a tendency in this direction. I am inclined to think that when a disease appears epidemically, maintaining its fundamental characters and reproducing itself in the same way, it ought to be classed as a separate morbid entity. Or rather, taking advantage of the locution *als ob* or *as if*, somewhat after the manner adopted in scientific explanation (since Haidinger published his philosophic essay), *things happen as if two separate entities were concerned.*

Differences of opinion are found to no less an extent among the *unicists* who, one must admit, form the largest and most prominent group, especially among the English and Anglo-American authors. Some of them are so conservative that they will not hear of the term alastrim nor its synonyms, regarding them as mere verbalism due to inconsistent and fallacious differentiations. Just as in Mussulman's creed there is *no God but God*, so, they say, there is *no small-pox but small-pox.* Alastrim would then be a variety of small-pox just like any other; but if it were like any other, there would be nothing to dispute about. This conservatism is due in great part to the fear of weakening the anti-small-pox campaign, and this is ıy the official and administrative term "small-pox" is persistently maintained and the use of the term alastrim rbidden. But there is no reason why the same preventive easures should not be applied to alastrim as to small-pox. ıis is a point on which everyone will be agreed.‡ Other unicists," "rendering unto Cæsar the things which are esar's," recognise the epidemiological stamp peculiar to astrim and give it a place by the side of small-pox, but ey look upon it only as a shoot from the parent stem.

Geographical Origin.

In endeavouring to elucidate the question by invoking storic epidemiology some have perceived two variolic rrents—one, the Asiatic, the oldest known, that of the assic authors since Rhazes, whose streams are to be aced back to its original oriental sources; the other, the rican, a newly-proclaimed bastard offshoot whose world igration was not noticed until the end of the nineteenth ıd the beginning of the present century.

The historical and geographical supports of this dichoto- ous classification are not very solid, though we remember e mummy of the Pharaoh which still shows marks of ıall-pox on its skin. Records of the spread of small-pox e only available from the seventh century onward, but dates back to the earliest times in India and China. One n follow its spread across Europe and its arrival in America ıring the sixteenth century. For the so-called African ıriety of our own times proof of its spread from the Cape America is wanting, though Ribas, as already indicated, ntures the assumption that the contagion reached Bahia om South African ports, with which it is in commercial lation. At the present moment we are witnessing its rriage from the Antilles to Europe, though we have not tained any evidence tracing it to the "mild small-pox" England, still less to that of Switzerland.

Persistence of Epidemic Type.

If, according to the doctrine above stated, alastrim is a aft on the variola stem, it represents the result of a kind of utation of virulence which has reduced it and fixed it into abortive form of its ancestral type: *attenuation*, *degenera- n*, or *involution*. The sources of this degeneration have en sought sometimes in vaccination, sometimes in climate, metimes in race—explanations which the most cursory amination of epidemiological fact is sufficient to demolish. e cannot lose sight of the consideration that the two riolas are not interchangeable, that is to say, that idemiologically one does not see alastrim evolving into ıall-pox, or small-pox into alastrim. The two varieties epidemics are independent one from the other, although ey may be mixed together at one and the same time. ıe may add that the severe small-pox at the present day pears less diffusible; the weaker variety, alastrim, being dowed with large powers of spread.

Into this doctrine, which has the largest number of rtisans, an error may creep, precisely because of the term *mild small-pox*" being adopted. Alastrim cannot be taken erally to justify this description; its picture is dif- ent, and its cutaneous manifestation is not the same, ıce it does not reach the development characteristic of riola. In a mild case of true small-pox there is corre- ondence between the local and general condition; not in alastrim. Nor is the parallel with "*varioloid*" any ore exact, for the same reason, and, moreover, for the rther reason that while varioloid exists as a clinical form epidemic of pure varioloid is unknown.

Analogies.

There are some dissimilar diseases which, on the dis- very of their pathogenic cause, blend into a single entity, and there are some similar diseases which by the same process are split into a bundle of distinct components. Thus typhoid fever is dissociated into typhoid proper and the paratyphoids; relapsing fever dissociates into different varieties, each corresponding to its own spirochæte, or even in some cases to its own agent of transmission. These comparisons have been alluded to already, and I may cite the case of yaws, so like syphilis that the identity of the two was placed in the forefront; the *treponema* has now established alike the difference and the resemblance. These diseases with clinical affinity have, as a rule, causative organisms which are very closely affiliated. How para-variola stands in this respect must be left to the future to show. At the moment we can only recognise a variolic family having small-pox in the centre and alastrim on the flank, followed by cow-pox, then zonal varicella, and, in addition, certain epizootic diseases, such as *clavelée* or sheep-pox. This is but a provisional formula until the Gordian knot of the *alastrim question* has been cut.

One thing at least may be considered certain henceforth; alastrim exists, and is an epidemiological reality. To be convinced one has only to see it in progress.

‡ *Preventive Measures.*—In parenthesis I may observe that it obvious that the principle of compulsory notification should applied as much to alastrim as to small-pox. But in the ıited States, to take one example, it does not appear to me that official practice conforms with the epidemiologic requirements. astrim exists, if not as a proved type, at least as a true epidemic tity. Why, then, exclude it from the list of notifiable infec- ıus diseases and put it under the same heading as small-pox? it because it differs in any way from small-pox from the ministrative point of view? If so, it might perhaps be apler to accommodate to the two points of view by giving designation "variolo-alastrim" official recognition. As gards preventive measures outside the area affected, everything ssible, apart from strict quarantine, should be done. If the easures applied at Ponta-Delgada had been effective, the vasion of alastrim would have been avoided, in the same y as has the importation of variola, in the same port, on veral occasions. Against dissemination within the area, the oral force required to pursue the fight against so feeble an emy is often lacking, and it may be that even sufficient funds not available. This is what happened in the Azores. ıgland and Switzerland know very well what it costs them to rry on their struggle against "mild small-pox" considered as disease to be treated administratively in all respects as small- x, always in the expectation, so far unrealised, of seeing it n into small-pox.

METROPOLITAN HOSPITAL APPEAL.

THE Lord Mayor of London, President of the hospital, is making a special Christmas appeal for £50,000 to build and equip a suitable home for the nursing staff, who are now housed in old and dilapidated cottages adjacent to the hospital. The hospital was founded in 1836 in Devonshire-square in the City, and in 1886 it was transferred to its present site in Kingsland-road, E. Accidents in this neighbourhood are of such frequent occurrence that the present accommodation for these cases is totally inadequate, and it has been decided to add a new casualty ward and receiving office, which will form part of the new building to be erected.

THE DENTAL SURGEONS' DIRECTORY, 1925.

THE Dental Surgeons' Directory[1] makes its appearance for the first time as a separate issue instead of being incorporated with the Medical Directory. The innovation should be appreciated by members of the dental profession to whom this annual volume is so useful, since the information they require is now contained in a handy volume at a moderate price. The number of qualified dental surgeons on the Register is now 5968; at present they are in a minority of those who are entitled to practise dentistry and whose names appear in the Dental Register, but every year the disparity will become less and the Dental Surgeons' Directory will tend to increase in size. The title of the volume is a timely reminder that only qualified dental practitioners have the right to use the title of dental surgeon or surgeon-dentist. In addition to the names of dental surgeons, the volume includes a list of the examining bodies granting dental qualifications, the various dental hospitals and schools, dental societies and journals. Doubtless, future issues will see some addition to this extra matter. Reference might, for instance, have been made to the museum of the Odontological Section of the Royal Society of Medicine which is housed at the Royal College of Surgeons of England, and the times when it is available for inspection. The inclusion, under the heading of Dental Societies, of the Incorporated Dental Society may mislead, for the volume purports to be a record of qualified dental surgeons only, and this society is the bond of registered but unqualified dental practitioners. Under the heading of the University of London there is no mention of the fact that the M.S. can be taken in dental surgery. It is true that so far no candidate has offered himself for the mastership in this subject.

THE MEDICAL YEAR BOOK, 1925.

THE second annual issue of Mr. C. R. Hewitt's Year Book[2] appears just before the end of the expiring year. The reception of the book has been gratifying, and the editor has rewarded his critics and mentors by availing himself of their suggestions in making the new edition better than the first. Among the important additions to the contents are the following: Post-graduate teaching and facilities in Great Britain, London Poor-law hospitals and infirmaries, list of medical officers of health in the Provinces, Wales, and Scotland, List of Coroners, and the Medical Benevolent Societies. Readers might still be glad of some record of the Red Cross clinics at which baths and other forms of physical treatment can be obtained at a moderate figure. We have no doubt that with these additions the year book will maintain its popularity.

CALENDARS AND DIARIES FOR 1925.

A CONVENIENT block calendar for 1925 has been issued by the Anglo-French Drug Co. (238A, Gray's Inn-road, London, W.C. 1). There is provided for each day throughout the year a sheet of white paper four inches square for written memoranda, and the stiff hinged cover provided preserves the privacy of the notes, and yet by means of a window permits the date to be constantly seen. A certain number are available gratis to medical men on application to the company.

A MEDICAL ART CALENDAR.

A MEDICAL Art Calendar for 1925, published by J. Philip Kruseman (The Hague), contains beautiful reproductions of pictures on medical subjects by Gerard de Lairesse, Michel Marie Charles Verlat, Cornelis Troost, Jan Havickz Steen, David Teniers, the younger, and other masters. The horrors of tooth extraction are depicted, perhaps more frequently than we would choose to see them, but the Monkey Dentist and his pathetic patient huddled in a chair (Verlat) gives the necessary warning as to the dangers of postponing our visit to the dentist until only drastic measures are possible without unduly harrowing us.

THE WELLCOME PHOTOGRAPHIC EXPOSURE CALCULATOR HANDBOOK AND DIARY, 1925.

THIS useful little pocket-book for photographers is now so well known that it needs no description as regards its general format, though the present edition contains some new features. These include a concise description of development with the aid of a desensitiser, a process by which the dark room is practically eliminated—a great convenience to tourists and travellers—in addition to a comprehensive list of comparative speeds of development papers and lantern plates. Valuable notes on the various processes of producing a photograph are given, and the exposure calculator is as usual affixed to the inside of the back cover. By posting one of the pages of the book (the price is now 1*s.* 6*d.*) to Messrs. Burroughs, Wellcome and Co., the purchaser is entitled to free photographic advice and literature during the year.

A CONVENIENT MEDICAL VISITING LIST.

A WELL-MADE, compact pocket book, containing much information as well as adequate space for a journal, obstetric and vaccination engagements and memoranda of various descriptions is the form in which Smith's Medical Visiting List is well known to the profession. The 1925 edition marks the seventy-ninth year of its publication; its popularity is thus well established. The 32 preliminary pages are well and clearly printed, though the type is necessarily small, for in these are contained almanacks, tables of heights, weights, expectation of life by various rates of mortality, tables of expenses and of signs useful to practitioners, metric measures, poisons and their antidotes, to give only a few examples of the mass of valuable information offered. Space is found at the end for lists of drugs and instruments wanted and for lists of things lent, with the addresses of the borrower. The book is published by Messrs. Hazell, Watson and Viney, Ltd., 52, Long Acre, London, W.C. 2.

"THE PLU-VEE SUPER NAIL-BRUSH."

THIS brush is ingeniously arranged so that the bristles are always kept short, and therefore stiff, an obvious advantage where the hands and especially the nails may become grimed. The bristles are surrounded by a framework which can be adjusted so that they can be moved upwards as the extremities wear away. Four adjustments are possible, and it is claimed by the manufacturers, the Page-Coyne Co., Campo-lane, Sheffield, that the brush will outlast five ordinary brushes. The price of the brush is 2*s.* 6*d.* and refills can be obtained for 1*s.* each.

E. R. H.—We have received other complaints of this nerve-racking noise.

Narcosis.—The common difficulties and dangers in giving anæsthetics are dealt with in such standard text-books as those of Boyle, Buxton, Hewitt, and Silk, and especially in a little book with the rather misleading title, "Backwaters of Lethe" (H. K. Lewis and Co.), published by the late Dr. E. A. H. Barton in 1920, in which he pilots would-be anæsthetists over the shoals and rapids of narcosis in a readable and scholarly way.

CORRIGENDA.—In the memoir of Prof. John Hunter, by Prof. G. Elliot Smith, which appeared in THE LANCET of Dec. 20th, the reference to the journal in which the fullest account of Hunter's work is given should be *Surgery, Gynecology and Obstetrics*, and in the third paragraph of the first column on page 1306 the dates should read August, *1921*, and February, *1923*.

Special Supplement

TO

THE LANCET

REX v. WALTER ROBERT HADWEN

BEFORE MR. JUSTICE LUSH AND A JURY AT THE GLOUCESTER AUTUMN ASSIZES.

A Synopsis of Contents is given on p. 66.

Monday, October 27th, 1924.

Mr. C. F. VACHELL, K.C., and Mr. ST. JOHN MICKLETHWAIT appeared as Counsel for the Prosecution (instructed by the Director of Public Prosecutions).

Sir EDWARD MARSHALL HALL, K.C., and Mr. A. F. CLEMENTS appeared as Counsel for the Defence (instructed by Messrs. Langley Smith and Sons, Gloucester).

The CLERK OF ASSIZE. Walter Robert Hadwen, you are charged in this Indictment with manslaughter, namely, with unlawfully killing Nellie Christabel Burnham, in the City of Gloucester, on the 10th August in the present year, and you stand charged with the same offence upon the Coroner's inquisition. Are you guilty or not guilty?

The PRISONER. Not guilty.

The Jury were sworn.

The CLERK OF ASSIZE. Members of the Jury, the prisoner at the Bar, Walter Robert Hadwen, is charged in this Indictment with manslaughter, namely, with unlawfully killing Nellie Christabel Burnham, in the City of Gloucester, on the 10th August in the present year, and he stands charged with the same offence upon the Coroner's inquisition. To this Indictment and to this inquisition he has pleaded not guilty, and your duty, therefore, is to inquire whether he be guilty or not guilty and to hearken to the evidence.

OPENING SPEECH FOR THE CROWN.

Mr. VACHELL said: A little girl named Nellie Christabel Burnham died in Gloucester on August 10th last, she then being aged 10 years. She died of diphtheria, and pneumonia which followed upon it. She was attended in that illness by Dr. Hadwen, who stood before the Court charged with manslaughter because the prosecution alleged (and it was for them to prove it) that through his inattention, gross inattention and want of skill or knowledge, or both, he failed to detect the disease from which the child was suffering, and to administer the proper remedy, and that if he had not so grossly failed in his duty as a medical man, in all probability the child would have recovered, and would have been alive now. The Jury would hear from his Lordship what amount of actual negligence rendered a man criminally responsible when death resulted from it.

For his part, Mr. Vachell said, he would content himself by putting before them what he understood to be the law on the subject at the present day, and what it had been for many years, and it was included and covered by these words: "Any person, whether he is a properly qualified medical practitioner or not, who professes to deal with the life or health of others, is bound to have competent skill to perform the task which he holds himself out to perform, and bound to treat his patients with care, attention, and assiduity, and if a patient dies for want thereof he is guilty of manslaughter." In another case it was held that "no one has a right to shorten the life of the human being except by lawful authority, and an acceleration of death by improper medical treatment may be evidence of the criminal offence of manslaughter. There is no discrimination in law between the degrees of most criminal and slightly criminal inattention."

Mr. JUSTICE LUSH (interposing): May I ask you whether in these cases the medical practitioner actually did something and that by some treatment death was accelerated? That is my impression.—Mr. VACHELL: I cannot assist you for the moment, my Lord. I have not the reports. I think we can probably get these in the Law Library here.

It was necessary for him, Mr. Vachell continued, to say something about the disease diphtheria in order that the Jury might be able to follow the evidence on the subject. He proceeded to relate how the disease originated and the various symptoms which the disease set up in the patient. The symptoms, he said, comprised thickness in the speech, a discharge from the nostrils of a yellowish colour, stained with blood, soreness of the throat, and a peculiarly foul breath, and added to that the patient very often became very drowsy. To discover the existence of diphtheria was not for a medical man a very difficult matter, especially if there was membrane in the throat, and any of the symptoms he had mentioned should always tell him that there was a suspicion, at any rate, of the disease. What was perhaps the greatest aid of all in these matters to a medical man, and a procedure which was recognised as being the first step to take in cases that were suspicious of diphtheria, was to procure a swab from the throat of the patient and to have it examined, and then if the diphtheria microbe was discovered when the bacteriologist examined the swab, the discovery, taken in conjunction with the symptoms already described, made it absolutely certain that the patient was suffering from diphtheria. The time was, up to 1896, when diphtheria was looked upon almost as a necessarily fatal disease. The death-rate varied from year to year; sometimes fatal cases would average 30 and 40, and had even reached 60 per cent., amongst those who contracted the disease. Then the discovery was made of what was known as antitoxin, which was a serum injected into the patients with most beneficial results. It was proved now by statistics that the percentage of deaths where antitoxin had been used within the first five days of illness had been reduced to something like 10 per cent., and that where patients had been fortunate enough to receive the treatment on the first day the death-rate was in some years reduced to 3 per cent., and in others actually to nil—every one of the patients recovered. Therefore, there could be no question that this treatment, which was accepted generally by the medical profession, was the proper remedy to apply to the disease, and that it was a remedy which in strong probability would save the patient's life.

This prosecution, Mr. Vachell remarked, is not one brought by any private individual. After the verdict of the Coroner's Jury, which you have heard resulted in a finding against Dr. Hadwen, the papers were placed before the Director of Public Prosecutions, and it is on his behalf that I, with my learned friend, Mr. Clements, am appearing here to-day. The Public Prosecutor, of course, has absolutely no interest at all in this matter, except the hope that justice will be done.

Sir E. MARSHALL HALL. Mr. Vachell has no right to tell this Jury what the Coroner's Jury found.—Mr. VACHELL. The prisoner has been charged upon the Coroner's inquisition.—Mr. JUSTICE LUSH. I don't think any harm has been done.

Mr. VACHELL continued. I was only going to administer a word of caution to you. I expect that you know as much about this case as my learned friend, Sir Edward Marshall Hall, and as much as I do, and I wanted to say that it is the strong desire and hope of the Director of Public Prosecutions and of my learned friend and myself here that you will find your verdict only upon the evidence that you hear now. Of course this case has been discussed throughout the length and breadth of the city, and I have no doubt there have been a great number of things said in the papers about it. I can only hope that none of you have come here with anything like views beforehand, for I am perfectly certain of this: that your plain duty is to base your verdict upon the opinion that you come to, and honestly come to, on the evidence, and leave all other matters that may have been discussed, or that you may have thought of in connexion with this case, entirely outside.

Mr. Vachell then proceeded to review at length the evidence to be called for the prosecution, and commented that Dr. Hadwen in this case never took a swab from the throat of the patient with a view of seeing whether the diphtheria microbe was there or not; yet, he submitted, here was a case of the most highly suspicious character in view of all the surrounding circumstances. There was one happening to which, perhaps, the defence would attach some importance, that was that on one occasion the little girl, while the mother was away from the house, came downstairs to fetch some water. He (counsel) rather gathered that the suggestion would be made that the child then caught pneumonia and that it was pneumonia which caused her death.

Sir E. MARSHALL HALL (interposing). That she caught a chill, which developed into pneumonia.

Mr. VACHELL. My learned friend puts it more correctly, perhaps, but I think it all comes to the same thing. The post-mortem examination, he continued, showed death to be due to diphtheria and pneumonia. If the child did contract pneumonia and died from that independent of anything whatever to do with the diphtheria there was nothing that could be laid to the charge of Dr. Hadwen. But the evidence he was about to call would establish that the pneumonia was of that sort which followed and was a sequel to diphtheria. They knew Dr. Hadwen, concluded counsel, as a gentleman of position in the city, and a justice of the peace. Still, if the evidence satisfied the Jury that he had been grossly negligent, little caring what attention he paid to the case, and that, in consequence of that negligence, the child's life had probably been sacrificed, then, much as they might regret it, it would be their duty to find him guilty.

EVIDENCE FOR THE CROWN.

ANN MARIA BURNHAM, *sworn*.

Examined by Mr. MICKLETHWAIT.

Are you the wife of George Burnham?—Yes.

Is your husband a steel presser?—Yes.

You live at 49, Vauxhall-road, Gloucester?—Yes.

Had you a daughter, Nellie Christabel?—Yes.

Was she ten years of age?—Yes.

And did she live at home?—Yes.

What was her general condition of health?—Very good.

When was she taken ill?—On the 30th July.

What did she complain of?—She complained of headache.

What did you do?—I kept her in bed all day Thursday and she did not seem to get any better; she began to talk very thickly towards night. I sent for the doctor the following morning on the 1st August.

What time did he come?—About half-past ten.

He was your club doctor, I think?—Yes.

What did he do when he came?—He looked down her throat and he looked at her back and chest to see if she had any rash.

How did he look down her throat?—Put his two fingers in her mouth.

Mr. JUSTICE LUSH. Then you say he looked at her back and chest?—Yes, to see if she had any rash, because he said it looked like scarlet fever.

You mean he said that after examining her chest or before?—Before.

Mr. MICKLETHWAIT. When he looked down her throat, where was she?—In bed.

Lying in bed?—Yes.

Did he use any sort of light or anything to enable him to see?—No, nothing at all.

Or did he use any instrument to put her tongue down?—No.

Did he tap her chest?—No.

Did you see whether he felt her pulse?—No.

On this first occasion?—No.

Mr. JUSTICE LUSH. Are you sure he did not or what?—He did not.

Mr. MICKLETHWAIT. Did he prescribe anything?—Medicine. He told me to let her gargle her throat with vinegar and warm water.

Was that all he said or was anything else said?—No, give her medicine; I was to send to the surgery at night for a bottle of medicine.

How long was he there?—About three minutes.

At that time was there anything noticeable about your daughter?—Yes, the smell was very bad and the discharge.

What was the discharge?—Yellow.

Where from?—From the nose.

What smell are you referring to?—Her breath.

Then where was the discharge from, her nose?—Yes.

What was the nature of that?—Yellow, but it was tinged with blood.

Mr. JUSTICE LUSH. Do you say that that yellow discharge tinged with blood occurred while the doctor was there or before he came or after he had been?—Just after she was taken ill on Saturday.

That was on the 30th?—On the next day.

On the 31st?—Yes.

Mr. MICKLETHWAIT. Was it noticeable when the doctor was there or not, the discharge?—Yes, most every time, because she was always sleeping, but if she was awake that was the first thing she would do, feel for her handkerchief.

Mr. JUSTICE LUSH. The question is was that yellow discharge there when he came?—Yes, it was always there when he came.

Mr. MICKLETHWAIT. Did you say anything to the doctor about any of these things you have spoken to us about, did you mention any of them?—He was always there.

No, did you say anything?—Yes, I know I mentioned it.

What did you mention to him?—I told him about Gladys's breath being the same as this little girl's, the same smell.

Mr. JUSTICE LUSH. Her breath?—Yes.

Mr. MICKLETHWAIT. Gladys was another little daughter of yours?—Yes.

You said that Gladys's breath was the same as Nellie's, who was in bed?—Yes.

When did you say that?—I said that on the Monday.

Mr. JUSTICE LUSH. Was Monday the 1st?

Mr. MICKLETHWAIT. No, this was the Friday.

Mr. JUSTICE LUSH. Let us try and keep to the dates.

Mr. MICKLETHWAIT. I am trying to get from you what happened on the Friday. Did you tell him anything on the Friday about any of these things; did you draw his attention to any of them?—I told him it was the same as Leonard, the same smell and all.

The same smell as Leonard?—Yes.

He had been ill before?—Yes.

And Dr. Hadwen had attended him?—Yes.

Mr. JUSTICE LUSH. It is important that we should get the dates right. The first time you saw the doctor was on the 1st August?—Yes, on the Friday.

On that day did you say anything to him about the breath or anything else? If you cannot recollect say so, but you told us just now it was on the Monday you said that.

Mr. MICKLETHWAIT. That is about Gladys?—I told him on the Monday.

Did you say anything to him on the Friday?—I could not say now. Of course, it did not want finding out; it was so strong.

When did you tell him about Leonard?—On the Monday, and I told him about the little girl.

Mr. JUSTICH LUSH. I thought the date Mr. Vachell gave us of the second visit was the 4th August; that would not be a Monday, would it?

Mr. MICKLETHWAIT. Yes, that is Monday. Friday was the 1st. (To the Witness.) You said something about your daughter being drowsy?—Yes.

Was she drowsy on the first occasion when he came?—Yes.

Then he went away and did you get the medicine and the gargle and so on?—Yes.

When did the doctor come again?—On the Wednesday, the 6th.

When did he come after the Friday?—On the Monday.

That is the 4th?—Yes.

What was the state of your daughter then?—She was no better.

What were her symptoms; what was there to see?—Very flushed.

What about her breath?—Her breath was very bad.

And was there any discharge?—Yes.

Of the same kind as before or not?—Yes.

What did the doctor do?—He looked down her throat.

In the same way as before, with his fingers?—Yes, in the same way. He asked if she was going on with the gargle and if she was taking her medicine.

Did you tell him anything then; was she taking her medicine?—I told him she could not gargle very well; she could not gargle so well as the lad.

Did he feel her pulse?—No.

Or take her temperature?—No.

How long did he stay?—It was no longer than the three minutes. I do not know, it was hardly as long that morning.

That is the Monday, the 4th. When did he come next?—On the 6th, Wednesday.

What was her condition then?—She was weaker.

Was the smell the same or was it different?—No, it was a bit stronger.

Was there any discharge?—Yes, it was very bad that day.

Did you notice anything specially about her on that day?—Yes, that was the day I pointed this out in her nostrils.

What did you point out?—It was yellow and it looked exactly like she had in her throat what she had down her nostrils.

Exactly like what?—What was in her throat.

What was that?—To me it looked like sponge.

What colour?—Yellow.

You had seen that in her throat?—Yes.

When did you see it in her throat first?—On the first day the doctor came.

Mr. JUSTICE LUSH. On the first occasion?—Yes.

Mr. MICKLETHWAIT. You say you pointed out to the doctor on this occasion something in her nose, the same sort of yellow stuff?—Yes.

What did you say?—I pointed it out to the doctor and he only said "Oh yes, yes." He did not say I had to do anything for it.

He did not tell you to do anything with it?—No.

Then did the doctor tell you on that occasion what to do?—He asked if she could gargle, and I told him she could not get on with the gargle very well, and he said I was to paint her throat with glycerine with a feather.

That was on the Wednesday?—Yes.

You have told us about this yellow substance; when did it go away?—On the Thursday. It came on the Tuesday and it went gradually by the Thursday.

How did it go?—I used to get the girl to bathe it with a hot rag to her nose.

With anything on it?—Warm water with boracic.

Mr. JUSTICE LUSH. Did you apply the hot rag?—Yes.

Did the doctor tell you to?—No.

Mr. MICKLETHWAIT. Would it not wipe away?—No.

That, you say, took place on the 7th?—On the 6th.

But you took this stuff away on the Thursday?—It gradually got less.

When did you begin wiping it away?—On the Wednesday.

Mr. JUSTICE LUSH. What are the days of the month?

Mr. MICKLETHWAIT. The 6th is the Wednesday, that is when the doctor came and she started putting this on the nose. (To the Witness.) Then you say it went away on the next day, the 7th?—Yes.

Mr. JUSTICE LUSH. Was he there longer on this visit on the 6th?—No, about the same time.

Mr. MICKLETHWAIT. Did your daughter get better or worse?—She gradually got weaker.

When did he come next?—On the Saturday, the 9th.

Did he come of his own accord or did you send for him?—I sent for him, but he said he was coming that day if I had not sent for him.

Mr. JUSTICE LUSH. On the other dates did he come of his own accord or did you send for him?—Yes; I only sent for him the first day he came.

Mr. MICKLETHWAIT. What time did he come?—About the same time in the morning, about half-past ten.

What was your daughter's condition then?—Very weak that morning.

What about the breath?—The breath was very bad. She could not speak. If you spoke to her she could not answer.

Was there a discharge?—Yes.

The same kind of discharge that you have told us about?—Yes.

What did you say to Dr. Hadwen when he came?—I told him the little girl seemed very ill and I thought she had bronchitis. He said, "Probably, these throats sometimes lead to paralysis."

What did he do?—He looked down her throat, felt her pulse, and he sounded her chest.

With an instrument?—Yes.

Mr. JUSTICE LUSH. Did he take her temperature?—No.

Mr. Micklethwait. Did he say anything ?—He said her throat was clearing nicely ; there was scarcely anything the matter with her, she would soon be all right and I was to give her plenty of cold milk.

Did he ever what is called take a swab of the throat ?—No.

Mr. Micklethwait. I asked whether he took a swab at any time.

Mr. Justice Lush. She said no.

Mr. Micklethwait. She said no. What was it he prescribed—I am not sure I caught it—for your daughter to gargle with ?—Vinegar and warm water.

At one of the visits did he also prescribe a tonic ?—Yes.

When was that ?—On the 6th.

Mr. Justice Lush. He had prescribed some medicine on the 1st ?—Yes, a bottle of medicine on the 1st.

Mr. Micklethwait. Then he prescribed the tonic afterwards ?—Yes.

And did you say something at this visit on the 9th about the tonic ?—On the Saturday morning I told the doctor she could not keep it down.

What did he say ?—He said I was to dilute it with a drop of water.

How long was he there on that visit ?—About five minutes.

You say she could not keep down the tonic. When did she first vomit ?—On the Friday. She could not keep anything down on the Friday.

That is the 8th. You have told us about the 9th. Was the breath smelling just as badly ?—Yes.

And the discharge the same ?—Yes.

Was she still drowsy and lying in bed and very weak ?—Yes.

Did Dr. Hadwen say anything to you about being careful to keep her warm ?—No, he did not say anything whatever.

Or to keep her from sitting up ?—No.

At any time ?—No.

Mr. Justice Lush. Did you tell him she had been in bed all these days ?—No. She was always in bed ; she was in bed all the time.

Did she say anything at all as to whether she might get up or stop in bed ?—No.

Nothing ?—Nothing.

Mr. Micklethwait. On the 6th August he told you to paint the throat with glycerine ?—Yes.

Did he give any reason for it do you remember ?—Because I told him she could not gargle very well.

Mr. Justice Lush. Members of the Jury, I need scarcely warn you, but you will not, I am sure, allow anybody to speak to you about this case while it is going on at all.

(*Adjourned for a short time.*)

Mr. Micklethwait. You have told me about the time Dr. Hadwen came on Saturday, the 9th ?—Yes.

After that did you have a consultation with, I think, your brother-in-law, Mr. Fudge, and some other relation ?—Yes.

As a result, was it decided to call in another doctor ?—Yes.

And did Dr. Ellis come in on the evening of the 9th ?—Yes.

What time did he come ?—Just after ten.

What did he do when he came ?—He examined the little girl and took her temperature.

Sir Edward Marshall Hall. I do not think anything that Dr. Ellis said would be evidence-in-chief.

Mr. Justice Lush. No, but what he did would be.

Mr. Micklethwait. I was on what he did. He took her temperature ?—Yes. He took a swab of her throat. He examined her chest and tapped her chest and back.

In what condition was your daughter then ?—Very weak.

Did you think she was likely to recover then or not from what you saw ?—I did not know what to think.

Then I think she got worse and died, was it about ten minutes to one ?—Yes.

Did you wash the little girl's clothes after her death ?—Yes, on the Monday.

Do you remember noticing anything when you did that ?—Yes, in the bottom of the bath.

What was it ?—It was a bit of yellow like I had seen in the child's throat. I knew what it was when I saw it.

Where was this piece of yellow ?—In the water in the bath.

What sort of yellow stuff was it ?—It looked to me like chewed tissue paper.

About how big ?—About 1½ inches I should think in length.

What sort of shape ?—Just curved round a little.

You have told us before that your other children were taken ill ?—Yes.

When was the boy, Leonard, taken ill ?—In July, I forget the dates.

Mr. Justice Lush. What was in July ?—The little boy's illness.

Was that before this child's ?—Yes.

Mr. Micklethwait. Were his symptoms similar to Nellie's or not ?—Yes.

Was there the same smell ?—Yes.

And the same discharge ?—Yes.

And did Dr. Hadwen attend him ?—Yes.

On how many occasions ?—Four.

Mr. Justice Lush. We ought to know, I suppose, whether that was before or during the time this child was ill ?—Just three weeks before.

Did that boy get well ?—Yes, he is better. He is well now.

Sir Edward Marshall Hall. Your Lordship will make a note of his name, Leonard, because I shall have to ask a question about him.

Mr. Micklethwait. Do you say it began three weeks before ?—Yes, just three weeks to the day the little girl died.

Mr. Justice Lush. What I understood you to say to me was that Dr. Hadwen attended this boy three or four times before your little girl was taken ill.—Yes, before Nellie was taken ill.

Mr. Micklethwait. I wanted to know when Leonard's illness began and she said three weeks before Nellie died.—Yes, that is right.

Sir Edward Marshall Hall. I can give your Lordship the dates, the 21st, 22nd, 23rd, 25th, and 28th of July.

Mr. Vachell. Those are the attendances.

Sir Edward Marshall Hall. Yes.

Mr. Vachell. Yes ; it would be the 19th he was taken ill.

Mr. Justice Lush. Did the little boy have similar discharges ?—Yes.

Was he drowsy ?—Yes.

And the doctor treated him successfully ?—Yes.

Mr. Micklethwait. Did you draw the attention of the doctor on any occasion to these symptoms ?—I do not remember, because they were all there so plain I did not think he wanted his attention drawn to them.

Did you say anything about the breath and the discharge ?—Yes, I told him what a nasty smell it was.

Mr. Justice Lush. That is in the boy's case ?—Yes, the little boy, Leonard.

Mr. Micklethwait. Do you say he got better ?—Yes, he got better.

Do you remember anything happening before he got better ?—Yes, he brought up something on the Thursday night. I had been giving him slices of lemon and sugar and he brought up something out of his throat.

Sir Edward Marshall Hall. I do not want to object, but I very much doubt whether this is evidence.

Mr. Justice Lush. I do not know where it may lead us.

Sir Edward Marshall Hall. I have not objected before because I am going to ask questions in cross-examination.

Mr. Justice Lush. We have quite enough to do to attend to this case.

Mr. Micklethwait. Exactly. It is only, of course, material if it is said this is not diphtheria at all.

Sir Edward Marshall Hall. That is not the point. The point is whether Dr. Hadwen thought it was diphtheria or not.

Mr. Micklethwait. You had a daughter named Gladys ?—Yes.

Was she taken ill ?—Yes.

Mr. Justice Lush. When was that ?

Mr. Micklethwait. When was she taken ill ?—In the early part of the week, the same week as Nellie.

Mr. Justice Lush. Before Nellie died ?—Yes, the same week as Nellie was took ill, the early part of the week.

Mr. Micklethwait. And was she sent to the hospital ?—Not till after the little girl died.

Did Dr. Hadwen attend her ?—I took the little girl Gladys to his surgery.

Mr. Justice Lush. The question was, Did Dr. Hadwen attend her ?

Mr. Micklethwait. You mean to Dr. Hadwen's surgery ?—Yes.

Sir Edward Marshall Hall. That was before the girl died ?—On the Tuesday before the other little girl was taken ill, towards the early part of the week. It was the 28th or 29th of July.

Mr. Micklethwait. Were her symptoms similar to these symptoms of Nellie's ?—Yes, only she was not quite as ill as Nellie was.

And after Nellie died, she was taken to the hospital ?—Yes.

Did she play with a little girl called Olive Cornock ?—Yes.

When was she playing about with her ?—She always did come over to the door and play ; she had been playing for a week or two.

They were always playing about together ?—Yes.

Had you another daughter, Hilda ?—Yes.

Was she taken ill ?—Yes.

I think she was not attended by Dr. Hadwen at all ?—No.

When was she taken ill ?—The same day that Nellie died.

That is on the 10th. Were her symptoms similar to those of Nellie ?—Yes.

And was she taken to the hospital ?—Yes, she was taken off on the 11th.

Did you leave your house one evening ?—Yes.

Do you remember which evening it was ?—Yes, on the 7th.

That is the Thursday ?—On the Thursday evening.

How long were you out of the house ?—About ten minutes.

When you went what time was it ?—About 9 o'clock.

9 o'clock in the evening ?—Yes.

When you went away was your little girl Nellie in bed ?—Yes, she was dozing. We had only just come down the stairs ; me and the little boy, Leonard, had been sitting up there all the evening and I had just got her to sleep. I left her in her bed and I come straight down stairs.

And did you leave your little boy, Leonard, in the house ?—Yes, he was down in the kitchen.

Is there any carpet on your stairs ?—Yes.

Is there carpet in the bedroom where she was ?—Yes, on the side of the bed.

Is there a carpet on the stairs ?—Yes.

What was there in the kitchen ?—Linoleum over the floor and a rug.

Then is there a back kitchen with some water in it ?—Yes.

A sink ?—Yes.

What is the floor of the back kitchen ?—Blue tiles, blue bricks.

Had you ever known a case of diphtheria before ?—No.

Cross-examined by Sir Edward Marshall Hall.

You were very fond of this little girl of yours naturally ?—Yes.

And her death was a dreadful grievous blow to you ?—Yes, it was.

Did you ever suspect that your little child was suffering from diphtheria while she was ill ?—No, I cannot say I did, only what a neighbour told me on the Monday and I said the doctor ought to know.

The neighbour told you on the Monday ?—Yes.

Was that the Monday after she died or before ?—Before she died.

Mr. Justice Lush. That is on the 4th ?

Sir Edward Marshall Hall. Yes, the 4th. A neighbour told you on the Monday ?—Yes.

Did you suspect it was diphtheria ?—No, it was the same as the little boy, Leonard, and I thought the doctor ought to know.

Would it be true to say that you thought from the first it was a case of diphtheria because of the stench of the breath ? Would it be true to say this, " I thought from the first it was a case of diphtheria because of the stench of the breath ?"—I do not know as I did say it.

If you did say it, would it be true ?—No, because I never thought it was.

Why did you say it ?—I do not know I did say it.

Mr. Justice Lush. Where is that ?

Sir Edward Marshall Hall. Before the Coroner. (To the Witness.) You were examined before the Coroner on the 12th August while this matter was quite fresh in your mind and I want to call attention to something you did say and things you did not say.

Mr. Vachell. I am sure my friend wants to be quite fair. I think my friend is under a misapprehension. She said, if your Lordship will refer to the depositions——

Sir Edward Marshall Hall. Please do not put this into the witness's mind.

Mr. Vachell. I will refer his Lordship to the depositions.

Sir Edward Marshall Hall. If your Lordship will look at it and not read it aloud. It is right at the very end. (To the Witness.) Did you ever consult Dr. Hadwen about your daughter Hilda at all ?—No.

When you said this before the Magistrates, " I thought from the first it was a case of diphtheria because of the stench, but I did not mention the word diphtheria to Dr. Hadwen or he to me," were you speaking about Nellie's illness then ?—No, I do not remember saying it.

Did you ever consult Dr. Hadwen about Hilda ?—No.

Did you ever consult Dr. Hadwen about anybody except Nellie, Gladys, and Leonard, the three ? Did you say this, " I did not mention the word diphtheria to Dr. Hadwen or he to me. I thought he knew better than I did " ?—Yes, I did say that.

Then you did say that ?—Said them words.

Was that in reference to Nellie's illness ?—Yes, it was.

Why did you say that you had thought from the first it was a case of diphtheria because of the stench in the throat ?

Mr. Vachell. I do not like to interrupt my friend, but would not it be better to put the whole of what she said ?

Mr. Justice Lush. The whole of what she said in that connexion. I thought that was the whole of what she said.

Mr. Vachell. Will your Lordship refer to it ?

Sir Edward Marshall Hall. I will read the paragraph my friend wants me to put which I have dealt with. " I have a child named Hilda, aged 18 years now." Then it goes on, " I thought from the first it was a case of diphtheria because of the stench of the breath." That was never asked about Hilda. The next question was asked about Nellie.

Mr. Justice Lush. I think it must be.

Sir Edward Marshall Hall. I want to know why, just now when I asked you if you had suspected diphtheria, did you say you had never suspected diphtheria till your friend told you on the Monday ?—Because I had never seen a case of diphtheria.

Is it true you did suspect diphtheria or did you not suspect diphtheria ?—I do not think I did or else I should not have let it run on so long.

Then that answer is inaccurate ; I make no more comment about it. Why did you never tell the Coroner, when you gave your evidence before him about two days after the little girl died, that you had seen anything in the child's throat ?—Because I was never asked the question.

Were you asked it before the Magistrates ?—Yes.

What you said before the Magistrates was, "I pointed out that she had a yellow substance coming from her nose. He said, 'Yes, yes,' as though he expected to see it. He did nothing else but look down her throat. I saw the yellow substance in my daughter's throat every time Dr. Hadwen looked down her throat." That is what you said before the Magistrates ?—So I did.

But during the whole of your evidence before the Coroner you never said a word about it ?—I never. I could not think of all of it the first day.

When did you get to know ?—I had time to sit and think after.

When did you get to know that it was very important in connexion with this case whether there was anything of that sort in your child's throat or not ? When did you first know that ?—The first day Dr. Hadwen came I saw it in her throat.

When did you know that it was important, in view of this charge against Dr. Hadwen, to say whether there was this stuff in the throat or not ?

Mr. JUSTICE LUSH. Do you understand the question ?—No, I do not.

Sir EDWARD MARSHALL HALL. Do you understand it ?—No, I do not.

I will come back to it in another way. You sent for Dr. Ellis on the 9th August ?—Yes.

At what time did you send for him, about the time ?—Something between nine and ten at night.

Did Dr. Ellis come at once ?—Yes, he was there just after ten.

Who was it suggested Dr. Ellis's name ?—My brother-in-law.

Mr. Fudge ?—Yes.

Did you know that there had been a very acrimonious dispute in the public press between Dr. Ellis and Dr. Hadwen ?—No, I did not. I did not know anything about that business.

Did you tell Dr. Ellis when he came that Dr. Hadwen had seen the little girl that morning ?—Yes.

Did you suggest that he and Dr. Hadwen should see the child together ?—No.

Had you any intention that Dr. Hadwen should see the child that night ?—No.

Dr. Ellis came and he was there two hours, I understand ?—Yes, a long time I know.

He came about half past ten ; he went away after about an hour, did not he, and then came back again ?—Yes.

And he did an operation on her side just there (indicating) ?—I did not see the operation ; I was not there then.

Did Dr. Ellis tell you that night that he knew Dr. Hadwen ?—No, he did not mention Dr. Hadwen.

Was Dr. Ellis told that Dr. Hadwen had been attending the child ?—Yes.

And did Dr. Ellis tell you that night that this child had died by reason of the neglect of Dr. Hadwen ?—I do not know that he did.

Did Dr. Ellis lead you to believe that if he had attended the child the child would have lived ?—I cannot say he did.

Come ; did he tell you or lead you to believe that the death of that child was due to Dr. Hadwen that night ; I have a reason for asking this question and a very important reason. Did Dr. Ellis, either by word or action, lead you to believe that night that but for Dr. Hadwen your child would have been alive ?—I do not remember.

Mr. JUSTICE LUSH. You must try and think. I suppose Dr. Ellis was told that Dr. Hadwen had attended Nellie ?—Yes.

Sir EDWARD MARSHALL HALL. Did he ask how many times he had been ?—No, I do not think he did.

Did he ask what he had done ?—No, I was not up in the room all the time.

Mr. Fudge was there, was he ?—Yes.

Did not you tell Dr. Ellis what Dr. Hadwen had done and had not ?—Yes, I told him when he came at night what he had said about the little girl, that there was scarcely anything the matter.

You told Dr. Ellis that Dr. Hadwen had said there was scarcely anything the matter with her ?—Yes.

Dr. Ellis realised that the child was dying, did he not ?—Yes.

Were you in the room when Dr. Ellis took a swab ?—Yes.

How long was Dr. Ellis away ?—I could not say ; not long.

Was Dr. Ellis told that the child was dead ?—Yes.

Directly after the child died ?—The next morning, on the Sunday morning.

Do you happen to know whether Dr. Hadwen was ever told that the child was dead ?—I do not know I am sure.

You never told him ?—No.

You left everything to Dr. Ellis ?—I do not know that I left it to anyone. I did not go and tell Dr. Hadwen.

Did Dr. Ellis give a certificate of death ?—No.

Did you ask him for one ? —I did not wish for one.

Mr. JUSTICE LUSH. Why not ?—Because I was not satisfied with the treatment the child had had ; I wanted to see justice was done.

Sir EDWARD MARSHALL HALL. Would it be true to say Dr. Ellis was ready to give a certificate of death ?—Yes.

But you did not wish for one ?—No.

You did not want a certificate of death ; you wanted an inquest ?—Yes.

You wanted an inquest because you thought that Dr. Hadwen was responsible for your child's death ?—Yes, so he was.

That was entirely on your own view ?—Yes, my own view.

Did Dr. Ellis ever ask you whether he should tell Dr. Hadwen that the child was dead ?—I do not know ; I do not think he did.

Do you think it was quite fair not to tell Dr. Hadwen the child was dead ?—Yes.

You knew there was going to be a post mortem on this little child ?—Yes.

In order to find out if possible from what the child had died ?—Yes.

Even as the mother of the child, do you think it would have been fair, having made up your mind, as you have told us, about Dr. Hadwen, that Dr. Hadwen should have an opportunity of being present at the post mortem ?—I do not know I am sure ; I do not understand the doctor's business.

It is quite simple. You had made up your mind that Dr. Hadwen was responsible for your child's death. You would not take a certificate ; you did not want one ; you wanted an inquest and you knew there was going to be an examination. Do not you think it would have been fair that Dr. Hadwen should have been told of it ?—I did not understand about that ; I had more trouble than that to think about.

Let us deal with Leonard. He was taken ill about the 20th July, was he not ?—About that time, I am not sure of the date.

And he had exactly the same sort of throat that Nellie had ?—Yes.

And did Dr. Hadwen come to see him and give him medicine ?—Yes.

And also a gargle of vinegar and hot water ?—Yes.

And later on a tonic ?—Yes.

And he attended him on the 21st, 22nd, and 23rd July and on the 25th and 28th ?—No, he only came four times ; he did not come on the 25th.

You say four anyhow, and I suggest five, but he came four times and when he left on the last visit, was the boy practically well ?—No, he was not ; he was in bed.

Was the throat practically well ?—No, he said it was clear.

Did you ever give the boy any more medicine after the tonic ?—Yes, I took him to Dr. Graham.

Surely the boy got quite well ?—He did not get quite well.

Did not you actually leave the sick girl, Nellie, in charge of Leonard on the night of the 7th ?—Yes.

Leonard was well enough to be looking after Nellie ?—I do not know about looking after her, he was there in the house if she shouted to ask for anything.

I can quite understand your feeling in the matter, but remember we are trying this man on a charge of manslaughter. Do try and be fair. Was not Leonard quite cured by, at any rate, the 1st and 2nd of August ?—No, he was not. I do not know that he is as well now as the other two children who went to the hospital.

Mr. JUSTICE LUSH. Was he still in bed on the 2nd ? The doctor had left off coming by the 1st August ?—Yes.

Was the boy in bed still ?—On the last morning the doctor came he was in bed.

I asked later than that; was he in bed at the beginning of August when Nellie was taken bad ?—No.

Sir EDWARD MARSHALL HALL. When the doctor came to see Nellie on the first occasion, was not Leonard up and about ?—Yes, he told me on the Monday when I fetched the tonic I was to let him out.

Will you please speak a little less fast. We are not complaining, because we all realise your feelings. Will you answer this question : So far as you could judge, were Leonard's symptoms identical with the symptoms of Nellie ?—Yes.

The next thing that happened was before Nellie was taken ill that you took Gladys round to the surgery, did not you ?—Yes.

And did he examine her throat ?—No.

I put it to you that he examined her throat ?—He did not.

And he prescribed for it the same gargle that Leonard had had ?—He did not say anything about a gargle, but the same medicine, and the little girl would not open her mouth for him to look down.

Did she complain ?—She felt sick.

Mr. JUSTICE LUSH. Do you say that Dr. Hadwen did not examine her ?—He did not see into the child's mouth because the child would not open her lips.

Sir EDWARD MARSHALL HALL. Did you tell him that the child had got the same throat that Leonard had ?—I did not know she had the same throat; I told him she talked thickly.

And the same smell ?—Yes, and very flushed.

And did you think she had exactly the same illness as Leonard ?—Yes.

May I take it you told that to the doctor ?—Yes, I told him when I took her.

You told him that Gladys was the same as Leonard, and he prescribed ?—Yes, and a little bottle of medicine.

And did he tell you to use the gargle of vinegar and water ?—No, he did not; he said she would be all right when the fever left her.

That was on the 28th ?—No, on the Tuesday.

Did you ever ask Dr. Hadwen to see that child again ?—No, I told Dr. Hadwen when he came to see Nellie she had the same nasty smell.

Mr. JUSTICE LUSH. Did you ask the doctor to see the child again ?—No; she always ran away when the doctor came; I told him she had the same smell, but he never asked to see her or made any answer.

Sir EDWARD MARSHALL HALL. I understand you to complain that Dr. Hadwen only came on the 1st, the 4th, the 6th, and 9th to see Nellie ?—Yes.

Your complaint is that that was not often enough ? No, it was not.

Do you belong to this Vauxhall Industrial Medical Aid Society ?—Yes.

Did you choose to belong to it yourself ?—Yes.

Instead of going on the panel ?—I thought it was handy, because there was somebody calling for the money.

You pay 2*d.* a week ?—6*d.* a week.

For all of you ?—Yes.

Do you know that the Medical Officer of that Society is Dr. Hadwen ?—Yes.

You knew that when you chose to go on the Club ?—Yes.

You complain that he only came four times. Except for the occasion when you sent for him on the Saturday morning, did you ever send for Dr. Hadwen at all, except the first occasion and on the morning of the 9th ?—I sent for him on the 1st.

On the 1st and the 9th ?—Yes.

Those are the only two times you sent for him ?—Yes.

Is it a rule of the Club that in a case of sudden emergency a patient may send at any time, and will receive attention as early as possible ?—I believe so.

Why, if you thought this child was so ill, did you not send for Dr. Hadwen ?—I thought he would call; he could see how ill the child was when he was there. I should think it was his place to come without being sent for every time.

Do you see the effect of that answer. I suggest to you that Nellie was not so ill until you sent urgently on the Saturday morning ?—She got worse every day; she did not improve at all.

Just follow what happens. On the 1st August you sent for Dr. Hadwen because Nellie was ill, and Dr. Hadwen came. You say he only stayed three minutes; I will deal with that in a minute. He came again on the 4th, and you did not send for him until the morning of Saturday the 9th ?—He came on the 6th.

But you never sent for him on the 7th or the 8th; that is the time you say he neglected ?—Yes.

When did you first know that your little girl had been down in her nightdress and her bare feet into the scullery to get water ?—On the same night.

That was on the 7th ?—Yes.

And it was after that, on the morning of the 8th that you saw the first vomiting ?—Yes.

Sir EDWARD MARSHALL HALL. I hope your Lordship will make a note of that; it is of vital importance in this case. Why, when you found your child vomiting on the morning of the Thursday —— ?—It was not on the Thursday; it was on the Friday.

Why, when you saw your child vomiting on the Friday morning, and knew that she had been down in her bare feet on this tiled floor, did not you send for Dr. Hadwen at once, and say, "There is a different symptom which has arisen" ?—Because I expected him to call.

I put it to you in all seriousness that if you had sent for Dr. Hadwen on the morning of the Friday when the vomiting commenced, you might have saved your child's life ?—He would not have done more than he did for her. He would have had to have done more than ever he had done before.

Mr. JUSTICE LUSH: Is that why you did not send for him ?—Yes, I expected him to call. He could see when I pointed out the nose how ill she was, and no doctor needs sending for after that.

Sir EDWARD MARSHALL HALL. Do you know a man named Tanner ?—Yes, I did.

Is he an honest respectable man as far as you know ?—I do not know; I could not say.

Do you know his wife Agnes ?—Yes.

Do you know them both ?—Yes.

Did you hear Tanner give his evidence before the Coroner ?—Yes.

Sir EDWARD MARSHALL HALL. Let us see what he said.

Mr. VACHELL. One moment; is my learned friend entitled to put this question. To read a deposition of somebody else ?

Sir EDWARD MARSHALL HALL. I am not reading a deposition.

Mr. VACHELL. My learned friend said, "Let us see what he said before the Coroner." My friend may call Tanner if he likes, but he cannot do more, because

Tanner could then be cross-examined if this is relevant. I do not know exactly to what my friend refers, but what I am submitting is that my friend should not read it.

Mr. Justice Lush. I quite appreciate your point. I do not see, Sir Edward, how you can get in the evidence of the witness.

Sir Edward Marshall Hall. I am not attempting to get it in, if my friend would only wait. I am perfectly entitled to cross-examine this lady as to whether she heard something said. I do not put it to her as a deposition.

Mr. Justice Lush. In Court, as a witness ?

Sir Edward Marshall Hall. Yes.

Mr. Justice Lush. Is not that utilising the evidence he gave ?

Sir Edward Marshall Hall. In cross-examination that is permissible.

Mr. Justice Lush. Can you do that ?

Sir Edward Marshall Hall. I have done it, I am afraid, hundreds of times. I cannot conceive that it cannot be put in cross-examination. I am going to suggest that this lady said something to Tanner. I will found it in that way.

Mr. Justice Lush. If you put it in that way, it is not open to any objection.

Mr. Vachell. Your Lordship sees what it leads to ?

Sir Edward Marshall Hall. Really ; my learned friend is appearing for the Crown in this case.

Mr. Vachell. If my learned friend is right, without putting any witness into the box at all who can be cross-examined before this Jury, he can say to a witness : " Were you present at the inquest ?—(A.) Yes. (Q.) Did you hear the witnesses examined on behalf of the Defendant ?—(A.) Yes. (Q.) Did they say this ? "

Mr. Justice Lush. I have already said that I do not think that can be done, but I understood that Sir Edward was going to put to the witness : " Is not it the fact that you said so and so to Tanner ? " or " Tanner said so and so to you ? " I cannot possibly prevent that.

Mr. Vachell. That I could not object to, but that, I think, is hardly what my friend proposes to do.

Mr. Justice Lush. That is what I understood.

Mr. Vachell. Then whether it was said at the inquest or not is immaterial ?

Mr. Justice Lush. Quite.

Sir Edward Marshall Hall. I would like to remind my friend that this is not a civil action in a nisi prius Court ; this is a Crown prosecution. (To the Witness.) Do you know George Henry Tanner ?—Yes.

Does he live at 44, Vauxhall-road, and is he a painter and paper-hanger ?—Yes.

Did you see him on the 6th August ?—No, I did not.

Did you tell him this on the 6th August : " The doctor has been this morning, and the child is much better " ?—No, I did not see Mr. Tanner.

Did you see him on the night the child had been to the scullery ?—No, I did not.

Did you see them the following night ?—No.

Did you have a conversation with them about the child having gone to the scullery for water ?—She asked me that a week or two after. She sent for something to be cut out. I knew that they were asked by certain friends that were going there. I knew what was going on ; I knew they were trying to get evidence. It was the night she sent for me to cut her little boy's shirt out. I know ; I have had some friends invite me to tea and something else.

Your suggestion is that Tanner and his wife set a trap for you ?—Yes, they did.

Trap or no trap, did you tell them that the little girl had got out of bed whilst you were away, had gone downstairs and gone to the scullery for water ?—Yes. She asked me and I said Yes.

And did Mrs. Tanner say to you : " Was not that enough to give the child its death of cold ? "—No, she did not ; she is not one of that sort. She is too false to say it to your face.

Did you say it was a bad sign ?—Yes, I did.

Mr. Justice Lush. What is a bad sign ?

Sir Edward Marshall Hall. The child having been sick the next day ?—I have heard a lot say they do that when they are taken for death.

Did Mrs. Tanner ask you if you had ever told Dr. Hadwen about this child going downstairs ?—No, she did not.

You said that neither to her nor to her husband ?

Mr. Justice Lush. Will you ask whether she told Dr. Hadwen on the 9th that the child had been down ?—Never.

Why did not you mention it then ?—I did not think of it then ; I was more troubled over the little girl.

Sir Edward Marshall Hall. Is that the real reason why you did not tell the doctor ?—It did not come in my mind while he was there.

Did you tell Mr. Tanner that you had not told the doctor because it was your own business ?—No, I did not.

If you had thought the sickness was a bad sign, and you knew that the child had been down in the scullery in her bare feet, why did you not tell the doctor ?—I do not know ; we do not think of everything just at the right time.

I must put to you some details of these visits which you are talking about. On the first visit to Nellie, that is to say, on the 1st August, did you tell the doctor : " The child has had a bad throat like the others " ?—No, he looked down the child's throat.

Did the doctor look at the child's throat ?—Yes, he did.

Did he say : " This looks rather like scarlatina " ?—No, he did not say anything about a scarlatina throat. He said she looked as if she had scarlet fever.

Then did he at once examine the child to see if there was any rash ?—Yes.

And he found no rash ?—No rash.

Had the child at that time a slight running at the nose ?—Yes.

Did you see him feel its pulse ?—No.

Do you know when a doctor feels a child's pulse ?—Yes.

Do not you know that the way to do it is not to let the child know you are feeling its pulse if you can possibly avoid it ?—I was in the room ; I saw all he did.

You swear that Dr. Hadwen did not take her temperature ?—He did not.

Did he take her temperature ?—No.

Did he examine her chest, back and front ?—The first day ?

I am talking of the first day ?—Yes, to see if she had a rash.

Then he told you to let her gargle her throat frequently with vinegar and water ; that is the same as he had done for Leonard ?—Yes.

Did he tell you to send to the surgery for some medicine, and you sent, and did you get it ?—Yes.

He came again on the 4th ?—Yes.

I suggest to you he found the child very much better ?—He did not.

That the throat was in a very much better condition ?—It was not.

And did you see him put his head down like that to the child's back, and listen ?—He did not near touch the child's back ; the child was laid down in bed.

Did he listen at the child's back ?—He did not.

Did he take the child's pulse ?—No.

That means you did not see him ?—I was in the room ; I was sitting on a chair at the side of the bed, and I should not have missed it.

Did he tell you he was pleased with the child's progress ?—No, he did not.

Did he tell you to keep up the gargle and the mixture ?—Yes. I told him that morning she could not do it so well as Leonard.

Did you say : " She has some difficulty in gargling," because she could not get the gargle back far enough ?—Yes.

Then did he tell you that you had better paint the throat with glycerine with a feather ?—That is on the 6th.

You say that that is all done in less than three minutes ?—Yes.

The next time he came was on the 6th ?

Mr. JUSTICE LUSH. That was on the 6th ?—About the throat.

Sir EDWARD MARSHALL HALL. Did you meet him at the bottom of the stairs ?—No ; I followed him up the stairs. He came in from the front, and I came in from the back.

Did you say—be careful—" Doctor, I think she is going on very nicely " ?—No, I did not. A neighbour stood at the back door, and I said, " I cannot stop, I want to show the doctor that in Nellie's nose."

I put it to you that on the 6th the child was ever so much better ?—She was not.

She had no temperature ?—She was laid down in bed, and the discharge was all over the side of her face that morning.

I suggest to you she was sitting up ?—She was not sitting up any morning nor any time anyone came into the house.

That the symptoms of the cold had cleared up, and so much so that he ordered a tonic for her ?—Yes, he ordered a tonic. He found her dozing that morning.

He ordered a tonic for her ?—I know he did.

He did not order a tonic for Leonard until he was nearly well ?—He ordered a tonic in a week's time.

And this is about a week's time ?—He did not find her sitting up in bed, nor did anyone see her sitting up in bed who came in the room. The discharge was all down the side of her face that morning. That was the morning I pointed out that part on her nose.

I suggest to you that you addressed Dr. Hadwen on that morning kindly, and were very pleased with him for having looked after her ?—I was not. He said as he went downstairs, just as though he was a bit excited, " She is getting on all right." He repeated the words twice. I never repeated the words to him nor said she was better.

On the Friday the child vomited ?—Yes.

Vomited more than once ?—Yes.

You never sent for the doctor ?—Not till the morning.

But never on the Friday ?—No.

Was it quite early in the morning the child vomited on the Friday ?—Yes, just after breakfast.

How many times did she vomit that morning ?—I could not say ; several times in the day.

Did you notice when she vomited that she was shivering ?—No.

Did you feel her hands at all ?—No, she was cold the beginning of the week.

On the morning she was vomiting, did you notice whether she had any perspiration on her forehead ?—No.

Or her hands ?—No.

How many times did she vomit in the morning ? Five or six ?—Not so often.

Three or four ?—About twice in the morning.

Mr. JUSTICE LUSH. Did not the doctor ask you, when he got there, how the child had been since he last saw her ?—No, he did not. I pointed out how ill the child was.

If you pointed that out, why on earth did not you mention these attacks of sickness ?—I did mention it.

Going downstairs ?—I did mention them ; I said, " She cannot keep the tonic down," and he said I was to dilute it with water. He did not point anything out to me about the child's illness.

Sir EDWARD MARSHALL HALL. I put it to you that until the doctor came on the Saturday morning you had never sent word to the doctor to say that the child was vomiting ?—No.

When the doctor came on the Saturday morning, did you tell him that the child had been vomiting all day Friday ?—Yes, I did tell him.

But that it had now stopped ?—Yes ; she had not brought anything up all through the evening and all night ?

Can you really give the Jury any explanation why, as a mother, fond of the child, with this new serious symptom, which you yourself say is a bad sign, you did not send for the doctor on the Friday ?—Because I thought he would call in. He had seen her on the Wednesday.

His time was half-past ten ?—I could not spare the children to be running after doctors. I had not one to spare. Leonard was not fit to go for him.

At half-past ten his time had passed and the child was vomiting, why did not you send then for him ? Which was the most important, that your child should be sent to the doctor's, or that your other child, who was ill, should get worse ?—I did not think it was so serious as that, or I should have sent for him.

Do you really suggest that Dr. Hadwen said that there was nothing the matter with the child ?—Yes, he did say it, and repeated the words twice : " There is scarcely anything the matter with her."

I put it to you that what he said was that the throat had cleared up nicely ?—It was clearing nicely ; " there is scarcely anything the matter ; she will soon be all right," and he repeated the words twice.

Did he examine the child then, very carefully ?—He felt her pulse, and he just examined her chest ; that is all he did that morning.

You have no doubt whatever that the child was very ill ?—Yes, she was ill, and I pointed out how ill she was.

When he said to you that the throat was clearing up nicely, did he say, " I think the child will pull through all right " ?—No, he did not. He said, " There is scarcely anything the matter " ; those are the words.

The child was always able to breathe through one lung ; she could breathe ; perhaps you do not know ?—No ; she could not talk for days, anyhow ; she did not want to talk at least.

Then you sent for Dr. Ellis, and Dr. Ellis came at once ?—Yes.

You did not see him do this operation ?—No.

Did you hear Dr. Ellis mention the word pleurisy ?—No, fluid.

Did you hear Dr. Ellis say anything about the condition of her lungs, or bronchitis ?—Yes, I did.

What did he say about bronchitis ?—She had bronchitis.

Acute bronchitis ?—I cannot remember " acute."

Dr. Ellis said bronchitis ?—Yes, and pneumonia. I was up in the room when he was tapping her with his fingers, not when he put the needle in.

Can you tell me about how long Dr. Ellis was there before he went away after he first came ?—I cannot say I can say exactly the time.

You say he was there about two hours altogether ?—Yes.

A long time ; you had never had a doctor there so long ?—He had to go home once.

How long was he away, ten minutes ?—I should think ten minutes to a quarter of an hour.

We know he came at half past 10, the poor girl died at 10 minutes to 1, and he was away 10 minutes, so he would be there about two hours. What was he doing all those two hours ?—He washed all his instruments before he went ; all he had used.

Did you leave word after the inquest that Dr. Ellis, if he came, was not to come to your house, but to your mother's ?—No, I did not leave word about Dr. Ellis ; I did not know he would come. I asked a neighbour if anyone came to say I would be at my mother's.

You know that Dr. Ellis did call at your house, and was sent on by the neighbours to your mother's ?—So the neighbours told me ; I did not know.

It was not Dr. Ellis only you did not want to call ?—I did not think of Dr. Ellis. I did not know he was calling. I did not know he would call. I only asked a neighbour, if anybody should come, to say I should be up home.

And Dr. Ellis had nothing to do with your desire to have an inquest ?—Nothing at all.

He wanted to give a certificate ?—Yes.

Which, of course, would have ended the matter ?—No.

Which would have ended the matter ?—Yes.

And you insisted on an inquest, and in that you acted entirely independently of Dr. Ellis ?—Yes.

Had you ever consulted Dr. Ellis before ?—No.

Had Mr. Fudge ?—Yes.

Was he Mr. Fudge's doctor ?—Yes.

Re-examined by Mr. VACHELL.

Was this the first time, this Saturday the 9th, you had seen Dr. Ellis to speak to ?—Yes.

Did he at that interview show any ill-feeling at all towards Dr. Hadwen ?—No, none whatever.

Did he say anything about Dr. Hadwen's treatment of the child ?—No.

And he examined her most thoroughly ?—Yes.

Did Dr. Ellis leave the house before the child died ?—Yes.

And when did you see him next ? — On the Monday.

What took place then. Was that when you told him that the child had died ?—No, my brother-in-law.

What did you go for ?—He called to tell me that he had proof that it was diphtheria.

How many times did you see him after that before the inquest ?—Only once.

Mr. JUSTICE LUSH. What was the date of the inquest ?

Sir EDWARD MARSHALL HALL. The 12th August at first. Then it was adjourned to another date.

Mr. VACHELL. About a month after.

Mr. JUSTICE LUSH. When did this witness give her evidence ?

Sir EDWARD MARSHALL HALL. On the 12th August.

Mr. VACHELL. On the first day. She was the first witness called.

Sir EDWARD MARSHALL HALL. There is one point I have omitted. (To the Witness.) At the inquest you never said a word about having found this piece of chewed tissue paper ?—No, I did not.

Mr. JUSTICE LUSH. Nor about the discharge from the throat.

Sir EDWARD MARSHALL HALL. No, nothing at all.

Mr. VACHELL. That is just what I was going to ask you. Were you the first witness called at the inquest ?—Yes, I believe so.

Before any doctors were called ?—Yes.

When did you first realise that there might be some importance about what you found in the bath ?—When I heard the doctors giving their evidence, I knowed what it was.

Up to that time, until the doctors had given their evidence, had you any idea that this that you found in the bath might have anything to do with your child's illness ?—Yes. I did know what it was when I saw it first.

When ?—When I saw it in the bath.

Mr. JUSTICE LUSH. What did you know ?—Because I had seen it in the child's throat.

What did you know when you saw it in the bath ?—I noticed what was in the child's throat.

Did you know it was important ?—I did not think it was important then.

Mr. VACHELL. When you gave your evidence, did you tell your story without any assistance from the Coroner, or were questions put to you by anybody ?—Without any assistance.

You told your story right away ?—Yes.

You made no mention then, apparently, about what you saw in the child's throat. How is that ?—I did not know it mattered all that. I did not think of everything.

Did you realise at that time what effect this that you saw in the throat had. Did you know of the importance of it ?—Not till I heard the doctors talk about it.

Besides yourself, what other people called and saw your child during her illness ?—Mrs. Peachey and two sisters.

What are their names ?—Mrs. Taylor, Mrs. Hotchkins, and Mr. Fudge.

Did they all see this child ?—Yes. When she was ill.

Did this discharge that you noticed from the nostrils, and, by the way, I think you said it was stained with blood ?—Yes.

Did that make its appearance before Dr. Hadwen saw the child on the 1st ?—Yes, right from the very first day she was took ill.

Was it to be seen on that day ?—Yes.

Did it ever cease or get better ?—No, it never ceased at all.

Was it to be seen, then, on each occasion when he called ?—Yes.

With regard to the offensive smell, what do you say about that ?—When did you first perceive it ?—From the very beginning as soon as she was took ill.

And was there any alteration in that during the illness ?—The smell got stronger.

At any time when Dr. Hadwen was there was the smell any better, or anything of that sort ?—No, it was no better ; it did not get any better at all.

Did you get any disinfectant at any time ?—Yes, only what a neighbour gave me. She gave me some on the Tuesday and that is what I was going to fetch the night the little girl came down.

You had gone for that on the 7th ?—Yes.

Mr. JUSTICE LUSH. When was the disinfectant brought ?—On the Tuesday.

Mr. VACHELL. Monday was the 4th. Had you asked the neighbour for this disinfectant ?—No, I told her what a smell it was.

So you went to fetch it, did you ?—Yes.

Apparently some weeks after the child died you had an interview with this lady, Mrs. Tanner ?—Yes.

And on that occasion you said something was a bad sign ; what was that ?—When the little girl walked downstairs I told her I thought it was a bad sign.

Mr. JUSTICE LUSH. I thought you said before that the vomiting, the sickness, was a bad sign ?—No, the coming downstairs was bad.

In what way ?—Because I have heard of so many getting out of bed and doing those sort of things two days before they have died.

You mean it was a bad thing to do. I thought you meant the vomiting was a bad sign after she had walked downstairs ?—No, I have heard of a lot of people like that.

You mean it is a bad thing to do ?—No, it is a bad sign.

Mr. VACHELL. Have you ever heard anything about it being bad for people to get up when they are ill and walk downstairs ?—Yes, I have heard most people say it was a sign of death.

A superstition ?—Yes.

Sir EDWARD MARSHALL HALL. May I put something about the dates ? Your Lordship asked me about the dates. The inquest was opened on the 12th August. This lady gave evidence, and Dr. Ellis gave evidence only. Then it was adjourned until the 14th August, when no evidence was taken, and it was formally adjourned until the 12th September, when this lady was again recalled and cross-examined on that occasion, and she said nothing about the patch and her evidence had been read over to her on the 12th, and nothing was said.

Mr. JUSTICE LUSH. I should like to know this ; I do not know whether you have asked it : When Nellie was taken ill, what did you understand had been the matter with Leonard ?—The doctor said it was an ulcerated throat.

And Dr. Hadwen's treatment of Leonard was successful ; the little boy got better ?—He got better, but he did not get well. I have had to take him to the doctor's since. He looked like a boy who had St. Vitus's dance.

But his throat got better ?—Yes, but the people did not know him, he got so changed.

You thought Nellie had the same illness that Leonard had ?—Yes.

Did the doctor treat the two children in the same way ?—Just exactly the same, the same medicine and all.

LEONARD BURNHAM, *sworn.*

Examined by MR. MICKLETHWAIT.

MR. JUSTICE LUSH. Was this witness examined before the Magistrates ?

MR. MICKLETHWAIT. No, my Lord.

MR. JUSTICE LUSH. You have given notice ?

MR. MICKLETHWAIT. Yes, we have. (To the Witness.) Are you 14 years old ?—Yes.

Do you remember when your little sister was ill ?—Yes.

During that week ?—Yes.

Did your mother go out one night ?—Yes.

Do you remember which day it was ?—I think it was Friday.

SIR EDWARD MARSHALL HALL. You can lead as to the date ; it was Thursday, the 7th.

MR. MICKLETHWAIT. Were you left in the house with Nellie ?—Yes.

Where were you when your mother was out, were you downstairs or upstairs ?—Upstairs.

Did Nellie come downstairs while you were in the house ?—Yes.

Tell us what you remember about it ?—She came downstairs and came in the kitchen where I was sitting by the fire and she went out to the back kitchen and got a cup.

MR. JUSTICE LUSH. What did she ask you for ?—Some water.

Was she in her nightdress ?—Yes.

MR. MICKLETHWAIT. Then what did she do ?—Walked out to the back kitchen.

Is the water out there ; is the sink there ?—There is a tap.

MR. JUSTICE LUSH. She did ?

MR. MICKLETHWAIT. She walked out to the tap ?—Yes.

Did she get some water ?—No, I had the cup and I turned on the tap and gave her some water.

Then did she drink it ?—Yes.

Then what happened ?—She went on upstairs and got into bed.

How long was it while she was down there ?—About two minutes.

Cross-examined by SIR EDWARD MARSHALL HALL.

Did you tell your mother when she came back ?—Yes.

SARAH JANE PEACHEY, *sworn.*

Examined by MR. MICKLETHWAIT.

Are you the wife of William Peachey and is he a butcher ?—Yes.

And do you live at 47, Vauxhall-road ?—Yes.

I think you are a neighbour of Mrs. Burnham's ?—Yes.

But no relation ?—No relation.

Did you know this little girl, Nellie ?—Yes.

Did you know her all her life ?—I knew her ever since she has been born.

What was her general health ?—I never remember her being ill but once, when she had measles and bronchitis.

How long ago was that ?—Four years ago.

Did you see her in her last illness ?—Yes.

Which day ?—On Monday, 4th August, was the first time I saw her.

What time did you see her ?—About ten o'clock in the morning.

Where was she ?—In bed.

Did you notice anything about her ?—There was a terrible smell, and a yellow discharge stained with blood.

From her ?—From her nose, and it was running right down her cheek.

That was at 10 o'clock in the morning when you saw her ?—Yes, in the morning.

Had you had any experience of diphtheria yourself before ?—Yes.

You had known a case ?—Yes.

And did you form an opinion as to what was the matter with her ?—Yes, I told her I thought it was diphtheria.

Did you say anything about what you thought to anybody ?—I told her I thought it was diphtheria.

I think you told us that you noticed the smell ?—Yes.

On this occasion ?—Yes.

Are those the things which you noticed or did you notice anything else about her ?—They were the two chief things I went by.

Did you see her again after that before she died ?—I saw her on Saturday, the 9th.

At what time ?—2 o'clock in the afternoon.

What was her condition then ?—She was very weak indeed. I asked her if she knew me, and I could just see by the motion of her mouth she did know me, but you could hear no sound.

Was she conscious ?—Yes, quite conscious.

MR. JUSTICE LUSH. That would be about four hours after Dr. Hadwen had seen her.

SIR EDWARD MARSHALL HALL. Yes, 4½ hours.

MR. MICKLETHWAIT. What was the condition, first of all, with regard to the smell ?—The smell was worse than it was on Monday and her nose was completely blocked.

You mean the discharge ?—The discharge was still running from it.

Where was she when you saw her ?—In bed.

You say you tried to speak to her ?—I spoke to her and said, " Do you know me ? " and I could see by the motion of her mouth she said " Mrs. Peachey," but you could hear no sound.

Cross-examined by SIR EDWARD MARSHALL HALL.

You thought she was very bad when you saw her on the 4th ?—Yes, I did.

And you had known her since she was born ?—Yes.

You thought she had got diphtheria ?—I did.

And you told her mother so ?—Yes.

Did you ask the mother whether the doctor thought it was diphtheria ?—No, I did not ask her.

Did you ask the mother ? Did the mother agree with you when you said it was diphtheria ?—She said she had never seen a case.

Did she agree ?—She said she did not ; she thought it was the same as Leonard and he had got better.

Did you tell her she ought to tell the doctor ?—No, I did not.

Did you go and see Nellie again between the 4th and the 9th ?—No.

To-day you have said she had a yellow discharge stained with blood running right down her cheek ?—Yes.

Have you had a talk over this since you gave your evidence before ?—No.

That is not the expression you used before ?—It may not be, but it is the truth. She had a very bad discharge from her nose and mouth which smelt very badly. It was green and red from the nostrils, but more watery from the mouth. I have seen a diphtheria case before.

You have not said that before till to-day ?—I may not have said it, but it was there.

It is curious that Mrs. Burnham's evidence was that she had a yellow discharge streaked with blood ?—It was there to be seen.

You described it one way to-day, but you mean the same thing ?—I mean the same thing.

You never said until to-day that the poor girl's nose was completely blocked ?—No, I may not, but it was completely blocked all the time.

You have given evidence twice before ?—Yes, I have.

Once before the Coroner and once before the Magistrates ?—Yes.

And on neither occasion did you say anything about the nose being blocked. You did ask Mrs. Burnham how she was getting on between the 4th and the 9th ?—I asked her every day and sometimes twice.

And you were satisfied or else you would have said so ?—I was never in the habit of going in unless I was asked.

Had you been asked to go on the 4th ?—I was.

On the 9th ?—I was.

If Mrs. Burnham had told you that the child was worse between the 4th and the 9th, would not you have offered to go and do something ?—Yes, if she had asked me.

Mr. JUSTICE LUSH. Did you ask how the child was ?—Every day and sometimes three times a day.

What answer did you get ?—That she was no better.

Re-examined by Mr. VACHELL.

Before the Coroner you put it this way: "The discharge seemed to be like blood and matter mixed" ?—Yes.

Is that correct ?—That is quite correct.

FLORENCE HOTCHKINS, *sworn.*

Examined by Mr. MICKLETHWAIT.

Are you the wife of Frederick Charles Hotchkins ?—Yes.

You reside with him at 22, Russell-street, Gloucester ?—Yes.

I think he is a storekeeper ?—Yes.

Was Nellie Burnham your niece ?—Yes.

Did you see her during her last illness ?—Yes.

On how many occasions ?—Three times.

Which was the first time ?—August 5th.

Where did you see her ?—In the bedroom.

What was her condition; what did you notice about her when you saw her ?—She was very hot and feverish but very ill, drowsy. She had a discharge from the nose.

What sort of discharge ?—I said a greenish colour when I gave my evidence, stained with blood.

Did you speak to her ?—Yes.

Did she answer you back ?—No.

How long were you with her on this first occasion ?—Half an hour.

And during that time did she not speak to you ?—No, not once.

Was there any smell there, did you notice ?—Yes.

What sort of smell ?—Nasty, disagreeable smell coming from the breath.

Then did you see her on another occasion. When was that ?—On August 8th.

What time of the day ?—I was there from half-past eight at night till half-past nine.

That night ?—Yes.

What was her condition then ?—She was very ill—much worse; very pale.

Was there any discharge ?—The same.

Was there any smell ?—Just the same.

You mentioned she was drowsy on the first occasion; what about the next occasion ?—The same; she was sleeping the whole of the time.

Mr. JUSTICE LUSH. Need you pursue this in quite so much detail. Of course, I appreciate the importance of proving the main symptoms, but it is enough, is not it, to get those one or two main facts from this and other witnesses ?

Mr. MICKLETHWAIT. Of course, drowsiness is important, I think.

Mr. JUSTICE LUSH. No doubt.

Mr. MICKLETHWAIT. What was the third occasion when you saw her ?—The night she died.

Just before her death was it ?—Yes, about a quarter past twelve.

Did anything happen before she died ?—Yes, she tried to speak and we could not understand anything she said.

Did she do anything besides that ?—Yes, she tried to vomit.

How long was that before she died ?—About a quarter of an hour.

Could you say whether she was conscious before she died ?—Yes, she was.

Right up to the time of her death ?—Yes.

Cross-examined by Sir EDWARD MARSHALL HALL.

Am I right in surmising that you are Mrs. Burnham's sister ?—Yes, I am.

Were you one of the family council who decided to send for Dr. Ellis ?—No.

Who were ?—My mother, my father, my brother, and Mr. Fudge.

Mr. Fudge ?—I do not know whether it was Mr. Fudge.

You were not one of the party ?—No, I was not home.

ALBERT AUSTIN FUDGE, *sworn.*

Examined by Mr. MICKLETHWAIT.

Do you live at 54, Barry-road, Saltley, Birmingham, and are you a foreman fitter ?—Yes.

And Nellie Burnham was your niece ?—Yes.

Did you see her during her last illness ?—I first saw her on the 7th August.

At what time ?—About 10 o'clock.

In the morning or evening ?—The morning.

What was her condition then ?—I thought she was very ill.

Was she in bed ?—Yes.

Did she recognise or talk to you when you saw her ?—She tried to speak but she could not. She tried to say something, but what it was I could not say; a kind of snuffle.

Did you notice anything about her appearance ?—She had this greenish discharge from her nose and tinted with blood.

You say that you noticed that ?—Yes.

Did you notice the smell ?—Yes, very bad indeed.

Did you see her again on another occasion, I think you said twice ?—On the Saturday.

That was the day before she died ?—Yes.

What time did you see her ?—Between nine and ten as near as I can say.

At night ?—Yes.

Was that when the decision was come to to call in Dr. Ellis ?—Yes.

It was after that ?—Yes.

And as the result of a discussion you had with other people, did you telephone to Dr. Hadwen ?—Yes.

At what time ?—This would be about—I cannot say to the minute—half-past nine I should think, something like that.

Will you tell us what you said to him ?—I rung on the 'phone and I asked if that was Dr. Hadwen. He said "Yes," and I told him I was speaking on behalf of Mrs. Burnham for Nellie Burnham and I was not at all satisfied with his treatment and that we had decided to call in another doctor. He said, "Oh, oh. I have done my best," and I said to him, "You understand we are going to call in another doctor." He said, "Yes, oh," and then rang off.

Cross-examined by Sir EDWARD MARSHALL HALL.

Are you a brother of Mrs. Burnham's ?—Brother-in-law.

Did you marry her sister ?—Yes.

I suppose you were on your holidays ?—Yes.

And you saw Nellie twice ?—Twice.

Did you know she had been ill all the week ? When did your holidays begin ?—On the Monday.

Do you remember Mrs. Burnham telling you, when you went to see her the first time, that the child had been sick ?—No.

Do you know whether she had been sick ?—No.

What day of the week was it you went to see her the first time ?—The 7th would be the Thursday.

You worked it back in your mind. I noticed you said you went on the 7th and then on the Sunday; you did not say the 9th. I am suggesting to you it was the 8th you went ?—No, the Thursday.

You went two days running; you are sure it was the 7th ?—The Thursday and the Saturday.

You attended the family council ?—Yes.

Who was there; you and Mrs. Burnham ?—Yes.

And Mrs. Burnham's father and mother ?—No.

She told us so just now. Who was at the family council ?—Myself, Mrs. Hotchkins, Mrs. Taylor, and Mr. Taylor; there were several members.

I suggest what he did say was, "I have done my best, I am very sorry, it is a free country, you can call in who you like"?—No, nothing like that.

You say he said what you have told us?—Yes.

Of course, you were a little bit angry?—I was not angry.

Mr. JUSTICE LUSH. Had you come to any conclusion as to what the child was suffering from?—No.

MATILDA TAYLOR, *sworn.*

Examined by Mr. MICKLETHWAIT.

Are you the wife of Ernest Taylor, an electrical fitter of 32, Ladysmith-road, Gloucester?—Yes.

Was Nellie your niece?—Yes.

Did you see her during her last illness?—On August 9th.

The day before she died?—Yes.

What time did you see her?—About half-past nine.

In the morning or evening?—In the morning.

What was her condition then?—She was very ill.

Did you notice anything about her?—Yes, she had a discharge from the nose greenish and blood, and a very offensive smell in her breath.

Were you present when Dr. Hadwen called?—Yes.

Were those symptoms you have told us of apparent at the time he called?—Yes.

What was her condition so far as drowsiness was concerned?—She was sleeping.

Was she sleeping in her bed when you saw her?—Yes.

Did you see what Dr. Hadwen did?—Yes.

What did he do when he called?—He sounded the chest and felt her pulse and looked down her throat.

Mr. JUSTICE LUSH. How did he look down her throat?—Put his two fingers in her mouth.

Mr. MICKLETHWAIT. Did he say anything about her condition?—He said there was scarcely anything the matter with her, she would soon be all right.

Did he say anything about the condition of her throat?—He said the throat was clearing nicely.

Did you hear him say anything about what the mother should give her?—Cold milk.

What did the mother say to that?—She could scarcely take it, swallow the milk.

Did she say anything about her not being able to take her medicine?—Yes, she said the child could not keep the medicine down.

What did the doctor say to that?—She was to give it with a little water.

How long did the visit last?—I left about eleven.

Dr. Hadwen's visit?—About five minutes.

Were you present when she died?—Yes.

Did anything happen just before?—She tried to vomit a quarter of an hour before she died. I could see something in the child's mouth, I raised her head and a little slipped from her mouth.

Mr. JUSTICE LUSH. I do not quite know what you mean?—There was something in the child's mouth and I raised her head, thinking she would be able to bring it up.

Mr. MICKLETHWAIT. Did you see what it was?—It was a small piece of like slimy, yellowish skin streaked with blood.

That came from her mouth?—Yes.

Was that before she died?—A quarter of an hour.

Cross-examined by Sir EDWARD MARSHALL HALL.

Are you a sister of Mrs. Burnham's?—Yes.

Have you told the truth?—Yes.

Let me read to you what you have said: "I saw she was trying to vomit; I could see something in the child's mouth, and something slipped from her mouth, a small piece like a slimy, yellowish skin, streaked with blood." Have you ever said that before to anybody?—Yes.

Who to?—To the last sitting.

I have your evidence before the Coroner, and before the Magistrates, and I suggest to you you never said anything of the kind?—I did.

I will read you what you said on both occasions, first of all taking the Coroner's Inquest: "I was with the child after Dr. Ellis left, and when she died she tried to vomit, about a quarter of an hour before she died, but she did not bring anything up." Before the Magistrates you said this: "I was present when Nellie died, and a quarter of an hour before she died she tried to vomit, and a little came from her mouth when I lifted her head"?—I did say it.

Do you mean to say "a little came from her mouth" is the same as what you have said to-day?—Yes.

"A little came from her mouth" means a little liquid came from her mouth, does not it. Were you cross-examined before the Magistrates by Mr. Clements and were you asked why you had said nothing about it before, and did you say this: "I did not say anything before the Coroner as to anything coming from the mouth; I have only paid attention to it since the various doctors' evidence." Do you mean to tell these Jurymen that you saw "a small piece like slimy, yellowish skin streaked with blood slip from her mouth"?—Yes.

Do you mean to tell the Jury that is true?—Yes.

Then why did not you tell the Coroner?—How did I know what it was?

Why did not you tell the Magistrates?—I did.

You did not; you told them something came from her mouth, a little?—I did not know what it was.

Do you mean to say when you said, "A little came from her mouth," you meant a piece of slimy stuff of this sort, streaked with blood?—I was not asked that question.

You were not asked to-day. You are a sister of Mrs. Burnham's?—I am.

And you, after the doctors' evidence, like her, appreciated the importance of whether anything had come solid from her mouth, did not you?—Certainly.

Have you given the exact words you have given in evidence here to-day to anyone representing the Public Prosecutor; have you told those exact words to anybody?—I do not remember.

Have you made a statement?—I have.

Did that statement include those words?—It did.

Mr. JUSTICE LUSH. Why do you say that?—At the Court, the last time we were there.

That is not quite what you are asked now. You have given a statement as to what you are going to say in this Court, have not you, to the solicitors?—No, I have not.

Sir EDWARD MARSHALL HALL. You gave a statement to the Public Prosecutor before the Magistrates' proceedings?—Before the inquest.

Did you give a statement before the inquest?—I did.

Sir EDWARD MARSHALL HALL. The Public Prosecutor did not come into the matter till after the verdict of the Coroner's Jury.

Mr. VACHELL. We have what the Treasury always supply, the Coroner's Depositions, and the Magistrates' Depositions; there is no separate proof.

Sir EDWARD MARSHALL HALL. (To the Witness.) I want you to realise the importance of this: "Something slipped from her mouth, a small piece, like a slimy, yellowish skin, streaked with blood." Did you tell the gentlemen who took your evidence down those exact words?—No, I did not.

Therefore you never said it before the Magistrates, or before the Coroner, and you did not tell the Solicitors to whom you gave your statement, and you have said it now. Do you say he put two fingers down the child's throat?—Yes, I believe he did.

You have sworn it to-day; you told my Lord he put two fingers down?—Yes.

Do you swear that is true?—Yes.

Do you mean to say you really tell the Jury the doctor put two fingers down the throat in order to see?—Yes, he has put them down my children's throat, so I know what he does.

Before the Magistrates you said one finger?—No, I did not.

I have got it here : " He put his finger in Nellie's mouth " ; that is before the Coroner. You did say two fingers ?—Yes, I did say two fingers.

Was it one, or two fingers ?—It was two fingers.

And that is true ?—Yes.

Would not the effect of putting two fingers down the throat be to absolutely obscure the throat ; you could not see it at all——. I will let the Jury see your gesture ; that is quite enough for me.

DR. EDGAR SEVERN ELLIS, *sworn.*

Examined by Mr. Vachell.

Are you a Member of the Royal College of Surgeons, and a Licentiate of the Royal College of Physicians, England ?—Yes.

Practising in Gloucester ?—Yes.

How long have you practised here ?—Since 1906.

Were you at some time on the night of Saturday, the 9th of August last, called by telephone ?—No, personally.

You were called upon to attend this little child, Nellie Burnham ?—Yes, personally, not by telephone.

What time did you arrive at the house where she was ?—I cannot say, but I should say about half-past ten.

What did you find there ?—I found the little child seriously ill ; she had got a temperature of 102·5, and a pulse of 154.

What is the normal , everyone knows the temperature, that is 98·4, is not it ?—Yes.

And she was—— ?—102·5.

What is the normal pulse of a child of her age, about ?—They vary a lot ; an adult's pulse would be about 70 to 80, but children are higher.

Her pulse was ?—154.

Mr. Justice Lush. That is exceptionally high ? —Yes, febrile.

Mr. Vachell. Was she in bed ?—Yes.

What was her condition ?—Toxæmic.

You must put it into English for us all ; that is something to do with poison ?—It means it was by an absorption of poisons in the blood ; like people in the later stage of fever.

Was she at all approaching death ?—Yes.

Mr. Justice Lush. How long was this before her death ?—She died at 12.40, I believe.

Mr. Vachell. That is to say, on the Sunday morning, within two or three hours after you were first called in ?—Yes.

Tell us what you did, and what symptoms you observed ; perhaps the symptoms first ?—As I came into the room—I had been told it was probably a case of pneumonia—I noticed her very rapid breathing, and I at once thought of pneumonia, and I went over the lungs. I found the right lung solid, and the left lung bronchitic. I looked at the throat, and it was full of membrane, membrane right across from tonsil to tonsil.

In the throat ?—Yes, and there was a discharge from one nostril, I forget which. I took a swab.

What was the nature of the discharge ?—A greeny, dirty discharge, just tinged with blood. I took a swab from the throat, not from the nose, and then I wondered whether, possibly, there might not be fluid in the lung, because it is very difficult indeed to distinguish between solid lung and fluid ; I thought it would be wise to make an exploration, so I went home and fetched some instruments, and I did an exploration. I found no fluid.

Is that something in the nature of a syringe ?—Yes.

With a sharp point ?—Yes.

You punctured the side ?—Yes, I have got it here, if you wish it in evidence.

How did you examine the throat ?—I had been warned it was a throat case, and I had brought an electric tongue depressor with a lamp at the end which I put inside.

Mr. Justice Lush. Is that the usual way ?—No, it is too big for a doctor to carry it with him, but he would take it with him if he were going to a serious case. In the ordinary way I use a pocket torch like *that* (*indicating*).

Mr. Vachell. Or do you want anything much better than a spoon for a depressor ?—In the ordinary way, if I am out, and I am asked to look at a throat, I borrow a spoon, and shine my torch in. If I have a special case, or a difficult child, and I am warned about it, I bring my special apparatus with me.

Did you notice anything offensive in the way of smell ?—Yes.

What was that ?—All throats smell, but I cannot distinguish one from the other.

There was some smell ?—Yes, undoubtedly.

What, in your opinion, was the child suffering from ?—Diphtheria and pneumonia.

Mr. Justice Lush. Had you any doubt that it was diphtheria ?—None whatever.

What was it that proved it to you, because you had not had the swab examined, of course ?—I was so certain that I notified it before I had any result from the swab.

What was it that made you clear it was diphtheria ? —It was such obvious diphtheritic membrane.

Mr. Vachell. Is diphtheria accompanied sometimes by an enlargement of these glands ; I think you call them maxillary ?—No, cervical glands.

That is one of the symptoms, or one of the accompaniments ?—Yes.

Did you discover any enlargement ?—Yes, but it was not very marked.

How long were you there altogether ?—I cannot tell. I got there about half-past ten, then I had to examine the lungs and the throat, then I had to go home and fetch my apparatus, and go back again. I should think about an hour and a half each time, and about an hour getting my apparatus.

Having formed your opinion as to what the child was suffering from, did you administer antitoxin ?—No.

Why ?—Too late ; the child was dying.

You took a swab. When did you send the notification to the proper officer ?—Early the next morning, I think.

There is some Act, is there not, under which certain diseases are what you call notifiable diseases ?—Yes.

You are bound to give notice ?—Yes.

You gave notice the next morning, and when did you send the swab ?—The next morning too, I think.

Did you send them both to the same officer ?—No, the notification goes to the Guildhall, and the swab goes to Dr. Washbourn.

Is he appointed by the authority to examine, bacteriological examiner ?—Yes.

Mr. Justice Lush. Did I understand you to say that you notified it as a case of diphtheria on the morning of the 10th, and you received the swab on the morning of the 11th ?—I do not know when I received the notification.

I thought you notified it ?

Mr. Vachell. Of course he took the swab in the lifetime of the child, and the next day, the Sunday, the 10th, the child died early. He did two things. He notified the authorities at the Guildhall, and he sent the swab to Dr. Washbourn.

Mr. Justice Lush. I thought he had got back the result ?—I did not wait for the result.

Mr. Vachell. You do not know quite how long it was before you got the report back ?—I do not know.

I do not know if your sense of smell is affected at all, or whether it is normal ?—I think it is fairly good, but it is not good enough to spot diphtheria ; I admit I cannot. It is only some who can, with special practice.

Did you take some other swabs in that family later ?—No.

None at all ?—Not in the family ; there was a child who had been visiting there.

Is that a little girl called Olive Cornock ?—Yes.

Sir Edward Marshall Hall. I cannot see how this is evidence.

Mr. Justice Lush. It is a little remote, is not it ?

Mr. Vachell. It is only this, if it is going to be said that this little girl, Nellie, never had diphtheria at all, then I think the fact that her playmates, and the little children of her own family all suffered at the same time from this diphtheria would be evidence, but, of course, I am in your Lordship's hands; that is the reason.

Mr. Justice Lush. It strikes me as a little weak compared with the strong affirmative evidence which you have presented.

Mr. Vachell. Yes, my Lord. Of course, I do not know yet how far my learned friend is going.

Mr. Justice Lush. I do not think myself it carries the case appreciably further.

Mr. Vachell. If your Lordship pleases; then I say nothing more about that.

Mr. Justice Lush. We shall have to pursue that if you begin it because we must know if it is true that Olive Cornock suffered the disease as well.

Mr. Vachell. That is simply dealt with because I am calling the medical officer from the Isolation Hospital.

Mr. Justice Lush. If you press it, and you are going to deal with it we must take it.

Sir Edward Marshall Hall. From the notice my friend has given us he does not prove the identity of the swabs.

Mr. Justice Lush. If Sir Edward is going to challenge the accuracy of the diagnosis about diphtheria—I do not know if you are.

Sir Edward Marshall Hall. From my view of the case it is not really important. I must say this, that I am not going to admit on behalf of Dr. Hadwen that the child was suffering from diphtheria because Dr. Hadwen says in his opinion the child was not suffering from diphtheria, and he will say so.

Mr. Justice Lush. If you are going to make it an issue at all, that the child had diphtheria and died from it, I do not think I can shut the evidence out, although I think we have got enough.

Mr. Vachell. I shall take that intimation from your Lordship, and if there is enough I am content.

Mr. Justice Lush. You see Dr. Ellis notified it before he had ever got the result.

Sir Edward Marshall Hall. I am not going to question Dr. Ellis's diagnosis that he thought this was diphtheria. He cannot do more than say it was diphtheria in his opinion, but I am not going to admit in this court, or any other, that the finding of a Klebs-Loeffler bacillus is absolutely indicative of diphtheria. If I am bound to challenge that I shall go on challenging it. That is one point I am trying to avoid in this case.

Cross-examined by Sir Edward Marshall Hall.

You diagnosed a solidified right lung, did you not ?—I did.

The left lung apparently reasonably clear ?—No, acute bronchitis.

Dr. Washbourn, as a matter of fact, did not agree with you upon that diagnosis; he said there was some congestion ?—Yes.

Have you any doubt whatever that that child actually died of pneumonia ?—Yes, the child died of diphtheria and pneumonia.

How did the diphtheria kill her ?—The diphtheria spreading down into the lung. It was really all one disease.

Do you mean to say that the solidification of the lung was the direct consequence of diphtheria ?—I cannot swear to that; that is only my opinion.

Mr. Justice Lush. What do you say yes to then ?—It is my opinion that it was one disease, that the diphtheria had spread down into the lung and caused pneumonia, but I cannot say for certain that it was pneumonia caused by diphtheria.

You know it was pneumonia ?—Yes.

Sir Edward Marshall Hall. The pneumonia in this case was called unilateral, was it not ?—Yes.

Dr. Washbourn is a gentleman we can all rely upon ?—Yes.

The pneumonia was unilateral ?—Quite so.

Have you ever known a case of pneumonia, a sequela of diphtheria, in which the pneumonia has been unilateral ?—No, or bilateral.

Mr. Justice Lush. Must it not be one or the other ?—I have not come across a case before.

What am I to understand by that ?—These cases go to hospital; we do not get them in general practice.

Sir Edward Marshall Hall. Do you study current medical literature ?—Yes.

Mr. Justice Lush. Is this what I am to understand, that you do not know of a case where the pneumonia is a sequela of the diphtheria, and you do not know whether it may be unilateral or bilateral ?—No, it is a question for pathologists.

Sir Edward Marshall Hall. Will you give me the same answer when I ask this: Have you ever heard of lobular pneumonia and lobar pneumonia ?—Yes.

You know the distinction between the two ?—Yes.

Is one of those unilateral and one bilateral ?—No.

Which was this ?—This was unilateral.

Which was this, lobar or lobular ?—I cannot tell. When I auscultated that chest it was so late; the whole lung was solid.

Do you know Dr. Washbourn said at first it was lobar, and it was not until he was recalled some months after that he said he might have been mistaken; it might have been lobular ?—I understood that, and in my own consulting room I did not know how he had made the distinction.

Do you know that hepatisation is peculiar to one of those two forms ?—No, peculiar to either.

Do you suggest you can ever get the hepatisation in lobular pneumonia ?—They go solid if the thing is sufficiently advanced.

You gentlemen use wonderful words and expressions, but you do attach some meaning to them, do not you ?—I hope so.

Mr. Justice Lush. I am afraid I do not know enough about them. One is lobular; what is the other ?—Lobar.

Do you say you could not tell which this was ?—I was not asked. I was not at the post mortem.

But if you had been and found the lung was solid ?—I am not satisfied as to which it was.

Sir Edward Marshall Hall. You are even now not satisfied ?—No.

Do you really mean to pose before this Court as a gentleman who does not know; that you have no experience; you cannot say what the common sequela of diphtheritic pneumonia is ?—I know perfectly well.

But you have never had a case where there has been a post mortem after diphtheria and pneumonia and pneumonia supervened, have you ?—Never.

Then it is not very common for it to intervene ?—It happens in hospital possibly.

Let us try another subject. Do you know that a sudden chill will in the case of an enfeebled vitality produce pneumonia ?—Yes.

Do you know that if pneumonia is produced in that way that the pneumonia, which is the sequela, is lobular and not lobar ?—I do not. I know it usually is.

Mr. Justice Lush. Let us have that again.

Sir Edward Marshall Hall. I put that question the wrong way round on purpose, and he accepted it. Now I will put it the right way round. Is not it a fact that the pneumonia which is the sequela of a chill is always lobar pneumonia and not lobular ?—Yes, I thought you said that, as a rule.

Mr. Justice Lush. As a rule, pneumonia caused by chill is lobar ?

Sir Edward Marshall Hall. Is one of the first symptoms of a pneumonia onset as the result of chill, vomiting. Is that one of the first symptoms you get ?—No, not necessarily at all.

But is it sometimes ?—Yes.

Does pneumonia of that kind strike you down in a second ?—No.

Not if it supervenes on a weakened vitality ?—If it is sufficiently weakened, yes.

If a child is feverish, and one of the lay witnesses has told us the child was very hot and feverish all the time, and that child goes downstairs in her bare feet and nightgown, out of a hot bed where she has been kept for days, and goes into a scullery and gets a drink of cold water, and gets back to bed, do not you think that is most likely to produce a serious chill ?—It may, certainly.

If it produces chill in the condition which we know that child to have been in, a diphtheritic condition, would not pneumonia very probably supervene ?—It might.

And if pneumonia did supervene that pneumonia would in all probability be lobar ?—Yes.

Mr. Justice Lush. And would it be followed by vomiting ?

Sir Edward Marshall Hall. And one of the first symptoms might be—he only goes as far as that—vomiting. If Dr. Washbourn is right when he says this was lobar pneumonia—assuming he has said it, and assuming he is right—do you then think it is more probable that that pneumonia was a sequela of diphtheria, or the consequence of the chill contracted on the 7th ?—As a sequela.

You think it was even then more probable even as lobar pneumonia ?—Yes.

Although you frankly admit you have never known of a case of lobar following diphtheria ?—Or lobular ; I have never known of either.

Mr. Justice Lush. I do not follow that quite. If it was quite reasonable of the child going down with her bare feet into the kitchen to get water, and if it was a reasonable consequence she should get pneumonia, and if it was lobar pneumonia she got which was in fact followed by vomiting, would not you think it more probable that it was the consequence of the chill than that it was the sequela of diphtheria ? Is not that the question ?

Sir Edward Marshall Hall. Yes, exactly.—I do not think so, for two reasons. First of all there was sufficient diphtheritic membrane in the throat and nasal discharge to explain why her lung should have been affected. It is not uncommon for lobar pneumonia to follow diphtheria, but it is not the usual thing, and it is rather an extraordinary coincidence, to say the least, that the membrane was found in the right lung, and it was the right lung which was pneumonic.

Mr. Justice Lush. The membrane was found in the right lung ?—The bronchus. The membrane was found going down to the right lung, and it was the right lung which was affected. Another thing was the question of dates, and the period of incubation of lobar pneumonia following a chill such as Counsel suggests is at least, I should say, 24 hours.

Sir Edward Marshall Hall. I did not suggest 24 hours.—No, I am suggesting that ; at least 24 hours. Then there is evidence that the lung had been hepatised for a certain time. The lung had been congested for so many days.

Do not let us confuse the Judge. Dr. Washbourn has said the pneumonia was two or three days' existent when he examined it ?—Yes. Allowing 24 hours for incubation the dates just fit. It is rather a tight fit, but they do fit.

So they do for the date of the chill. I was going to make an important point of that ?—I am admitting your point.

Mr. Justice Lush. They fit the chill exactly. She went down ; on the 7th she vomited, and showed the symptoms on the 8th, that is the 24 hours you mentioned, and two days afterwards the pneumonia is so developed that it is solid ?—Precisely ; it is a tight fit, but it fits ; that is my point.

Sir Edward Marshall Hall. Will you disabuse your mind for a moment of the fact that Dr. Hadwen was the doctor in this case ?—Certainly.

You were told on this Saturday night that the people were dissatisfied with their existing medical man ?—Yes.

That, by the etiquette of the profession, frees you from responsibility ; it entitles you to see the patient without consulting the doctor ?—No.

Mr. Justice Lush. What do you say No to ?

Sir Edward Marshall Hall. The etiquette of the profession does not free him from the necessity of informing the other doctor he has been called in. I suggested it did when they said they were dissatisfied, but he tells me it does not. If it had been any other doctor but Dr. Hadwen would you not have at once communicated with the doctor ?—No.

Why not ?—There was no point in doing so. They said they did not want Dr. Hadwen again.

That is what I have put to you. If they said to you they did not want Dr. Hadwen, that relieved you of the necessity of communicating with Dr. Hadwen ?—No, not until he had been communicated with himself.

But not by you ; as long as they communicated ?—Quite so.

Unless they had said that they did not want the doctor who had attended them again the etiquette compels you, does it not, to inform the doctor that you are going to see the case ?—One simply does not know until they have informed the doctor.

Either they or you ?—Yes.

You went and saw this case ?—Yes.

Were you told that Dr. Hadwen had diagnosed it as an ulcerated throat ?—I think I was, but I will not be certain.

Who told you it was probably a case of diphtheria ?—Mr. Fudge, when he came.

Mr. Justice Lush. Who told you it had been diagnosed as an ulcerated throat ?—I am not sure whether anybody did ; I cannot remember ; it is three months ago.

I thought you said somebody did ?—I think somebody did, but I am not certain.

When did you hear anybody suggest that diphtheria had been suggested as the illness ?—Certainly somebody did. Mr. Fudge, and a friend of his, I think, came with him : one or the other suggested it.

Sir Edward Marshall Hall. Did they tell you any words to this effect, that Dr. Hadwen had muddled up the case—I do not give you exact words, but was that the effect of what they told you ?—That was the suggestion.

The child died. You were informed of it early on the Sunday morning ?—Yes, of the death.

How far from you does Dr. Hadwen live ?—About a third of a mile.

Are you on the telephone ?—Yes.

Is he on the telephone ?—Yes.

Did you think it courteous to telephone him to tell him that a patient of his, whom you had been called in to see, had died ?—I did not.

Did you think it courteous ?

Mr. Justice Lush. Do you mean you did not think it courteous not to tell him, or you did not think you did tell him ?—I mean I did not do it.

We all know that, but did you think it courteous not to do it ?—I did not see any reason why I should.

Sir Edward Marshall Hall. I will try and show you a reason why you did not.

Mr. Justice Lush. " I did not telephone ; I saw no reason for doing it."

Sir Edward Marshall Hall. Did you offer to give a death certificate ?—I could not give a death certificate.

Do answer that question. Did you offer Mrs. Burnham to give her a death certificate ?—No, certainly not.

Did she say she would not have a death certificate, and refuse it ?—Yes.

Although you told her you could not give her one ? I want to be precise over that.—What I did say was that I could inform the Coroner, and it was possible an inquest might be avoided, and she objected to that, and she said she wanted an inquest at all costs, to be exact.

That is your reason, is it ? Will you kindly look at what you said before the Magistrates : " I would not give a death certificate because I had not attended Nellie Burnham for a time prior to her death." That is precisely what I say now.

Do you mean to tell me that you, having been called in two hours before this child died, and being satisfied that the child died of diphtheria and pneumonia, were not entitled to give a certificate ?—No.

You do not say that you know you might have given a certificate ?—The certificate of death states : " I have attended so and so in the last illness." I had not ; I was called in when the child was dying.

Is not that her last illness ?—No.

Do you mean to say you could not have given a certificate of death ?—I do not think so.

Be careful. — Only with the permission of the Coroner.

Did you tell the Coroner that you were quite willing to give a certificate of death ?—I told the Coroner that I was quite willing to tell him what the child died of.

That was not my question. Did you tell the Coroner this ? Did you say you were prepared to give a death certificate if the Deputy Coroner approved ?—I was prepared to certify actually what the cause of death was, but I was not prepared to sign the official certificate.

Do not quibble with me ; certifying what causes the death is not the colloquial word for death certificate. Would this statement be true, that you were prepared to give a death certificate if the Deputy Coroner approved ?—It depended entirely on what you mean by death certificate, but not the official form.

Have you ever heard of death certificate meaning anything but the official death certificate ?

Mr. JUSTICE LUSH. Is that in re-examination ?

Sir EDWARD MARSHALL HALL. No, my Lord. There have been proceedings in the High Court, and it is an Exhibit to an Affidavit which was put forward by my learned friends. (To the Witness.) I am sorry to put it to you, but you have a very strong feeling against Dr. Hadwen, have you not ?—No, I have not.

Be careful.—I am very careful.

I have more to ask you than I want to ask you. I am not going through all the correspondence in the Press, because I will not bother about it, but during last August did you write to the Editors of two London papers asking them to interview you in reference to Dr. Hadwen ? Be careful of your answer. Did you write to the *Daily Express* and the *Daily Mail* asking them to send representatives to interview you, as you could give important information with regard to Dr. Hadwen's medical position ?—You are referring to August, last year ?

Yes. You did ?—Yes.

Did they both send representatives ?—I forget now. I think one of them did.

Both. Shall I bring them both into Court ; they are here ?—No, I do not dispute it.

Was your communication to them so libellous that they never printed a word of it ?—I forget entirely.

Did either the *Daily Mail* or the *Daily Express*, or the Gloucester paper, print any of it ?—I do not know they did not.

Did you tell these people that Dr. Hadwen was not entitled to the medical qualifications he held ?—Nothing of the sort.

Did you tell them that he was not entitled to the qualifications that appear after his name in the books of reference ?—I told them there was a discrepancy.

Did you tell them this, first of all, if I may generalise it. Were not the contents of your communications to both these newspaper men a violent attack upon Dr. Hadwen ?—No.

And an attack upon Dr. Hadwen's professional status ?—No.

Did you suggest that he had no right to use some of the degrees and diplomas credited to him in a book about Gloucester men printed locally ?—I pointed out the discrepancy between that locally printed book and the Medical Register.

Did you say that Dr. Hadwen had only been a chemist's assistant ?—No, I did not.

Before he became a doctor ?—I have always heard he has been a chemist, and I may have said so, but I never said chemist's assistant.

And in the letters you wrote to the *Express*, and to the other paper, did you say : " I have some very interesting information to give your representative concerning Dr. Hadwen, if he will kindly call " ?—I wrote to one of them, because he specially asked me for information.

Do you know the names of the two gentlemen ?—I do not.

They are Mr. Webber, and Mr. Pampheno ?—That was one, I think.

I put it to you that you went out of your way to try and damn Dr. Hadwen's professional reputation last August ?

Mr. JUSTICE LUSH. Was that the month in which the child died ?

Sir EDWARD MARSHALL HALL. No, August, 1923, the year before.

Mr. JUSTICE LUSH. I did not gather that.

Sir EDWARD MARSHALL HALL. I did put it to him. In August, 1923, there had been a very acrimonious correspondence between you and Dr. Hadwen, had there not ?—Yes.

I see two of them are exhibited ; they were put in by the prosecution before the Magistrates. You put in a very insolent letter ?—It was the letter of an angry man, I admit.

Therefore I am not alluding to those, but after the anger had subsided, and the contest about vaccination had subsided, did you deliberately go out of your way to get into communication with London papers ?—They asked for information, and I gave it.

Mr. JUSTICE LUSH. I did not gather that. I thought you volunteered the information to the London papers, from what you said ?—They asked me to send anything I could.

Was that before, or after, you communicated with them ?—They asked me before.

Sir EDWARD MARSHALL HALL. Do you put that upon me ?—Certainly.

Mr. JUSTICE LUSH. I gathered from your answer before that you wrote first ?—No, they called on me long before that, and asked for information, and when they left they said : " Will you tell us anything more you hear ? "

Sir EDWARD MARSHALL HALL. I do want you to be careful. Did you write a letter marked " private and confidential " to the Editor of a London paper saying : " I have some interesting information to give your representative, if he will kindly call upon me *re* Dr. Hadwen " ?

Mr. JUSTICE LUSH. Was that letter Sir Edward is quoting the first communication that passed between you and the Editor of the paper ?—No. The reporter called on me, and asked me to give all the information I could.

Before you ever wrote to him ?—Yes.

Sir EDWARD MARSHALL HALL. The reporter called upon you ? — The representative of the paper.

Then you wrote to the Editor of the London paper ?—I did not know where the reporter was.

Why should you, a member of the same profession, take upon yourself to communicate to a London paper matter derogatory to one of your brother professionals in the City ?—Because he had been communicating to the local Press, and to the Press all over the world, matter derogatory to me, and to everybody else in the profession.

In saying he did not believe in vaccination ?—He said more than that.

He simply said he did not believe in vaccination, and you people did, and you took it upon yourself to say that that was a reflection personally ?—It was not a question of belief in vaccination ; it was a question of the epidemic here, and the suggestion he made was that there was no small-pox in the town ; it was all chicken-pox, and that the whole epidemic had been trumped up for the benefit of the members of the profession.

So you thought you would communicate private information with regard to his professional status to the newspapers ?—I had been asked to give all the information I could.

Mr. Justice Lush. Only chicken-pox, he said?—Yes.

Sir Edward Marshall Hall. Do you know he was never given an opportunity of attending the post mortem on this dead child?—Yes. No more was I.

What have you to do with it; you are not charged with the manslaughter of the child?—No.

It may be, may it not, that the exploratory operation of yours, by the piercing of the lung to see if there was any fluid, having regard to the condition of that child, accelerated that child's death by some minutes, or possibly hours? I put it to you that that was a totally unnecessary and unjustifiable operation?—It was absolutely the correct thing to do.

Having made up your mind to the fact that one lung was solidified ——.—I had not made up my mind it was solid; that is why I put the needle in.

Supposing you had found fluid, what would have been the effect?—The question then would have been to see whether it was worth while draining the lung, so as to relieve the respiration.

I suggest to you that the only possible justification for that exploratory operation would have been if you had diagnosed pleurisy or effusion?—Quite, if I had.

But you had not diagnosed pleurisy or effusion; you had diagnosed solidity?—I had not diagnosed anything; I did not know.

You told us in your evidence: "I found the right lung solid."—That was the ultimate conclusion I came to.

It was your first diagnosis?—I put in the needle to make dead certain there was not any fluid. It is rather splitting hairs, is it not?

If you had had a reasonable doubt as to whether there was not effusion, and pleuritic effusion, then you would have been justified in exploring, would you not?—I thought there was effusion; that is why I did it.

May I take it that you were in doubt as to whether your diagnosis of solidity was correct?—I wanted confirmation.

Mr. Justice Lush. What was the consequence on the child of this exploration?

Sir Edward Marshall Hall. It left a wound which was apparent at the post-mortem examination. (To the Witness.) Where is the needle? (Same produced.) Was it an ordinary hypodermic needle?—No, a specially long needle.

That is introduced where, here? (Indicating.)—Yes.

Then it is drawn out and if there is any fluid you draw it out with the backward turn?—Yes.

If there is no fluid it comes out dry?—Yes.

Mr. Justice Lush. Would that do any harm?—None whatever.

Sir Edward Marshall Hall. You think none whatever?—I am sure.

I suppose in this case it did no harm because the child was moribund?—It would not have done harm in any case; it is a thing which is done every day.

And a mistaken diagnosis in diphtheria is done every day, is not it?—I do not know anything about it.

Have you taken the trouble to look at the reports? Do you know that in the London area alone in 1923 there were 2000 wrongly diagnosed cases of diphtheria sent to one hospital?—I have heard that.

It is in the Registrar-General's report?—That is not my affair.

Mr. Justice Lush. You know it is right?—I do not know anything about it; I do not dispute it.

There are a large number of wrongly diagnosed cases?—I do not know anything about it.

Sir Edward Marshall Hall. The report says: "Summary of all cases admitted with mistaken diagnoses in 1923 in the Fever Hospitals in the London area. Diphtheria or membranous croup 1985 wrongly diagnosed. 36 deaths."

Mr Vachell. Where there were no swabs taken.

Sir Edward Marshall Hall. How do you know; there is no evidence of that.

Mr. Vachell. You shall hear later.

Sir Edward Marshall Hall. (To the Witness.) Of course, you are a great believer in the antitoxin treatment?—Certainly.

Have you ever taken the trouble to study the Registrar-General's report on that alone?—No.

Do you know the number of deaths per million from diphtheria now are much higher than they were in 1876, 20 years before the antitoxin was discovered?—I do not know anything about it. I have not studied the statistics.

Mr. Vachell. I do not know if my learned friend would be content to wait till Sir William Willcox is in the box.

Mr. Justice Lush. I think it would be better.

Sir Edward Marshall Hall. Very well, I will wait.

Re-examined by Mr. Vachell.

There was, was there not, some epidemic in Gloucester in June of 1923?—Yes.

What was it?—Small-pox chiefly and a certain amount of chicken-pox.

Did Dr. Hadwen write a letter, which I see was inserted as an advertisement in the press, which dealt with that subject from the anti-vaccination point of view?—Yes, we have a print of that here. There are a number of things he says in that letter.

Mr. Justice Lush. If we are going into the anti-vaccination question we will do it to-morrow. I propose we should not do it at all. It is not necessary, is it?

Mr. Vachell. No, only this, that the suggestion here is that this gentleman——

Mr. Justice Lush. Dr. Ellis has intimated there was a very strong difference of opinion or difference of statement.

Mr. Vachell. And an attack upon members of the profession.

Sir Edward Marshall Hall. There was no attack on the profession.

Mr. Vachell. Yes, there was. (To the Witness.) There was this attack made and did you then yourself enter into some correspondence with Dr. Hadwen on the subject?—Yes, privately.

Do I understand that afterwards you were asked for certain information about Dr. Hadwen or that you volunteered it?—Yes.

What was it?

Sir Edward Marshall Hall. I understood him to say he was asked about a local report and he wrote to the London papers.—I was asked by three reporters. Three reporters came into my room asking for information, and before they went they said, "If you find out anything else you can oblige us with, we shall be glad."

Mr. Vachell. As a matter of fact were there some overtures with a view to making up your differences with Dr. Hadwen shortly before the illness of this child took place?—Yes.

And that was the position, was it, at the time that this child was taken ill?—Yes.

You were not present at the post-mortem examination yourself?—No.

So that all that you know about the child's condition, all you can tell is what you observed during its life?—Yes, clinically.

Mr. Justice Lush. If you are going into the question with Sir William Willcox or other doctors as to the effect of the antitoxin treatment, I will not ask Dr. Ellis anything about it, but I should like to ask some medical expert as to the time at which the antitoxin to be effective must be administered. The doctor said it was too late on the 9th.

Mr. Vachell. Sir William Willcox will tell your Lordship; I will postpone it and I will deal with it later.

Sir Edward Marshall Hall. I have left it, as my friend asked me to leave it, until Sir William Willcox came. I think you will find Dr. Washbourn quite competent to deal with it, but never mind now.

(*Adjourned to the following morning at* 10.30.)

Tuesday, October 28th, 1924.

Sir Edward Marshall Hall. My Lord, I have three or four medical gentlemen here whom I may or may not have to call, according to how the case develops. They are entitled to be in Court, but I understand they have not been allowed to come into Court.

Mr. Justice Lush. I do not quite understand on what principle people are sometimes kept out of Court and sometimes allowed in.

Sir Edward Marshall Hall. There was no application by my learned friend or I that the witnesses should be kept out of Court, and even if they are my witnesses, they are in the same position as Sir William Willcox who has been here instructing my learned friend.

Mr. Justice Lush. Certainly you are entitled to have them in.

Sir Edward Marshall Hall. That intimation from your Lordship is quite sufficient.

Mr. Justice Lush. They are expert witnesses.

Sir Edward Marshall Hall. Yes, they are not witnesses to facts at all.

Mr. Justice Lush. Yes, certainly.

Mr. Vachell. Your Lordship quite understands that no action on my part prevented it ?

Mr. Justice Lush. Nobody would think of saying so.

Mr. Vachell. I believe some of my witnesses have been out of Court.

Mr. Justice Lush. All your expert witnesses are entitled to be in Court.

Mr. Vachell. If your Lordship pleases.

DR. WILLIAM WASHBOURN, *sworn.*

Examined by Mr. Vachell.

What are your qualifications ?—Member of the Royal College of Surgeons of England and a Licentiate of the Royal College of Physicians of London.

I think you have a membership of one of the Orders ?—Yes, I have.

Which Order is it ?—C.B.E.

Companion of the Order of the British Empire ?—Yes.

Have you practised as a medical man in Gloucester for a number of years ?—I have.

For how long ?—Since 1885.

From 1885 onwards down to the present time ?—Yes.

Did you on the 12th August make a post-mortem examination on the body of this little girl, Nellie Burnham ?—I did.

Have you your notes there ?—Yes.

You are at liberty to refer to them if you desire to. Will you just tell us slowly and in detail what you found ?—The post mortem took place at 4.30 in the afternoon on August 12th. The body was poorly nourished and there was post-mortem staining on the skin of the dependent parts of the body. There was a puncture of the skin at the back of the chest on the right side which had been covered with gauze dressing. This puncture was such as might have been caused by an exploring needle. The back of the throat, the tonsils, the soft palate and the larynx were intensely inflamed, so much so as to be almost black in one or two places. There was an adherent patch of membrane the size of a shilling at the back of the epiglottis.

What was the nature of that patch of membrane you have spoken about ?—It was diphtheritic membrane.

That is the membrane characteristic or the symptom of diphtheria ?—Yes.

Diphtheritic you call it ?—Yes.

Show the Jury whereabouts the epiglottis is ?—Right at the back of the mouth at the top of the larynx ; you can just sometimes see the top of the epiglottis.

It is at the root of the tongue ?—Yes. The mucous membrane of both bronchial tubes was congested. The right lung was red and solid throughout from inflammation. It just floated in water.

That is the right lung ?—The right lung. The right bronchial tubes were completely filled with dense membrane, some of which was adherent and had evidently been formed in situ.

Mr. Justice Lush. What is the significance of that " formed in situ." What does it mean exactly ?—It means it had grown where it was found ; it had not come from elsewhere.

Mr. Vachell. What was the nature of that membrane that you found in the tube of the right lung ?—It was diphtheritic membrane. Above this adherent portion at the top of the largest bronchial tube was a loose piece of membrane which had apparently been inhaled from higher up.

A loose bit of membrane, what sort of membrane was that ?—It was diphtheritic membrane and in size it was about three inches long by one inch in diameter.

That was lying loose, was it ?—On the top of the other membrane which was adherent.

Then you say that that apparently had been inhaled. It had loosened from a place higher up and was lying where you found it ?—Yes.

Could you see any portion of the air passages from which that membrane was likely to have become detached ?—I think it must have become detached from the portion which I have already described which was intensely inflamed. It was too big to have come from the larynx alone, but in part it may have been attached to the upper portion of the larynx as well as to the inflamed portion of the throat.

What you call the inflamed area from which you think it may have become detached, would that be within sight if anyone looked into the child's mouth ?—Yes, some of it certainly would have been in sight—the back of the throat, tonsils, and soft palate.

How do you account for the character of these inflamed or raw spots ? Why should they be raw and inflamed ?—I think that is where the membrane had separated from, leaving an inflamed surface.

Mr. Justice Lush. You say that anybody examining the throat in the ordinary way in which a doctor does examine the throat would see that inflamed part ?—Yes.

And therefore would see the membrane before it was detached ?

Mr. Vachell. Yes.

The Witness. The left bronchial tubes were slightly congested as also was the trachea which we call the windpipe. In the right pleural cavity there was a small quantity of fluid.

Is that at the base of the lung ?—Yes, there was a small quantity, somewhere about three ounces, of clear fluid. The left lung was what we call emphysematous, that is to say, unduly distended, because it had to do the work of two lungs in fact.

Mr. Justice Lush. That would naturally come from any pneumonic condition ?—Yes. The heart appeared to be normal. Its cavities were not unduly distended. The stomach, liver, intestines, and kidneys appeared to be healthy. There was no membrane in the stomach. As regards the brain the vessels were slightly congested. In other respects it appeared to be normal.

Mr. Vachell. Did you form an opinion as to the cause of death ?—I did.

What is that opinion ?—My opinion is that death was due to diphtheria and pneumonia.

Is that an opinion that you can express with confidence ?—Yes.

You are, are you not, the appointed bacteriologist for the city ?—I am.

Is it your duty to examine swabs which may be submitted to you ?—Yes.

Did you receive from Dr. Ellis on the 10th August, that was the Sunday, I think, a swab which he delivered to you, taken from the throat of this child ?—I did.

Sir Edward Marshall Hall. I am not objecting here except because I think we are getting on very dangerous practice. Your Lordship knows the enormous amount of care that is always required in the case of an exhumation to prove that the articles examined by the bacteriologist are the identical articles that have been taken from the body of the dead person who is the person in respect of whom the charge is made. I am not throwing the slightest doubt on the honesty or integrity of this gentleman, or Dr. Ellis, but we ought to have some proof as to the identity of the swab examined other than merely the *ipse dixit* of these gentlemen, such as one doctor saying, " I handed it," and the other saying, " I examined it."

Mr. Justice Lush. I quite appreciate that point.

Mr. Vachell. Not from the dead body ; from the child, of course, when it was living.

Mr. Justice Lush. I know, but Sir Edward's point is, I suppose, that many swabs may have come, and Dr. Washbourn may have, for all that appears from the evidence, have confused the evidence.

Sir Edward Marshall Hall. I submit in a criminal case of this kind it is necessary to prove that the swab examined by Dr. Washbourn was the identical swab that came from the throat of the child Nellie, and that can only be proved by saying, " I took that swab and handed it personally to Dr. Washbourn."

Mr. Justice Lush. I suppose if you insist we must go into it.

Sir Edward Marshall Hall. I will get an assurance from Dr. Washbourn as to how it came.

The Witness. May I put it in my own way. I received a swab marked " N. Burnham " from Dr. Ellis. It was marked in that way.

Sir Edward Marshall Hall. Did Dr. Ellis give it to you ?—He did not.

Mr. Justice Lush. What date was that ?—On the 10th August.

Sir Edward Marshall Hall. Did Dr. Ellis give it to you ?—He did not hand it to me himself, as far as I remember.

Mr. Justice Lush. Who did hand it to you, do you know ; how did you get it ?—It would probably have been left at my house by a messenger.

Mr. Vachell. Did you receive any other swab on that day ?—I do not think I did, but I have not got my notebook here with regard to swabs. Probably the medical officer of health would be able to tell you whether any further swabs were sent to me. I do not think I did on that date.

Did you receive any other swab on that day marked " N. Burnham " ?

Mr. Justice Lush. That is not conclusive even if he did not.

Mr. Vachell. Not conclusive, but it is a step towards it.—I only received one swab marked " N. Burnham."

Mr. Justice Lush. Before we go further, you cannot at present, of course, throw any further light upon the identity of the swab.

Mr. Vachell. Not until I have had Dr. Ellis recalled.

Mr. Justice Lush. I was going to suggest that, if Dr. Ellis would come back.

DR. EDGAR SEVERN ELLIS, *recalled.*

Further Examined by Mr. Vachell.

Did you take the swab from this child's throat yourself ?—I think so, I almost always do.

Mr. Justice Lush. I thought yesterday you said you did ?—I do not remember any occasion when I have not.

Cannot you give us a definite answer ?—Yes, I think I can ; I took it myself.

I thought yesterday you said it ?—Yes, I am sure I took it myself.

Have you any sort of doubt now ?—No, not at all.

Why did you say you thought you did ?—I do not remember the exact occasion.

Sir Edward Marshall Hall. Then I submit this cannot be evidence.

Mr. Vachell. You know the swab I am referring to, the swab that was taken from this child Nellie Burnham's throat on Saturday the 9th ?—Yes.

Mr. Justice Lush. You were the only doctor there ?—Yes.

Who but you could have taken it ?—I do not think anybody could have. I might have sent a servant, but I do not recollect the occasion.

Mr. Vachell. First of all, when I say taking the swab what I meant to say was applying your swab to the throat ?—Yes, I took the swab.

In that sense ?—Yes.

Mr. Justice Lush. I thought there was no doubt ?—No doubt whatever. I took the swab.

Mr. Vachell. I used perhaps an unfortunate term in saying " taking it." The doctor thought I meant conveying it ?—I took the swab.

You put it into the child's throat, and you took it in that sense ?—Yes.

Having taken it what we want to know is what did you do with it next ?—I took it to Dr. Washbourn the next morning. I delivered it at the house, as far as I remember.

Mr Justice Lush. You yourself ?—As far as I remember.

Mr. Vachell. Did you place a mark upon it ?

Sir Edward Marshall Hall. I object ; that is not evidence. That is evidence of a written document. I object to the evidence of what is written on a document not produced.

Mr. Justice Lush. I do not think you can.

Sir Edward Marshall Hall. My Lord, we have had this over and over again in these cases, where the medical men themselves hand sealed jars to officers and officers take the sealed jars to London and hand them to Mr. Webster or the particular person in the sealed condition, and it is insisted that they are proved. Here the evidence is : " I took a swab in the sense I took it from the throat, and I caused it to be conveyed, or I think I took it myself ; I may have sent a servant who left it at Dr. Washbourn's house."

Mr. Justice Lush. The point we are on now is whether he can tell us what he marked upon it.

Mr. Vachell. I did not ask him that. I said : " Did you place a mark upon it ? " and that is the question objected to.

Mr. Justice Lush. I do not know that Sir Edward objected to the witness telling us what he marked.

Mr. Vachell. That he has not been asked. The answer is yes or no.

Mr. Justice Lush. We will go by very gradual stages.

Mr. Vachell. Did you place a mark upon it ?—Yes.

Mr. Justice Lush. May I ask what that mark was ?

Sir Edward Marshall Hall. No, I submit not.

Mr. Vachell. I do not wish to take any advantage of my learned friend.

Mr. Justice Lush. You would be very clever if you did that.

Sir Edward Marshall Hall. This is not a matter only of this case. A man's life might depend upon this answer, and I submit in law there can be no question about it. Asking what was marked on the parcel, which was some sort of written mark placed upon it obviously—the wrapper of this swab, because it could not have been placed on the swab itself—cannot be evidence, because it is giving evidence of the contents of a written document which is not produced.

Mr. Justice Lush. The written document may be destroyed. What became of the wrapper. Did you receive the swab wrapped up in something ?

Dr. Washbourn. They usually come in a glass tube. This was in an envelope, and on the outside of this envelope is the identification.

Mr. Justice Lush. What became of that envelope ?

Dr. Washbourn. It is destroyed ; always destroyed.

Mr. Justice Lush. I think you should preserve them. I think it would be wiser.

Sir Edward Marshall Hall. That is not the point. If the importance which is now attempted to be attached to this swab had been realised at the time when the swab was taken and examined every bit of identifying evidence should have been preserved.

I wish now to say that I object to this evidence because it does not sufficiently identify. I am not questioning Dr. Washbourn's bona fides in the slightest. This is not a question of a technical point. As your Lordship knows, in a criminal case no admissions can be made, and the prosecution have to prove the case strictly. I submit there is a hiatus in the identification of the swab examined with the swab taken, and as long as that exists you cannot have the evidence of what that swab contained.

Mr. JUSTICE LUSH. Surely that is not so. If the envelope with the mark on it has been destroyed surely you can give secondary evidence of what was on the envelope.

Sir EDWARD MARSHALL HALL. You can if it was last in my possession. You could give me notice to produce it, and in the absence of production then you could give secondary evidence.

Mr. JUSTICE LUSH. Take the ordinary case of the contents of a letter that has been destroyed and no copy kept. You can always allow evidence to be given of what it contains, because it is the best evidence that can be got.

Sir EDWARD MARSHALL HALL. Yes, if it is alleged to have been received by the person charged, or a party to the case. I agree if this swab had been handed to Dr. Hadwen with a mark upon it, and the wrapper which contained that mark was not produced I should not attempt to argue before a judge of your Lordship's experience that it would not be admissible to give evidence of the contents, but here is a swab delivered to somebody of whom I know nothing. Why I am insisting upon this point is because one of my grievances in this case—not against the Public Prosecutor because he was not then engaged in the case—on behalf of Dr. Hadwen, is that when they had decided to have a post-mortem examination, knowing what the charge was, they did not give Dr. Hadwen an opportunity of being present.

Mr. JUSTICE LUSH. That is quite a different point.

Sir EDWARD MARSHALL HALL. Therefore I insist upon what I conceive to be my legal rights subject to your Lordship's ruling, and I do submit strenuously that having regard to the fact that there is no sufficient positive identification of the swab examined by Dr. Washbourn with the swab taken from the child's throat, therefore Dr. Washbourn's evidence as to what he found in that swab is not, strictly speaking, admissible in this case. That is my point, and whatever your Lordship's intimation is I shall, of course, accept it at once.

Mr. JUSTICE LUSH. Do you press it?

Mr. VACHELL. No, my Lord, I do not particularly care. Of course, I put it forward as confirmatory evidence that the child was suffering from diphtheria.

Mr. JUSTICE LUSH. You see if you cannot get the evidence in as to what the result of the examination of the swab was it is no good. You rely upon that as confirmatory evidence, but you cannot get the evidence in unless you properly identify the swab.

Mr. VACHELL. That I realise, but what I was saying was that that is the only value of it. If I was in a position to prove the identity that would be the only value of it. It does not at all dispose of the question as to what this child died of. It is only a small item.

Mr. JUSTICE LUSH. Do you abandon it?

Mr. VACHELL. I will.

Mr. JUSTICE LUSH. I do not invite you to. I have not yet ruled on it. Do you want me to rule upon it?

Mr. VACHELL. I should prefer your Lordship to do it, but I have nothing to argue on the subject.

Mr. JUSTICE LUSH. I did not ask you to argue; I asked you to tell me whether you wished me to rule upon it.

Mr. VACHELL. My Lord, I do. I will take your Lordship's ruling.

Mr. JUSTICE LUSH. Well, I think it is admissible. You told us that the envelope was destroyed?

Dr. WASHBOURN. Yes.

Mr. JUSTICE LUSH. Sir Edward will have the benefit of the note of my decision in case it is wrong.

Sir EDWARD MARSHALL HALL. I felt I should not be doing my duty if I did not take the point.

Mr. JUSTICE LUSH. You are quite right to take the point.

Mr. VACHELL. Will you tell us what mark you put upon the envelope?

Dr. ELLIS. No, I cannot swear to that; presumably I put the name of the patient.

Mr. JUSTICE LUSH. That will not do, that you presumably did it?—I always do put the name of the patient, that is all I know. I cannot remember actually.

If you always did, you did it then?—Yes.

Yes, but do you always?—Yes, precisely, invariably.

The initials or the name?—The name. I may put N. Burnham; I may not have put Nellie.

Mr. VACHELL. That is all I want to ask you.

DR. WILLIAM WASHBOURN, *recalled.*

Examination continued by MR. VACHELL.

You told us, I think, what marking there was on the envelope of this swab?—Yes.

Did you submit the swab to bacteriological examination?—Yes, I did.

With what result?—The Klebs-Loeffler bacillus was present.

Sir EDWARD MARSHALL HALL. May we call it the K.-L. bacillus?

Mr. VACHELL. I am calling it throughout diphtheria bacillus. Is that the same as diphtheria bacillus?—Yes.

In your opinion was this pneumonia that you discovered in the body of the child secondary to the diphtheria?—I considered that it was a lobar pneumonia, and I believe it to have been secondary to the diphtheria.

Did you receive about this date—you will give me the exact dates—certain swabs from the Medical Officer of the Isolation Hospital, Dr. Berry?—I did.

Will you just give us the dates?—On August 12th one marked " Mrs. B."

Sir EDWARD MARSHALL HALL. *De bene esse* I do not object?—And also one marked " L. B."

Mr. JUSTICE LUSH. Both on the same date?—On the 12th August. Both of these proved to be negative; the Klebs-Loeffler bacillus was not found. On August 13th I received a swab from the City Hospital marked " G. B."

Mr. JUSTICE LUSH. These envelopes were destroyed, I suppose, like the last?—All destroyed. In this case the Klebs-Loeffler bacillus was present.

Sir EDWARD MARSHALL HALL. You call that positive?—Positive.

Mr. VACHELL. On the 11th did you receive one?—On the 11th I received a swab marked " H. Burnham " from Dr. Graham.

Mr. JUSTICE LUSH. We are going far afield. Are you going to pursue each one of these cases, because it will take a terrible time, and it has a very small bearing upon the question, has it not?

Mr. VACHELL. This was the last one.

Mr. JUSTICE LUSH. If we have to consider these at all we shall have to go carefully into each one of them, get at the history of the case, and all the rest of it, because we cannot do it in a cursory way if we do it at all. I should have thought you might jettison that.

Mr. VACHELL. Certainly, I will accept your Lordship's suggestion.

Mr. JUSTICE LUSH. You know better than I, of course, the importance of it.

Mr. VACHELL. This is the last one, and we have got half that, and then I say no more about it.

Sir EDWARD MARSHALL HALL. It will involve calling Dr. Graham, of course.

Mr. JUSTICE LUSH. Can you not content yourself with the evidence that bears directly on the case of this child Nellie.

Mr. VACHELL. Yes, my Lord, I think I will.

Mr. JUSTICE LUSH. Still you know more than I do about the importance of it.

Mr. Vachell. There is only just this one question that I am now in the course of putting. I was not going to put any more to Dr. Washbourn on the subject. He says on the 11th August he received a swab from Dr. Graham marked "H. Burnham." I was only going to ask what the result was there, and then there is an end of it.

Mr. Justice Lush. Do you object, Sir Edward?

Sir Edward Marshall Hall. Only in the comprehensive objection—if I am wrong upon the other.

Mr. Vachell. What was the result of the examination of that?—That swab was positive.

Cross-examined by Sir Edward Marshall Hall.

Of course, again subject to my objection, let me clear this up. It is all subject to my objection. "Mrs. B.," does that mean Mrs. Burnham, as far as you know?—I have no idea what it means.

From whom did you receive that swab?—That swab came from the Medical Officer of Health.

Dr. Berry?—Yes.

The one marked "L. B."; do you know to whom that referred?—No.

It came from Dr. Berry?—Yes, I have heard since, but I did not know at the time.

Having heard since that that in fact referred to the boy, Leonard Burnham?—Yes.

I will accept that for the purpose. Therefore in the case of Leonard Burnham, who had had identically the same throat late in July and had been apparently cured by Dr. Hadwen, his swab was negative?—It was.

As to the other one, "G. B.," you do not know who that is. That was from the City Hospital, not Dr. Berry?—It is practically the same thing, because Dr. Berry is the doctor to the hospital.

And as to the other one, "H. Burnham," were you told afterwards that that was Hilda Burnham?—Yes, I think I was.

And that was positive?—Yes.

You have already said this morning that in your opinion this was a case of lobar pneumonia, but you thought it was secondary to the diphtheria?—I did.

Would this be right to say, that except for a certain amount of compensatory emphysema the left lung appeared normal?—Yes.

Mr. Justice Lush. Emphysema is a common complaint?—I take it it is bound to occur in such a case.

In which case?—In which the other lung is so involved that it is out of action.

Sir Edward Marshall Hall. If the right lung was out of action you would expect to find emphysema in the left?—Yes.

Almost of necessity?—Yes.

Therefore that was a symptom that was entirely conditional on the state of the right lung?—Yes.

There was some congestion of the left bronchial tubes as well as the trachea?—Yes.

The condition of the right lung was that of lobar pneumonia of recent date?—Yes.

Not more than two or three days?—I think so.

I do not want to put it in for purposes which my Lord will appreciate, but as a matter of fact you are entitled to look at that for yourself. (Document handed to witness.) Is that your writing. I do not put it in; I only want you to look at it. Will you read it to yourself, not out loud. Having read that, I ask you again, have you any doubt that the condition of the right lung was that of lobar pneumonia of recent date, not more than two or three days?—I believe it to have been so.

Sir Edward Marshall Hall. I hate mysteries in these cases.

Mr. Justice Lush. I do not know. I should like to know what is being submitted to the witnesses.

Sir Edward Marshall Hall. (To the Witness.) What I submitted to you was a letter of your own?—Yes.

Mr. Justice Lush. I wish you would ask what makes him think that the lobar pneumonia coincides in time with the 7th August.

Sir Edward Marshall Hall. I am going to develop that a little later; of course, it is the sheet-anchor of my case, but for the moment I have to get the atmosphere before I go to that. (To the Witness.) Did you know Dr. Ellis at all before this swab was sent to you?—Yes, he has been a personal friend for years.

What did you do first; did you examine the swab before you made the post-mortem examination?—Yes, before I knew anything about the case.

When you examined the swab, did you know in point of fact that the child from whom it had been taken was dead?—I did not.

Can you give me—this, of course, is all subject to my objection—the time of day on the Sunday when you examined the swab?—It was probably in the morning.

You cannot say better than that?—I do not think the report would have been received till the Monday morning.

Did you yourself do the bacteriological examination or one of your assistants?—I did it myself.

You take a smear and put it under the microscope?—I made a culture on the Sunday and that culture would not have been examined till the Monday morning.

If you had to make a culture it would have to wait till the Monday?—Yes.

Mr. Justice Lush. I was going to ask how long it took to make a culture and then get a result.

Sir Edward Marshall Hall. They vary with different germs?—In this case 12 to 14 hours is usually sufficient.

And you made yourself the microscopic examination in the morning?—Yes.

And you found then what is known as the Klebs and Loeffler bacillus?—Yes.

Two people are supposed to have diagnosed this, Mr. Klebs and Mr. Loeffler?—Yes.

And ever since that bacillus has been discovered it has been recognised in the medical profession by a large majority, I will not say universally, as being the specific bacillus of diphtheria?—It is.

But you agree, do you not, that it can be found in cases where there is no diphtheria?—It can in certain unusual cases.

In healthy children?—Sometimes.

And even in inanimate objects?—Yes.

I take it for the purposes of your answer that the very large majority of the medical practitioners of this and other countries are of opinion that it is the specific bacillus of the disease, diphtheria?—Yes.

Diphtheria meaning, of course, from its derivative sign of "diphth," which is Greek for a membrane, is it not?—Yes.

So it is called diphtheria because it is membranous?—Yes.

Did you see Dr. Ellis at all before you made the report upon the swab?—I did not.

When did you first know that that was a swab taken from a patient attended by Dr. Hadwen?—At the time I made the post-mortem examination.

Not before?—Not before.

When you examined the swab you did not know the patient from whom the swab had been taken?—I did not.

Nor the name of the medical man who had been attending the patient?—No.

When did you know of the death of Nellie?—At the time I was asked to make the post-mortem examination, I think on the afternoon before. I think that would be the Monday.

Was it the Sunday or the Monday that you were first told of the death of Nellie?—I am not quite sure. Was Monday the 11th?

Monday was the 11th?—Then it would have been on Monday afternoon in the Coroner's office they came to ask me about the post-mortem examination.

And you did, in fact, make the post-mortem examination on the 12th?—Yes.

About what time on the 12th?—About 4.30.

So 24 hours elapsed between your receiving the notification that a post-mortem was required and the actual making of the post-mortem examination ?—I think so.

And when you received the notification of the necessity for the post-mortem examination, you were also informed that the child had been a patient of Dr. Hadwen's ?—I am not quite sure that I heard that when I was asked to make the post-mortem examination or when I arrived at the post-mortem room.

But you knew it before the post-mortem examination ?—I certainly knew it before I started to make the post-mortem examination.

And did you know that there was, at any rate, any suggestion or a charge of negligence as against Dr. Hadwen in the treatment of this particular case ?—Yes.

The post-mortem examination was of vital importance as affecting a suggestion of that kind, was it not ?—Yes, in a sense it was.

Obviously, and I think you asked Dr. Bell to be present at the post-mortem examination or did he ask to come ?—I did not ask him to be present, but he was present.

He was in fact the Deputy Coroner ?—Yes.

He is a medical man ?—Yes.

He is also the official doctor of the prison ?—Yes.

He was Deputy Coroner and at that time he was Acting Coroner, was he not, because the Coroner was away on his holidays ?—I think he was.

And Dr. Bell was a gentleman whose name had been very prominently before the public in connexion with the unfortunate antivaccination dispute of the previous year. He was Chairman, was he not, of the Committee after Dr. Hadwen resigned ?—Not to my knowledge.

Then do not take any notice of that. Dr. Bell was present not at your invitation but I suppose as of right, being in fact for the moment Acting Coroner ?—Yes.

Did you suggest to anyone that Dr. Hadwen ought to be given an opportunity of either being present at the post-mortem examination or having some medical man to represent him ?—I think I asked Dr. Bell if Dr. Hadwen was going to be present.

From a gentleman of your reputation in this city may I say that is what I would have expected from you. Here you knew there was going to be, or might be, a very serious charge at any rate of negligent treatment; I am not going as far as a criminal charge of manslaughter. But there was the possibility of a charge of negligent treatment being preferred against a doctor in the town, a qualified medical man, in respect of the death of a child whose body you were going to examine post mortem ?—That is so.

But you think, as I think every fair-minded man would think, that at any rate he ought to have had an opportunity of either being present or being represented ?—I wondered why he was not there; I fully expected to see him there.

Mr. JUSTICE LUSH. You say you asked the question ?—I did.

Sir EDWARD MARSHALL HALL. You would not wonder now if you were told and you accepted the statement that Dr. Hadwen was never even informed of the death of the child until half an hour before the nquest was being held ?—No.

Mr. JUSTICE LUSH. Did you get an answer to your question ?

Sir EDWARD MARSHALL HALL. Did Dr. Bell give you any answer as to why he was not present ?—I think he said that Dr. Hadwen had not been invited; anyhow that he was not coming.

I want now to come to the point my Lord asked about. Whilst the post-mortem examination is being made, of course the portions that you are examining are excised from the body ?—They are.

Amongst other portions, did you take out this right lung ?—I did.

For the purpose of testing whether it would float n water or not; that was to test its density ?—Yes.

And did you find, as far as you could find, that it was practically solidified ?—Yes.

And did you call Dr. Bell's attention to the fact, as the lung lay on the post-mortem table, that it had arrived at the state of red hepatisation ?—I did.

And did you go on very carefully, and most fairly, also to call his attention to the fact that what is known as the state of grey hepatisation had not yet supervened ?

Mr. JUSTICE LUSH. What is the significance of that ?

Sir EDWARD MARSHALL HALL. That the red hepatisation was present, but that the lung had not yet arrived at the state of grey hepatisation. The only importance of it is this: Is there any other condition, I mean if you were right in your diagnosis of the red hepatisation, and also in your negative diagnosis that the grey state had not arrived, is there any state of pneumonia, except lobar pneumonia, in which you would find those two conditions ?—Yes, in the first of the conditions, red hepatisation.

Where do you find it ?—In lobular pneumonia you have appearances which are practically identical with the red hepatisation of lobar pneumonia.

But you never find the grey hepatisation ?—No.

Mr. JUSTICE LUSH. You must explain.

Sir EDWARD MARSHALL HALL. You might find in some conditions of lobar pneumonia red hepatisation, but you never will find grey hepatisation.

Mr. JUSTICE LUSH. In lobular ?

Sir EDWARD MARSHALL HALL. In lobular.

Mr. JUSTICE LUSH. This was not lobular ?

Sir EDWARD MARSHALL HALL. He has not said that for one moment. Having had your attention called to the actual condition of the body, the lung itself, you formed the opinion that it was lobar pneumonia of probably two or three days' duration ?—I did.

Is lobular pneumonia a well-known consequential condition of chill acting upon an enfeebled vitality ?—A consequence.

And the more enfeebled the vitality, the less the quantity of chill required to create a pneumonic condition ?—I take it that is so.

Mr. JUSTICE LUSH. That is to say, you more readily take it if you are enfeebled than if you are robust ?

Sir EDWARD MARSHALL HALL. Yes. (To the Witness.) We are told, upon what is now not questioned evidence, that on the evening of the 7th this little girl, who had been for days in bed suffering, at any rate, from a serious affection of the throat, had got out of bed, gone downstairs in her bare feet and nightgown, had gone to the scullery, and got a drink of water; you have heard that ?—Yes.

Will you accept that as true ?—Yes.

That the child then returned to bed. We have no evidence as to how long she took going back, but she returned, and the following morning she was seized with the first attack of vomiting; you have heard that ?—Yes.

Is not one of the first evidences of pneumonia, or the on-coming of pneumonia, in a case like that, vomiting ?—No, I do not think it is; the usual first onset is a shivering attack.

Yes, I do not say it is absolutely the first, but amongst the early symptoms of, shall we call it, a chill, pneumonia, is not vomiting one of the best recognised ?—No. I do not think it is.

I would suggest to you that is not capable of challenge on the point of view of the present existing medical authorities, but if you say that is so I must go into it. Dr. Ellis agreed with it. After Dr. Ellis's answer I did not think it would be challenged, because there was no re-examination.

Mr. VACHELL. I said I would leave these matters until I came to Sir William Willcox, and you agreed.

Sir EDWARD MARSHALL HALL. Would you prefer I should leave that. Have you made a great study of what are the earlier symptoms of pneumonia ?—I have looked up some of the authorities, and I cannot find any reference to vomiting as an early symptom.

If it is not one of the first symptoms, what would you say about vomiting suddenly supervening on this morning following this visit downstairs, would you have attached any importance to it ?—Vomiting is so extremely common in diphtheria, especially in severe diphtheria, that I should have expected it.

Would you then think that if there was no vomiting in a case of suspected diphtheria that probably it was not diphtheria ?—No, all that would have indicated was that probably it was not a serious case of diphtheria.

But surely if it was diphtheria it was diphtheria from the first ?—Certainly.

The mother tells us the child was first taken ill on the 28th of July. Then if this was, in fact, diphtheria that the child was suffering from, it was diphtheria on the 28th July ?

Mr. Justice Lush. The 30th July was the date we had.

Sir Edward Marshall Hall. Call it that. It was diphtheria on the 30th ?—Yes.

If there, in point of fact, had been no vomiting between the 30th of July and the 8th of August, and vomiting is a very common sign of diphtheria, would not you say that the absence of vomiting was also a very useful factor in diagnosing that this was not diphtheria ?—No, I do not think vomiting is sufficiently characteristic for it to be of any great significance in the diagnosis of diphtheria.

Therefore, if that is the correct answer, that it is not of sufficient importance, would not you think that if it supervened on the eighth day, or the ninth day, that it was due to some other cause ?—No, because although it is not of importance in the diagnosis of diphtheria, it is of extreme importance as regards the prognosis, that is the outlook of the case of diphtheria.

Mr. Justice Lush. Is this what you mean : If there is no vomiting, although it is not characteristic, and therefore indicative of the disease, yet it is a hopeful sign as to the result of the illness ?—That is so.

Sir Edward Marshall Hall. If it suddenly supervened on the eighth day, what do you say then ?—It is a serious indication.

And one that ought, at any rate, to have been communicated to the medical man at once ?—Certainly.

And whilst I am on the question of diphtheria for the moment, is not the swelling of the cervical glands one of the most important indications of diphtheria ?—It is an indication of a very severe case, but it does by no means always occur, even in severe cases. In this case it was not present.

There was no swelling of the cervical glands at all ?—At the post-mortem no swelling.

Dr. Ellis has told us there was a slight swelling, but it was not noticeable. The post-mortem showed no sign of it. It had disappeared at the post-mortem ?—A very slight swelling would disappear.

I am rather stressing this. Do not the medical profession attach great importance to the swelling of the cervical glands when it is present ? They are *these* glands (indicating) ?—The glands under the jaw.

Would you think that a medical man was justified in assuming that when he found no swelling of the cervical glands that he might assume it was not diphtheritic ?—No, I am afraid I cannot go as far as that.

Mr. Justice Lush. I wish you would ask, at some stage, whether he says that vomiting is not characteristic of diphtheria, or if a chill sets up pneumonia, leaving out the diphtheria, whether he would expect vomiting to supervene ?

Sir Edward Marshall Hall. If you get pneumonia, superadded to diphtheria, you would certainly expect vomiting, would you not ?—Possibly, because the pneumonia would tend to make the diphtheria worse.

Mr. Justice Lush. The pneumonia ?

Sir Edward Marshall Hall. Would aggravate the diphtheria ?—Or, put it in another way, the condition of the patient worse.

I was going to put it in a different way still, that a case of diphtheria, which in all probability was on the road to recovery, might be converted into fatal diphtheria by a chill and pneumonia ?—By pneumonia, yes.

I want to deal for a moment with this membrane. You say the membrane you found was undoubtedly diphtheritic. Did you examine the membrane microscopically ?—I did not.

There are many kinds of membrane ?—There is no kind of membrane resembling the diphtheria membrane, so far as I know.

It may be that you have a marvellously trained eye, but surely you, being a bacteriologist, and therefore not hampered by any disbelief in bacteriology, the only final test, so far as you are concerned, would be a microscopical examination of the membrane ?—I think it was absolutely clear, without a microscopical examination.

You thought it was so clear, and not necessary to examine ?—I did.

Does this bacillus cause the membrane ?—In a sense it does.

And would it be present in enormous quantities in the membrane ?—It would.

And is it only in the membrane that you would expect to find the bacillus, or would you find it in the surrounding tissues ?—You would find it in the surrounding tissues, in all probability.

This membrane you described as having sloughed off, must have sloughed during life ?—Yes.

It could not slough off after death, that is quite obvious ?—No.

I take it that within a quarter of an hour of a child's death, under conditions that have been described, there would not be sufficient vitality in the child to eject, by the mouth, any large piece of membrane ?—I really could not answer that question.

You would think it highly improbable, would not you ?—No, I think it is quite possible she might have brought it up.

The membrane you found might have been in such a position during life as to have been invisible to anybody examining the child by the mouth ?—I do not think it could have been, because of its size.

Is one of the most cogent signs of diphtheria, as contra-distinguished to any other diseases of the throat, a sort of yellow pallid colour at the back of the throat itself ?—Do you mean apart from the membrane ?——

Yes ?—No, I do not think it is.

If you get a very red appearance at the back of the throat the probability is that the disease is not diphtheria ?—I do not think the appearance of any particular significance.

Have you had much personal experience of diphtheria cases in your profession ?—Yes, I have had a reasonable experience both in hospital and in private.

About how many cases of diphtheria do you think you personally have seen ?—I should think 300 or 400.

In the course of your practice ?—Yes.

You agree, do you not, that at any rate the epiglottis is invisible ?—Yes.

If there was membrane on the epiglottis even a proper examination, unless you had a laryngoscope, would not enable you to see it ?—You would not.

And you could not use a laryngoscope in the case of a child as ill as that ?—No.

Mr. Justice Lush. Supposing you examined the throat of a patient and you find nothing but red inflammatory symptoms and no white patch at all, you would not then assume there was any real danger of its being a diphtheritic case, would you ?—I think you would, and I think in such a case it would be wiser to proceed to further measures to clear up the diagnosis.

If all you saw was a red throat ?—Yes.

Sir Edward Marshall Hall. May I put it like this, that at the present moment so many of the members of the profession have such a belief in the diphtheria germ that in practically any condition of sore throat which is not absolutely obvious they will take a swab and administer antitoxin; is not that the sort of general practice ?—Yes.

On this ground, that if it is not diphtheria it can do no harm; if it turns out to be diphtheria it may do good ?—Yes.

Mr. Justice Lush. That is the counsel of perfection, is not it ? I thought most people if they saw a throat only red they only gargled it; is not that so ? —Yes, I think so unless the patient is ill.

Mr. Justice Lush. I mean unless there are some other symptoms.

Sir Edward Marshall Hall. Do you agree that acute follicular tonsillitis is a condition that it is very difficult to diagnose or do you think it is easy ?—In some cases it is impossible to diagnose without bacteriological examination.

It may be so, like diphtheria, unless you have a bacteriological examination, that you cannot say for certain ?—I do not agree.

The condition of the stomach, kidneys, liver, and intestines was all healthy ?—Yes.

The heart was healthy ?—To the naked eye.

I take it your examination of the lung was by the naked eye ?

Mr. Justice Lush. Our eyes are naked; there are no other ways of looking.

Sir Edward Marshall Hall. As far as you could judge, the heart was healthy ?—Yes.

I am not suggesting your opinion is wrong or saying it is wrong, but that is a condition which is more or less inconsistent with an acute diphtheritic condition, is it not, if the heart is all right You would expect fatty degeneration, would not you ?—In a great many cases there would be fatty degeneration, but by no means in all cases.

But there are cases in which the bacillus is not indicative of diphtheria.

Mr. Justice Lush. I did not appreciate that.

Sir Edward Marshall Hall. I know what is coming, but your Lordship perhaps may not have noticed it. He says the condition of the heart was normal. I will tell your Lordship now that Dr. Willcox is going to say it is impossible to say what is the condition of the heart unless you have a microscopical examination. I am challenging that when Sir William comes, but I am accepting the condition deposed to by Dr. Washbourn who saw the heart. The importance of it is this, that Dr. Washbourn agrees that in many cases of diphtheria you expect to find a condition of fatty degeneration of the heart, and if you do not find it, it is a factor. (To the Witness.) You agree in fairness to anybody that if the issue here was diphtheria or no diphtheria it would be one of the factors to be considered on the negative contention that in point of fact, as far as you know, the heart was normal. It is worthy of consideration; I do not put it any higher. It is worthy of consideration on the negative hypothesis ?—Yes.

The supervention of pneumonia indicates a febrile condition in the patient, does it not, of necessity ?—Yes.

Is it not a fact that every febrile condition in children on its immediate supervention creates a tendency to vomit ? You say shivering is the first. I say shivering and vomiting is the first indication of a febrile condition in a child ?—I do not think it is by any means universally so.

Would not you expect if a child was suddenly attacked and became febrile—never mind what the cause of the fever was—that that child would amongst its very earliest symptoms vomit ?—My answer is No. One frequently sees children who are feverish and who do not vomit.

I will only put it to you that one of the very first symptoms in children—have you had much experience of children ?—A fair amount.

Especially in children who are suddenly attacked with a feverish condition, is that you get shivering and vomiting ?—My answer is No.

Would you go so far as to agree you get it commonly ? —Yes, I will.

You have said that you found a condition of lobar pneumonia on the 12th August probably of two or three days' duration. Does that mean ante-mortem or at the date of the examination ?—Ante-mortem.

So that therefore that would be two or three days anterior to midnight of the 9th to 10th ?—Yes.

Do you realise that that fits in exactly with the admitted occasion of the night of the 7th when, at any rate, the child was exposed to the risk of the chill; I put it no higher than that ?—Supposing the pneumonia had been caused by that chill, therefore it would have begun to have manifested itself from 12 to 24 hours afterwards. There must be some interval.

I will give you your full 24 hours. If you give it 24 hours the pneumonia would begin to manifest itself, that is to say, it would be in a condition of activity by the night of the 8th, or by the evening of the 8th ?—Yes, I suppose it would. It fits in.

The child died about 36 hours after that; rather more, and you say two or three days ?—Yes.

It is consistent, is it not ?—It is consistent, but it is rather a tight fit.

I quite agree Dr. Ellis used the same word. May I put this to you, that it is impossible to absolutely eliminate it as the cause of the pneumonia ?—I agree.

And my friend, Mr. Clements, has reminded me of a question I was going to put to you. I think before the magistrates you said this, "I think the child had the pneumonia which I should expect to find following a chill" ?—I also agree.

Mr. Justice Lush. Then why, if that is so and the time does fit in, although the fit is a tight one, do you say you are still inclined to the view that the pneumonia was the sequence and was caused by the diphtheria instead of by the chill ?—Because I think it is much more likely to have been caused by what we know was present.

That is what I want to understand, your reasons for that, because you have the two possible factors. One is the diphtheria which does often set up pneumonia. The other is a chill which also very often sets up pneumonia. Why do you choose the one and reject the other ?—Because I think the one is the more probable.

Why, that is what I want to know ?—Because it is a so much more potent factor in the production of pneumonia.

But diphtheria cases do not ordinarily set up pneumonia ?—Yes, very frequently they do.

But not ordinarily ?—In severe cases. They very seldom die without some patch of pneumonia in one or other lung.

Sir Edward Marshall Hall. May I put it in vulgar parlance for a moment, that the odds are less against its being a sequela than for its being the result of a chill ?—No, I do not agree. I think the odds are in favour of its being a sequela.

I say there are less odds; it is longer odds against its being so, but at the same time you cannot ignore it ?—I cannot.

I think you said this also, "I cannot say if the child would have died if she had not had pneumonia."

Mr. Justice Lush. Did you say that ?—I did.

You cannot say that the pneumonia was not caused by the chill. It seems to follow that you cannot say that the child died from diphtheria; that is the logical sequence, is not it ? Will you deal with it because it is a very important part of the case, of course. If you cannot say that the child would have died but for the pneumonia and if you cannot say that the pneumonia was not caused by the chill, does not it seem to follow that you cannot say that the child died from diphtheria ?

Sir Edward Marshall Hall. That is the dilemma as I was putting it.

Mr. Justice Lush. I wanted to try to deal with that because it is an important question in the case.—It is a little bit difficult to express one's view, but I feel sure that the diphtheria was a very large determining factor in the death of the child.

That leaves it open still to the cause of the pneumonia. You think what was a large factor ?—The diphtheria.

Still the child might not have died, if it had been only diphtheria ?—She might not.

Sir Edward Marshall Hall. Do not you find a little difficulty in this case, because here is this child for eight days suffering from this disease, whatever it is, a disease of the throat, and no vomiting and no pneumonia until after she goes downstairs in this risky manner on the 7th. Does not that rather make you think that it was not diphtheria ?—No.

Not now that you have a swab, because nothing would make you believe this was not diphtheria, now, would it ; now you have had a swab which has had a positive reaction, you are certain it was diphtheria ?—That is not the reason I am certain it was diphtheria at all.

And the membrane ?—The post-mortem examination is the reason.

The membranous condition which you found, the condition of the child's body plus the bacteriological examination ?—Yes.

But apart from that, because Dr. Hadwen had not had a post-mortem examination and Dr. Hadwen had not had a swab, do not you think that the fact that vomiting had not supervened and no pneumonia had supervened as far as we know until the 8th day is an indication against diphtheria, apart from the rest of the case which we now know of ?—It is a very slight indication one way or another.

You do not attach much importance to it either way ?—No, I do not.

I will go on with what you said, " I cannot say if the child would have died if she had not contracted pneumonia." I say similarly as regards diphtheria the child may have contracted a chill by going downstairs on the 7th August which chill might have developed into pneumonia. That is what you said and you agree ?—Yes, and I stick to it.

" It is impossible for me to say what part the pneumonia played in this child's death. At the post-mortem the child had the appearance of having had lobar pneumonia. I think the child had the pneumonia, which I should expect to find following a chill. The pneumonia was consistent with having been contracted in two or three days before death," and you repeat it ; that is your evidence to-day ?—Yes.

Mr. Justice Lush. Read the last line.

Sir Edward Marshall Hall. " I think the child had the pneumonia, which I should expect to find following a chill."—Might I explain what I meant. I meant by the expression as regards the form of pneumonia that the child had lobar pneumonia.

Sir Edward Marshall Hall. You say this later, " The pneumonia I found is the kind I expect to find when a child has contracted a sudden chill " ?—Again I meant by that lobar pneumonia.

Mr. Justice Lush. You mean by that it was the lobar as distinguished from the lobular ?—Yes.

Sir Edward Marshall Hall. Do you really accept my Lord's suggestion ? Would not you much more expect to find lobar pneumonia following a chill ?—Yes.

Mr. Justice Lush. That is what I meant. That rather seems to put the weight on that side of the scale which points to the chill being the cause. If it was of that type, which you think it was which indicates a chill as the cause, I ask you again why, notwithstanding that, you still think that the pneumonia was not caused, although of the lobar type, by the chill which usually does produce lobar pneumonia ? Do you see what I mean ?—I think I see. The reason is that the right bronchial tubes were so exceedingly involved in membrane that the condition was such that it would be likely to set up the pneumonia.

Sir Edward Marshall Hall. But you have a unilateral pneumonia here, only one lung. If that was the result of infection percolating or coming down from the throat, is not it incredible it should not have affected both lungs instead of one ?—No, because it is only the right bronchial tubes that were involved in the membrane.

Mr. Justice Lush. That is what he said ; the right bronchial tubes, the right lung.

Sir Edward Marshall Hall. That is what Dr. Ellis said yesterday. But do not you expect as a rule in lobular pneumonia to find a bilateral condition ?—It is generally the case, but by no means always.

Is lobular pneumonia what they call catarrhal pneumonia ?—Yes.

Mr. Justice Lush. Lobular pneumonia is generally bilateral ?—Generally bilateral.

Sir Edward Marshall Hall. And lobular pneumonia is the sort of pneumonia that you would expect to follow diphtheria ?—It is the usual sort to follow diphtheria.

Re-examined by Mr. Vachell.

When you made the post-mortem examination you found, I understand, in the right bronchial tubes diphtheria membrane ?—I did.

That was growing ?—Yes.

You said something about some of the membrane was in situ. What effect would diphtheria membrane have upon the lung from growing down the tube in that way ; what would the effect be ?—It would block the entry for air into the lung to some extent, and it would cause the lung to become inflamed.

That means to say it would cause pneumonia ?—Yes.

Of what description might that pneumonia be ?—As a rule it is a bronchial pneumonia ; in other words, a lobular pneumonia, but occasionally, as I believe was the case here, it is a lobar pneumonia.

Did you see sufficient evidence of this diphtheritic growth into the lungs in your opinion to set up pneumonia ?—Yes.

Of either kind ?—Yes.

Mr. Justice Lush. Will you say that again ?—Sufficient membrane to set up pneumonia of either kind.

Of either lobular or lobar ?—Yes.

Mr. Vachell. Was there sufficient to account for the condition of the lung that you found ?—There was.

You have been asked something about this germ—this Klebs-Loeffler germ. It is found, as you told us, in healthy throats sometimes ?—It is sometimes.

If it is found in throats of persons who are suffering from sore throat, what do you say is the matter with that person ?—I say that that person is suffering from diphtheria in all human probability.

Mr. Justice Lush. What is it that would make you say that exactly ?—That the patient is suffering from diphtheria in all human probability.

Yes. I wanted you to tell me what would make you say that ?—The presence of the Klebs-Loeffler bacillus in a patient who is ill with a sore throat.

Mr. Vachell. I think you told my Lord that an inflamed or sore throat would in your opinion be indicative, I think you said, of diphtheria.

Mr. Justice Lush. I do not think the doctor went quite as far as that, did he ?—No, it would have been suggestion, I think ; I could not go further than that.

Mr. Vachell. If in addition to the sore throat you found that the patient has a blood-stained discharge from the nose, a highly offensive breath, headache and drowsiness, what do you say then ?—I should say that my suspicions would be very strongly confirmed.

What would be the proper treatment if you found all these things, the offensive breath, the peculiar discharge, and the red throat ; is there any treatment which you say that every reasonable doctor would apply in such circumstances ?—Assuming that the doctor had suspicions that it was diphtheria he should, in my opinion, have injected antitoxin.

He should, if he had suspicions, have injected antitoxin. Suppose he had not the suspicion, although these symptoms were occurring, what do you say then ?—Then I should think he should have proceeded to have had a bacteriological examination made.

Although he had not suspicions ?—Yes, even if he were not suspicious of diphtheria it would have been wiser with those symptoms.

He would, if not suspicious, have been wiser if he had a bacteriological examination. Could an ordinary careful and skilled doctor observe those symptoms and not have his suspicions aroused as to its being a case of diphtheria ?—I do not think he could.

Mr. Justice Lush. You do not think he could have avoided being suspicious ?—No. My reason for that is that diphtheria is the important throat illness which one should always be on the look-out for.

If in addition to the symptoms I have named membrane was visible from outside, what do you say then ?—I think that makes it a certainty that it is diphtheria.

Sir Edward Marshall Hall. If it is visible and is seen, because the mere fact that it is visible does not imply that it is seen.

Mr. Vachell. You may stop the child's mouth with your finger and prevent its being seen.

Sir Edward Marshall Hall. Or two fingers, so as to make it doubly certain you cannot.

Mr. Justice Lush. Is it possible to make a proper examination of the throat by merely inserting your two fingers ?

Mr. Vachell. One or two ?—I do not think it is really. It is a very clumsy method of procedure.

Mr. Justice Lush. My question was, do you think you could make a proper examination in such a way as that ?—I do not think you could be sure of making a proper examination.

Mr. Vachell. You saw at the post-mortem these raw patches, and those were visible from outside ?—Yes.

You also found this loose piece of membrane which you think had been taken lower down on to the top of the lungs ?—Yes.

Did you form an opinion as to where that loose piece came from ?—I thought it came from the inflamed patches in the throat.

If that was where that loose piece had been in situ, that is in the place where it originally grew, does it follow that that would be visible from outside ?—It would have been visible from outside.

Mr. Justice Lush. What would that follow from ?

Mr. Vachell. The doctor sees the raw patches where membrane has been.

Mr. Justice Lush. And if the membrane comes from that patch, and you can see the patch, you could see the membrane.

Mr. Vachell. Yes, that is what it really comes to. I may have put a question too many on it, but that is what it is. Then you have paid some little attention, have you, in the way of research to this question of vomiting, as to what that is a sign of ?—Yes.

You have consulted the authorities ?—Yes.

Is Osler one of the recognised authorities ?—Yes.

And, I suppose, one of the most modern ?—Yes.

Was that one you consulted or not ?—Yes.

And from what you have seen there is there anything to alter your view, that vomiting does not necessarily play a part in pneumonia ?—There is nothing.

The right lung, I gather, did just float ?—Yes.

That means just awash ?—Just awash.

The water just on the top of it ?—Very nearly the same specific gravity as water.

But you made no microscopical examination ?—No.

Without a microscopical examination do you feel able to say with certainty whether this was lobar or lobular ?

Sir Edward Marshall Hall. He has said it. Is that a proper question to his own witness in re-examination ? The gentleman has already said that it was lobar.

Mr. Vachell. I want to know.

Mr. Justice Lush. I think it is a fair question.—I have already expressed my opinion, that it was a lobar pneumonia. I must confess you cannot be absolutely certain without microscopical examination.

Mr. Vachell. I think you told us you made no such examination ?—That is so.

As to the condition of the heart, you have spoken to, you made no microscopical examination there ?—No.

And is it possible without microscopical examination to give anything like an exhaustive opinion on the condition of the heart ?—No, it might have been in the early stage of fatty degeneration without showing any signs.

The early stage of fatty degeneration you would want a microscope to detect ?—Yes.

You have spoken about one swab that you examined, which I think my friend Sir Edward accepts as being the swab taken from Leonard's throat ?

Sir Edward Marshall Hall. Said to be taken from Leonard's throat.

Mr. Vachell. Very well, said to be ; I do not want to pin you to anything. After three weeks from the first seizure by diphtheria, if the membrane has passed away, do you always find on bacteriological examination signs of this Klebs-Loeffler ?—The bacillus is often absent after three weeks.

In an undoubted case ?—In an undoubted case.

Of diphtheria ?—Yes.

Mr. Justice Lush. How soon after the throat is examined and found to be suspicious ought you to inject the antitoxin or, to put it in another way, is the injection of antitoxin effective if you allow, say, five or six days to elapse ?—The earlier it is given the more effective it is.

No doubt, but is there any date at which you could say it is too late, and that you have let the time go by ?—Yes, after five or six days it is of very slight efficacy.

Then if a child was suffering from diphtheria without showing obvious signs for, we will say, five or six days, although the doctor ought to have discovered the diphtheria at the end of five or six days, the discovery will not help you much, because it will be useless to inject antitoxin ?—As far as the question of antitoxin is concerned, but there are all sorts of general treatment which would be adopted.

But the antitoxin, at any rate, would be eliminated ?—Quite so, to a very large extent.

DR. RONALD BRIERS BERRY, *sworn.*

Examined by Mr. Micklethwait.

Are you the Medical Officer of Health for this City ?—Yes.

Are you also Superintendent of the Isolation Hospital at Over ?—Yes.

And as such do you see all the diphtheria patients that come in there ?—Yes.

Are you also the officer to whom notifications of diphtheria and, I suppose, other infectious diseases, are made ?—Yes.

With regard to diphtheria, is it a difficult disease to diagnose ?—In some cases no, in some cases yes.

Are there any signs which indicate the presence of it ?—Certainly.

Tell us, shortly, the usual indication of diphtheria ?—The first indication is a sore throat, and on examination of the throat you will find a patch of membrane there. In addition to that, you frequently get a discharge from the nose of a thick pussy character, sometimes tinged with blood. In many cases you get some enlargement of the glands at the angle of the jaw.

Mr. Justice Lush. In many cases ?—In some cases ; frequently ; not in all cases. In addition, there are certain general signs which are a sign of the poisoning which is taking place. These consist of pallor, frequently drowsiness, and very marked rapidity of the pulse.

Mr. Micklethwait. Is there any characteristic smell ?—Very frequently.

Is the smell a bad smell ?—Yes.

Is there anything peculiar about it, as regards diphtheria, as compared with anything else ?—Of course, I cannot describe the smell, except I would say in many cases it is characteristic. You get it in diphtheritic cases, and not in others. Skilled people can often tell whether a diphtheritic case is such almost by the smell alone.

Is it a smell of the breath ?—Yes, through the breath.

With regard to vomiting, is that a common indication of diphtheria at any stage ?—It is an indication at a later stage of a very serious import ; sometimes you get it in cases about the eighth or ninth day, and sometimes earlier, and then you look very seriously on such cases. It makes the prognosis very bad.

We have heard that the method of dealing with diphtheria is by the antitoxin treatment ?—Yes.

That is the ordinary regular method ?—Yes.

Do you agree with the last witness with regard to the length of time in which it ought to be done, five or six days ?—Yes ; I would not say I would not give it after that ; I should give it, but I should not hope to get very much benefit from it.

In the case where a careful doctor, after examining a patient, finds the symptoms present which you have mentioned, what is the proper course, in your opinion, for the doctor to take ?—If he thinks it is diphtheria his first step should be either to get the child rapidly removed to hospital, or to give antitoxin himself. If he is doubtful it is diphtheria, but has a very strong suspicion, then he should carry out the same steps, and take a swab as well. If his suspicion is not very strong, he should take a swab, and wait for the result of that before he takes any other steps.

Mr. Justice Lush. You say if it is a doubtful case, and there is nothing to indicate diphtheria, he should——?—He might take a swab, and wait for the result of that, but if there is the slightest suspicion I do not think he is justified in waiting.

Ought he to be suspicious of it. How ought he to be even more than suspicious if he sees the symptoms put to you, the drowsiness, the offensive breath, and the discharge with blood in it. Can you understand anyone not having his suspicions aroused by seeing all those symptoms ?—I think he should have diagnosed the condition, and more than suspected it if those symptoms were present.

Mr. Micklethwait. We know that this disease is extremely infectious ?—Yes.

I suppose the whole object of sending them to the hospital is to get them away from infection ?—That is one object ; the other is to give them satisfactory treatment.

Sir Edward Marshall Hall. Is it infectious, or contagious ?—Both.

Mr. Micklethwait. Did you receive a notification in the case of the little girl Nellie, who died ?—It was received in the office on the 11th.

Did you receive a notification in respect of Hilda ?—Yes.

And in respect of a little girl named Olive Cornock ?—Yes.

And also a little girl named Gladys ?—I did not receive the usual notification of an infectious disease in that case.

First of all with regard to Hilda, was she sent to your hospital ?—Yes.

Was she under your charge ?—Yes.

From what was she suffering ?—Diphtheria.

Mr. Justice Lush. That raises the same question again. Hilda was ?—Yes.

Have you had an opportunity of ascertaining whether, in your client's opinion, Hilda was suffering from diphtheria ?

Sir Edward Marshall Hall. I do not think he ever saw Hilda at all.

Mr. Vachell. The materiality as far as Hilda is concerned is on the question as to whether Nellie was suffering from diphtheria. Hilda comes from the same household.

Mr. Justice Lush. I do not overlook that, but when was that child sent into the hospital ?—August 11th.

Then at that time the investigation of the case against Dr. Hadwen was really proceeding.

Mr. Vachell. No, my Lord. She died on the Sunday.

Mr. Justice Lush. Early on the Sunday morning, and the suspicion at all events of neglect had already arisen, had not it, with regard to Dr. Hadwen ?

Sir Edward Marshall Hall. On the 11th Dr. Washbourn had received intimation of the necessity of a post-mortem examination.

Mr. Justice Lush. I did not want to put it higher than it should be put. All I am saying is it is a pity Dr. Hadwen had not an opportunity of satisfying himself about Hilda, but I did not know whether you wanted to proceed in detail with Hilda's case.

Mr. Vachell. I will say no more about Hilda, but now there is another child Dr. Hadwen did see whom we are going to ask about.

Mr. Micklethwait. Was the little girl, Gladys Burnham, brought to the hospital ?—Yes.

On which day ?—The 12th, the Tuesday.

What was she suffering from ?—She was in a very poor condition and she had a very nasty thick discharge from the nose with crusts of blood on the edges of the nose.

What was she suffering from ?—I formed the opinion she was suffering from the late stages of diphtheria.

Is she still in the hospital ?—No, she has been discharged.

Then was the little girl, Olive Cornock, brought to the hospital ?—Yes.

On what date ?—The 12th, I think.

What was she suffering from ?—Diphtheria.

Is she there now or has she been discharged ?—Discharged.

Cross-examined by Sir Edward Marshall Hall.

You are Medical Officer of Health for this city are you not ?—Yes.

Have you yourself had much personal practice in diphtheria ?—Yes.

Before you were officially appointed ?—Yes, and I have considered it since I came.

Do you practise privately as well as being medical officer ?—No.

It is a whole-time appointment ?—Yes.

In the case of the child Gladys I think Dr. Colquhoun saw her ?—Yes.

And he reported it as a condition that might be diphtheria ?—Yes.

And it did turn out to be the last stages, the later symptoms of an old diphtheria ?—Yes, a late stage of diphtheria.

Do you mean to suggest that drowsiness is only consistent with diphtheria in the case of a sore throat ?—No.

Taking the ordinary sore throat, if I might say so, the common sore throat which is not diphtheritic or anything of the kind, is not that one of the most lowering complaints you could suffer from ?—I do not look upon drowsiness as due to a lowering condition ; it is due to toxæmia.

Without toxæmia you get drowsiness ?—It is not classed as drowsiness.

Do you mean to say if you feel inclined to go to sleep in Court that is toxæmia ?—No, I attribute toxæmia to poisoning.

Have you ever had sore throat yourself ?—Yes.

Do not you feel drowsy ?—I do not think so, not with a throat of that kind.

It is not the sort of occasion you would choose to make a speech ?—No.

And it is a condition in which you would rather not talk to the people who come to see you ?—No.

Now let us deal with the offensive breath ?—There is a peculiar characteristic which you more or less expect.

If you have a peculiarly refined sense of smell, you can detect the offensive smell of diphtheria from the offensive smell generated by other sore throats ?—If you have sufficient experience.

Do you know Dr. Hadwen ?—No.

Never met him ?—No.

You know nothing of his practice or his qualifications at all ?—Very roughly.

You know he is a well-qualified man, do not you ?—Yes.

He has been 35 years in practice here, has he not ?—I take your word for that.

Do you suggest that the antitoxin treatment is always successful ?—No.

By no manner of means ?—It depends on the stage you get the disease.

Quite lately you have had a very bad instance of the failure of the antitoxin treatment, have you not ?—I do not want to give the name in open Court, but you might look at it if I write it down ?

Mr. JUSTICE LUSH. What is this name you are writing ?

Sir EDWARD MARSHALL HALL. I do not want to mention the name in open Court.

Mr. JUSTICE LUSH. What is the point of it then ?

Sir EDWARD MARSHALL HALL. I want to ask about this particular individual, we will call him A. B. to identify him. (To the Witness.) Do you know that particular case ? (Document handed to the Witness.)—Yes, I remember it now distinctly.

I want to particularly deal with this case. That was a case admitted on the 9th of August, 1924. There was a swab taken positive reaction, and it was admitted as a patient to the Over Isolation Hospital ?—I will take the dates from you.

Do you know that serum treatment was used for that child at all ?—Yes.

Mr. JUSTICE LUSH. Antitoxin ?—Yes.

Sir EDWARD MARSHALL HALL. On the 12th of September, that is a month and four days afterwards, was the child returned home as cured ?—Yes.

And five days afterwards, on the 17th, was the child found to be suffering from diphtheria, and also her brother ?—Yes.

And they were both brought back to the hospital ?—Yes.

And is the child still there ?—No.

But it was brought back again on the 17th of September, after it had been discharged as cured, and was kept in hospital up to quite recently ?—Yes, about three weeks.

So there is a very strong instance where antitoxin treatment at once failed ?—Not a bit.

Of course, that was done by the official authorities, and therefore, of course, there can be nothing wrong ?—No. The antitoxin cured the child, she became reinfected, and came back to the hospital.

Having had diphtheria, and being cured, she went back, and was reinfected with diphtheria within five days ; a very unlucky child ?—Very unlucky, and very unusual.

You heard the evidence of Dr. Washbourn, a gentleman for whom we all have the greatest respect ; you share it ?—Yes.

Would it be possible for you to say, upon the evidence that you have heard, what part pneumonia played in the death of this child ?

Mr. JUSTICE LUSH. Are you not content ; you have Dr. Washbourn's evidence.

Sir EDWARD MARSHALL HALL. I have also got it that he says the same thing.—As I stated before, I consider the pneumonia to be purely secondary to the diphtheria.

Did you say this : " It is not possible for me to say what part pneumonia played in this child's death " ?—There is also an addition, I think. I wish to qualify that.

You did say that. Then you certainly did add : " I regard the pneumonia as a sequela to diphtheria."—I cannot consider the pneumonia separate from the diphtheria ; that is the position I take up, that it is not a separate entity.

You cannot say whether she would have died of diphtheria minus pneumonia, or of pneumonia minus diphtheria ?—She died of diphtheria progressing through pneumonia to death. The thing is a natural progression, in my view.

Mr. JUSTICE LUSH. Without the pneumonia you cannot say that the child would have died ?—The pneumonia was part of the diphtheria.

Would you mind telling me, because I want to know if I am wrong, but I understood from Dr. Washbourn that without the pneumonia the child might never have died ?—I find it difficult to answer that question, because I consider the pneumonia as a development of the diphtheria.

That is really not the same thing as I was asking you ; I may have failed to put what I want.

Sir EDWARD MARSHALL HALL. If you are wrong in your diagnosis that the pneumonia was a sequela of the diphtheria, and if, in fact, the pneumonia was caused by the chill on the 7th, can you say that the diphtheria was the cause of death ?—No.

Mr. JUSTICE LUSH. That is what I meant ?—No, if you rule that out.

Re-examined by Mr. VACHELL.

Are you acquainted with the effect that antitoxin has had on the death-rate from diphtheria ?—Yes.

I do not know if you can give us the percentages, or whether I had better leave those for Sir William Willcox ?—I can only give them very roughly.

Sir EDWARD MARSHALL HALL. I thought you left it for Sir William. I did not touch it.

Mr. VACHELL. I will.

DR. EDWARD GRAHAM, *sworn.*

Sir EDWARD MARSHALL HALL. We have not had notice of this evidence.

Mr. MICKLETHWAIT. It is merely on this technical question about one of the swabs.

Mr. JUSTICE LUSH. Of course, I can allow it without notice.

Mr. MICKLETHWAIT. It is merely on this technical question about one of the swabs.

Sir EDWARD MARSHALL HALL. I do not raise any objection.

Mr. JUSTICE LUSH. I think I ought to allow it in any case.

Examined by Mr. MICKLETHWAIT.

What are your qualifications ? — Bachelor of Medicine and Bachelor of Surgery of Glasgow.

Did you attend a little girl, Hilda Burnham ?—Yes.

Was she taken ill while you were attending her ?—I was asked to see her. She was ill when I saw her, of course.

When did you first see her ?—On the 11th August.

And did you take a swab from her throat ?—Yes.

On what date ?—That date, on the 11th, the time I saw her.

And did you mark the swab ; did you mark the envelope, or whatever it was that was sent in ?—I simply put the full name and address, and sent it to the Medical Officer of Health.

Sir EDWARD MARSHALL HALL. The full name and address ?—Yes, her name and address.

Mr. MICKLETHWAIT. And you sent it to the Medical Officer of Health, Dr. Berry ?—Yes.

Cross-examined by Sir EDWARD MARSHALL HALL.

Did you put " Hilda Burnham " or " H. Burnham," or what ?—" Hilda," I think.

Then apparently that is not the one the doctor got because his was marked " Hilda Burnham," but never mind about that. Where was Hilda Burnham ill, at Mrs. Burnham's house ?—Yes.

And you were called in on the 11th ?—Yes.

Do you know that Dr. Ellis had been called in on the Saturday to attend to the other child ?—Yes.

And did you know that Dr. Hadwen had been previously attending the child before ?—They told me that when I arrived there.

So you were called in as a different doctor to Dr. Ellis. Had you ever attended them before ?—This girl I saw was a patient of mine.

Was she a panel patient of yours ?—Yes.

Was she in service then ?—She was about 18 years old. I think she was in service.

Does she live at home ?—I think so. She was ill at home, anyhow.

You are a very strong opponent of Dr. Hadwen, are you not ?—I do not think so.

Did you write that you would be ashamed to sit on any public body of which he was a member ?—Yes.

Sir Edward Marshall Hall. And you are chosen to give evidence with regard to another of these children.

Re-examined by Mr. Vachell.

Have you a club ?—No.

Are you the medical officer of some club ?—No.

How about Hilda ? How came you to attend her ?—She is a panel patient of mine.

How long had she been on your panel ?—I should say six months, or something like that.

SIR WILLIAM WILLCOX, *sworn.*

Examined by Mr. Vachell.

Are you a Knight Commander or Companion, is it, of the Order of the Indian Empire ?—Yes.

Companion of the Bath ?—Yes.

Companion of St. Michael and St. George ?—Yes.

Doctor of Medicine ?—Yes.

Fellow of the Royal College of Physicians ?—Yes.

Physician at St. Mary's Hospital, London ?—Yes.

Are you also an Assistant Physician to the London Fever Hospital ?—Yes.

At that hospital are there a large number of cases of diphtheria for attention ?—Yes.

And have you given considerable attention to that disease ?—Yes.

During the war were you Consulting Physician to the Army in Mesopotamia and the Dardanelles ?—Yes.

And there had you experience also of the treatment of this disease ?—Yes.

We are told that diphtheria is an infectious disease and contagious as well ?—Yes.

You agree with that ?—Quite.

What is the disease ; how does it originate ?—It is a disease caused by a microbe which was discovered in 1883 by Klebs and also by Loeffler, two independent scientists. It settles on a certain part of the body, often the throat or air-passages, and it grows there, and it produces an inflammation locally. Then there is the discharge which clots and a membrane forms which contains large numbers of this microbe and the microbes in the membrane produce a lot of powerful poison which is absorbed through the raw surface, and that causes the symptoms of the diphtheria, the general symptoms. So that the usual symptoms of diphtheria are headache and general pains, then there is the soreness of the throat where the membrane is, and the voice may be thick. Often the nose is affected, and if so, there is a discharge from the nose which is often slightly blood-stained, yellowish. The breath has a very offensive smell and the absorbed poison often causes drowsiness, great weakness, and vomiting. It is a powerful poison to the heart, and there is danger of death from heart failure during this disease.

Mr. Justice Lush. How soon does the vomiting come ?—There may be vomiting at the onset of the disease, and then it occurs later on when the disease becomes dangerous. It is a grave sign if it occurs after the first or second day, it means the powerful action of the poison on the vomiting centre in the brain. There is one other symptom I should mention, and that is that a not uncommon complication of severe cases is pneumonia.

Mr. Vachell. Before you pass away from the symptoms I should like you to tell us what the general appearance is of the membrane ?—It looks like dirty, yellowish-white wash-leather, but it is important to remember that you do not always get a large patch of membrane. Sometimes you may get little patches of exudation, little white patches comparatively small, but in a severe case you get a large patch of membrane.

Can the membrane become loose ?—Yes, it alters. It is a discharge from the body which, of course, changes. It changes in colour. It may become in severe cases black or it becomes dirtyish in colour and darker in colour, and then it separates off and leaves a raw surface.

Has diphtheria sometimes or at all times an effect upon the glands ?—Yes, the poison, assuming the throat is affected, is absorbed from the throat, and the little protective glands in the body, which are there for the purpose of filtering off poison which is absorbed, become enlarged, and you can feel them by carefully palpating or pressing the finger on them.

Is that something that is necessarily obvious without the palpation ?—No, in the very bad cases the glands are very enlarged, and in more than one case diphtheria has been mistaken for mumps, but in a moderately severe case there is some enlargement of the glands, but it might not be obvious to the naked eye. You would have to feel carefully to detect the enlargement.

What is the course that an ordinary prudent medical attendant should take if, when he is called in, he finds the patient suffering from some of these symptoms, the ones being thickness of utterance, sore throat, offensive breath, coloured discharge, and drowsiness ?—Coloured discharge from the nose ?

Yes, what do you say would be the proper and ordinary course for a reasonably careful medical man to take ?—After examining the patient and satisfying himself of the condition, a swab should certainly be taken, and if there is to his naked eye a reasonable suspicion that the case is diphtheria, that is if membrane or patches of exudation are visible in the throat, then it would be one's duty to give antitoxin there and then.

Without waiting for the result ?—Without waiting for the result of the bacteriological examination.

Mr. Justice Lush. Is that so common a treatment that you would say no reasonable or ordinary doctor would think of avoiding it, or is it only a treatment that most doctors would give ; I do not know how to better put the question I want to get answered ?—I would say it is the treatment which every doctor should give, that is, of course, unless it is too late for it to be given, and it is the treatment which is given in every case that goes to the Metropolitan Asylums Board hospitals and the other fever hospitals in London, assuming, of course, that there is a reasonable suspicion that the case is diphtheria, and if there is not, the bacteriological examination will tell you yes or no. One does not give the antitoxin as a rule after the sixth day, or it is not of so much value. One might give it in some cases, but it is not of such value after the sixth day.

Mr. Vachell. There was a point raised by Sir Edward Marshall Hall yesterday as to the effect of antitoxin treatment, and at my request he kindly left it for you to deal with, the suggestion being that the rate of mortality, I think, was higher before its introduction than since. Can you assist us there ?—The diphtheria antitoxin is one of the greatest discoveries of medicine, and it has reduced the mortality of diphtheria from 30 to 40 per cent., or even more.

Sir Edward Marshall Hall. Will you give us the figures on some official document for this ?—Yes, I have the Metropolitan Asylums Board report. It has reduced it down to 10 per cent. and under.

What is the date of that one ?—The 1911 Report of the Metropolitan Asylums Board.

I have 1923–24 ?—Yes, but 1923 has not got these curves in. I was asked to give it a long way back. I have 1923–24, but it has not got this curve. This is the curve. This is 1890 to 1893, before antitoxin. There the figure is 30 per cent., and it has dropped down since the introduction of antitoxin——

Mr. Justice Lush. To rather less than 10 per cent. ?—To rather less than 10 per cent. That is the latest curve that is given. I have the later report.

Does your own experience bear that out ?—Absolutely.

Mr. Vachell. Then there were the Registrar-General's returns referred to ; I think that is a different thing ?—Yes.

It was, indeed, on those figures that Sir Edward had something to say. What I want to know on that is the death-rate. What date is that ?—1923, page 35.

The death-rate from diphtheria, compared before 1893 and since, being about the date when antitoxin was first used ?—In 1895 it was first used in this country.

You have the figures there, have you ?—Yes. In 1893 the mortality from diphtheria was 389 per million in England and Wales.

Sir EDWARD MARSHALL HALL. What page are you reading from ?—Page 35.

Of the 1923 edition ?—Yes, and in 1923 it was 71 per million.

That is between one-fifth and one-sixth ?—That is so, it is under one-fifth of what it was.

Is that Table 6 ?—Yes.

Mr. JUSTICE LUSH. 389 against 71 ?

Sir EDWARD MARSHALL HALL. I have the 1924 book, the same table, and the figures are totally different. They are five years' figures, the figures I have got.

Mr. JUSTICE LUSH. Perhaps we had better wait.

Mr. VACHELL. You have heard all the evidence in this case, Sir William ?—Yes.

And, in addition to that, you read the Depositions, I think, before you came down to Gloucester ?—Yes.

You must, of course, for the purposes of an opinion assume that the facts are correct ?—Yes.

What do you say, in your judgment, was the cause of this child's death ?—Diphtheria and pneumonia.

First of all as to diphtheria, and the evidence that you have heard of the symptoms, do they all point to the child having suffered from diphtheria ?—Conclusively.

And strongly ?—I said conclusively.

Then arises a question on the pneumonia, the suggestion being that the pneumonia that the child suffered from was wholly independent ?

Sir EDWARD MARSHALL HALL. Not wholly independent.

Mr. VACHELL. Independent of the diphtheria. What conclusion do you come to upon that ?—I have no doubt but that the pneumonia was secondary to the diphtheria.

Now would you kindly give us your opinions ?—I have carefully listened to Dr. Washbourn's evidence as to his facts as to what he found at the post mortem, and he described it very clearly. Imagine that my fingers are tubes, and that they spread out in *that* way from the main tube *here*. He described that the whole of the bronchial tubes of the right lung were filled with diphtheritic membrane, some of which was adherent, and the opinion that he gave was that this membrane had formed in situ, and it had grown there, and it was that very part of the lung which was supplied by these infected bronchial tubes which was pneumonic, and, that being so, it appears clear to me that this pneumonia of the right lung was caused by the diphtheritic membrane, and poison in the bronchial tubes which supplied that identical part of the lung which was affected with pneumonia.

A point seems to have been raised about this pneumonia being unilateral, that, I suppose, means in one lung only ?—Yes.

What effect would that fact have upon your opinion ?—It would not have any effect in view of what was actually found. It is uncommon for this kind of pneumonia to be unilateral, but I have seen it occur in diphtheria.

Then comes the question of what sort of pneumonia it was ; lobar or lobular, and will you tell us what the symptoms of lobar pnuemonia are ?

Sir EDWARD MARSHALL HALL. Might he first say which he thinks it was ?

Mr. VACHELL. Yes, certainly ?—It is clear that in this case to the naked eye it was very difficult to say which it was, but in view of the condition of the bronchial tubes of the right lung I think that this was a massive, or very extensive bronchial pneumonia.

Sir EDWARD MARSHALL HALL. That is lobular ?—It is also called lobular.

Mr. JUSTICE LUSH. I wish you would reduce that to the terms of lobar and lobular ?—I do not like those terms myself very much. It should be lobular ; it is called lobular.

Mr. JUSTICE LUSH. It is only that we have worked in other terms of equation ?—I will restrict myself to that.

Mr. VACHELL. What, then, are the symptoms of lobular pneumonia ?—You mean the clinical symptoms, the symptoms during life ?

Yes.

Sir EDWARD MARSHALL HALL. Of lobar ?—Of lobar pneumonia the symptoms during life ? Its onset is very sudden, and the patient has what is called a rigor, or shivering fit, but in a child very often a convulsion occurs instead of the rigor, and the temperature will shoot up very high, often to 104, and there will be pains in the side, and cough ; the breathing is very rapid, and the child appears hot and flushed. It comes on very quickly, and it is a very dramatic change, the onset of lobar pneumonia.

Mr. JUSTICE LUSH. Would you tell me why it is called lobar, and why the other is called lobular ?—In most cases in lobar pneumonia you get the whole of one of the lungs involved, a large area, and in lobular pneumonia usually a little patch, perhaps the size of a marble, scattered through each lung, which you can see and feel by cutting the lung.

Is bronchial pneumonia always the subject of small patches ?—It is generally, but in some cases the small patches may be so numerous that they coalesce into one, and it is difficult to say whether it is lobar or lobular in certain cases.

Mr. VACHELL. Is vomiting a symptom of lobar pneumonia ?—No, it is not a common symptom ; in fact, it is not mentioned in the book which was referred to (Osler) as a symptom, but it is only fair for me to say that in children these symptoms are different from what they are in grown-up people, and although vomiting is not mentioned as a symptom, yet I have seen vomiting in children, and it may occur.

Mr. JUSTICE LUSH. In the case of lobar ?—Yes, it may occur, but it is not a common symptom, and if it does occur it would occur at the onset, within the first few hours.

Mr. VACHELL. Have you already mentioned whether vomiting is a symptom in diphtheria, and when it sets in ?—Yes, I have mentioned that. It may occur in the first day, or it may occur later on in the severe cases, and it is a dangerous symptom if it occurs late.

We have been told by Dr. Washbourn that on applying the floating test that the right lung was just awash. Does that assist you at all in coming to an opinion as to the nature of the pneumonia ?—It does to some extent. In lobar pneumonia, in the stage at which this is said to be, the lung would sink.

Mr. JUSTICE LUSH. After three days ?—I was rather going by the term Sir Edward used, red hepatisation. In red hepatisation it is the rule for the lung to sink. In lobular pneumonia the lung would usually float, or more commonly floats.

That is not a conclusive test ?—It is a rough test, but it is one which is always done in the post-mortem room. It is of value.

Mr. VACHELL. Can you express an opinion as to the probability of the child's going downstairs on the 7th of August having any effect upon her death, assisting in any way to her death ?—You mean as regards the pneumonia, do you ?

It would be in that way, if it was at all ?—In my opinion the going downstairs would not cause pneumonia such as was found in this case. Going downstairs, of course, would be harmful in this stage of diphtheria.

Mr. Justice Lush. Why would it not, in your opinion, cause such pneumonia as this ?—The lobar pneumonia is different in its appearance from this, in my judgment.

Then does it come to this : Have you assumed, or inferred, that this was lobular, and not lobar ?—Massive lobular.

Yes, one mass of infection. Then you do not think that the going downstairs could set up a chill which would account for that sort of infection ?—I do not, because one sees, or one has had described, the very cause of this pneumonia, the bronchial tubes all filled up with membrane.

Mr. Vachell. Is lobar pneumonia ever secondary to diphtheria ?—It is in rare cases, under 1 per cent. It is a complication of it.

Mr. Justice Lush. In practically 1 per cent ?—In less than 1 per cent. lobar pneumonia is a complication of diphtheria.

That is to say, practically one may almost eliminate the cases in which lobar pneumonia is a sequela of diphtheria ?—Bronchial pneumonia is very much more common than lobar pneumonia.

Mr. Vachell. For making a conclusive test as between lobar and lobular, is the microscope of assistance ?—Yes, the microscope is the only certain test where you have a condition such as was here, where you have such extensive lobular pneumonia as to involve the whole of the lung, the whole of the lobe.

Do I apprehend you aright when I say that the chief support of your opinion is the fact that there was found in the tube the actual diphtheria itself ?—Yes.

Going down into the vessels ?—Yes, that is one reason for my opinion. Another reason is the clinical history of the case. The pneumonia in this case appeared to come on insidiously.

Sir Edward Marshall Hall. Did it ?—I rather gathered that from what I heard. There was no dramatic sudden change, as would have been likely to have occurred if it had been lobar pneumonia.

Mr. Vachell. We have heard that Dr. Ellis used the exploring needle or a syringe, a few hours before the child's death.

Sir Edward Marshall Hall. Not a few hours, an hour.

Mr. Vachell. Very well. I do not quite know what the suggestion against Dr. Ellis was.

Sir Edward Marshall Hall. I do not make a suggestion, but you cannot eliminate it. It might have altered the position. It was a question of minutes.

Mr. Vachell. Would you give us your opinion as to whether Dr. Ellis did wrong ?

Sir Edward Marshall Hall. Is that anything to do with this case ?

Mr. Justice Lush. Have we really to trouble about that ?

Sir Edward Marshall Hall. No, my Lord, not at all.

Mr. Vachell. The comment my learned friend made when he got Dr. Ellis's answer left the impression on my mind, at any rate, that he was going to suggest that Dr. Ellis assisted in some way or other the child's death.

Mr. Justice Lush. I did not gather that.

Mr. Vachell. I should like to have it put at rest, at any rate What do you say ?—It was quite a proper thing to do because it is very difficult in children from the clinical examination to be certain whether there is solid lung or whether there is fluid there. Sometimes there is what is called empyema, that is a large collection of pus over the lung, and that is why it is proper to put a needle into the chest to make quite certain. The risk of doing so is infinitesimal if carefully done.

What opinion do you give as to the degree of care and attention that this case required by a medical man who was in charge of it ? You have told us about the swab.—Adequate care and attention were necessary to make the diagnosis and to take the necessary steps.

And in the course of the disease there were attendances, we know, on the 1st, 4th, 6th, and 9th. With what frequency should a case described as you have heard by the witnesses have been visited ?—A case like this should certainly have been visited daily ; it was a serious case.

Mr. Justice Lush. I do not want to put the question in an offensive form, but was it giving the child a fair prospect of recovery, assuming the symptoms there which you have spoken to, to only visit her on the 1st, 4th, and 6th ?—No, it was not.

Mr. Vachell. We heard that Dr. Hadwen prescribed hot water and vinegar gargle for one thing and a painting with glycerine with the aid of a feather. What do you say as to the value of those ?—Will you give them separately, please ?

Take the vinegar gargle first.—The vinegar and water would do no good ; I do not think it would do any harm.

Mr. Justice Lush. That is a satisfaction ; you cannot speak better of it than that.

Mr. Vachell. Then as to the glycerine painting ?—The glycerine, if pure glycerine, has slightly antiseptic properties. It might do a little good, but it would do no harm.

Mr. Justice Lush. Do good to what ?—To the throat.

To the diphtheritic patient ?—It would be useless for a diphtheria patient. I was assuming the treatment of the soreness of the throat.

I thought you were rather saying in a diphtheritic case ?—It would be useless in a diphtheritic case. The only treatment which is of any value is the antitoxin treatment and general hygienic nursing measures.

Mr. Vachell. Is the position of the patient in bed something to be attended to ?—Most important. There is danger of sudden death in diphtheria owing to the action of the poison on the heart muscle. Many a child has dropped back dead through sitting up in bed with diphtheria.

It is suggested that a quarter of an hour before death it is very improbable the child would have had sufficient vitality to have thrown off this piece of membrane ; what do you say as to that ?—I entirely disagree with that, because at the approach of death often convulsive movements occur.

Sir Edward Marshall Hall. There is no evidence of a convulsive movement here. Will you give him the words of the witnesses ?—Often vomiting occurs or the straining at vomiting as death approaches ; I have seen it many times.

Mr. Vachell. The examination of the throat, I suppose everybody knows, is generally aided by something to depress the tongue ?—Yes, unless that is done one cannot see the tonsils. The tonsils are down *here*. Unless the tongue is depressed all you see is the roof of the mouth.

What do you say to the use of the finger of an adult, the doctor himself, in the mouth of a child who was 10 years old. What do you say to that being used for depressing the tongue ?—I should say it was not a proper way of examining.

Mr. Justice Lush. Would it prevent the doctor properly examining ?—If the finger is put in the mouth—it depends, of course, on the size of the finger—it obstructs the view of the throat.

Sir Edward Marshall Hall. It depends also how much of the finger.

Mr. Vachell. I have no doubt.

Mr. Justice Lush. Ought the pulse to be taken ?—Yes.

And the temperature ?—Yes.

What do you say assuming it is true that neither was taken ; only on that assumption ?—One naturally takes the pulse ; it need not take five seconds to take it ; just a few seconds to feel the pulse.

Mr. Vachell. Should it be taken every time ?—The taking of the pulse need not occupy a long time, a few seconds.

Ought the temperature to be taken on each visit ?—It should be taken certainly at the first visit, and in the case of a doctor with a very busy practice one could hardly expect the temperature to be taken on every visit; it depends entirely on the condition of the patient on a particular day.

Mr. JUSTICE LUSH. Imagine a case of diphtheria when a child has not been seen for three days?—Yes, then it would be wise for the temperature to be taken; it should be taken.

You said a child has been known to fall dead from being in a wrong posture in bed?—From sitting up in bed.

If the child is suffering from a severe attack of diphtheria after seven days, eight days, indeed I think it is nine days, would not you expect going downstairs, walking with her bare feet on a tiled floor, drinking water, and coming up again, to produce a much more serious and rapid condition?—Not necessarily.

Sitting in a wrong posture may account for death. The thing this child did seemed such an extremely dangerous thing?—It was a dangerous thing, but it would not leave after-effects because with the heart in a condition of fatty degeneration it is liable to suddenly stop, and if it does not suddenly stop probably the danger has passed. It does not leave any progressive harm.

Mr. VACHELL. Could the fact of degeneration be discovered without the aid of a microscope?

Sir EDWARD MARSHALL HALL. After or before death?—In a case of this kind it would be necessary to have a microscope to discover it. You would not see it with the naked eye.

Mr. JUSTICE LUSH. What is that you would not see?—Fatty degeneration of the heart.

(Adjourned for a short time.)

Mr. JUSTICE LUSH. Mr. Vachell, I want you and Sir Edward to look, if you will, at that case you quoted, because as at present advised I shall act upon the ruling of the Court of Crown Cases Reserved.

Sir EDWARD MARSHALL HALL. 8 Queen's Bench Division.

Mr. JUSTICE LUSH. I thought you might like to know in case you have not seen it. You do not know of any case in which that has been commented on. It is a very important case.

Sir EDWARD MARSHALL HALL. No, I do not. I know of no authority questioning Mawbie.

Mr. JUSTICE LUSH. Neither do I.

Mr. VACHELL. (To the Witness.) I want you to consider the effect of the diphtheria on this child from this point of view. Supposing that this pneumonia, whether it is lobar or lobular, was independent in the first instance of the diphtheria, that she got it when she went downstairs that day. Would the fact that she was already suffering from diphtheria, and that diphtheria had been neglected in treatment by the doctor, in your opinion shorten or prejudice her chances of recovery?—Undoubtedly.

In what way?—The weakness and debilitating effect of the diphtheria would greatly diminish the resistance of the little girl to the pneumonia.

However caused?—However caused.

If the diphtheria had received adequate treatment would that have lessened the chance of her falling a victim to the pneumonia?—Very greatly.

Cross-examined by Sir EDWARD MARSHALL HALL.

Have you by any chance had a consultation with my learned friends during the adjournment?—No, I have not seen them.

I did not know whether that long question was what we call a question you wanted to be asked?—No, I have not seen them.

Not that there would have been anything irregular; it would have been perfectly proper. I see by the qualifications and the lists of distinctions my learned friend has read out that you have practically received every honour that you can practically receive short of a peerage, so you are a man of very high position and very skilled in your profession.

Mr. VACHELL. He has not answered that question.

Sir EDWARD MARSHALL HALL. When were you first called in by the Director of Public Prosecutions in this case?—A few days before—I can give you the exact date—the magisterial proceedings.

That was a day or two before the 2nd October?—If you will allow me, I will give you the exact date.

Very well, you shall?—On September 18th I received the depositions.

At that time the Coroner's depositions had been taken and their verdict returned, had it not?—Yes, they were sent to me.

And the magisterial depositions had not been taken?—No.

The magisterial hearing was in fact pending?—Yes.

And they did in fact come on on the 2nd October?—Yes.

May I take it that you are the official adviser to the Home Office?—Yes.

At the present time?—Yes.

And your private practice, I take it, is confined almost entirely to consulting practice, where you are called in by some other medical man as a rule?—Yes, that is so, and, of course, I spend a great deal of time at hospital work.

But you do not lay yourself out to see patients in the first instance without an invitation of a medical man?—No.

Have you had much personal experience in the early diagnosis of diphtheria, I mean before it has been already diagnosed by somebody else?—Yes, I have.

In the old days when I take it you were in practice, before you did your official work?—Yes, and in hospital practice one sees a lot of throat cases.

But you would see those after the house physician or surgeon had sent them?—They would come up to the out-patient department and they would be seen by me first.

You mean you would get people coming to you with early symptoms of diphtheria which had not been diagnosed by any independent medical man?—Yes.

Do you say that diphtheria is a less deadly disease now than it was?—Yes, it is much.

I was asked to let you have and I let you have during the interval this copy of the statistical review, the Registrar-General's report of 1924?—1923 it is.

I have 1924?—Excuse me, it is 1923. The date is 1923 and mine is the same one as yours. It is for the year 1923.

Page 35 is the one I am referring to. I am quite sure there must be some way of reconciling these figures, but I did not hear the figures you read out. Does the fifth column of that book purport to be the annual death-rates from the principal epidemic or general diseases from 1838 to 1923?—Yes.

Is it worked out in periods of five years?—Yes.

There are columns for every disease, small-pox, measles, scarlet fever, diphtheria, diphtheria and croup, whooping-cough, tuberculosis, tuberculosis of the respiratory system, and cancer?—Yes.

Incidentally I see the last one is appalling. Have you taken diphtheria and diphtheria with croup altogether as one?—Yes.

If you take diphtheria and diphtheria with croup you get a reduction; is that what you mean?—Yes.

In 1891 to 1895 the total of diphtheria of all ages was 576 per million; is that right?—I do not add them together, they are taken separately; I mean the diphtheria and croup includes the diphtheria, the preceding one. Croup is a particular type of diphtheria.

Do you mean to say the figure in the fifth column includes the figure in the fourth column?—Yes, it does; you will find it a little more than the one. If you look at the lowest line on the page for 1923 you will see that they are the same less 71. Croup is laryngeal diphtheria and in the old days it was called croup. Nowadays we call it laryngeal diphtheria.

Do you mean from that we are really to exclude the fourth column altogether?—The fifth column is the fourth column plus membranous croup.

Then what is the good of putting in the fourth column at all ?—Because in the old days before the diphtheria bacillus was discovered, the term membranous croup was used and that was really diphtheria and the Registrar-General in his returns includes membranous croup with the diphtheria, in order to give the total cases of diphtheria. I assure you that is so.

The figures I was dealing with, diphtheria as apart from diphtheria with croup, the figures for 1920, that is the last five years, are more than they were in 1871–1875, much more ; 121 and 142. Now take column 4 ?—If you will allow me I can explain that. The diphtheria bacillus was not discovered until after this time. It was discovered in 1883 and therefore before the diphtheria bacillus was discovered, it is obvious that cases that were notified as diphtheria were very much smaller. If you take the time since the diphtheria bacillus has been discovered, you will see there is a steady diminution and that is shown by all the figures given here.

When was the inoculation first practised ?—1895. Will you take the figures I read out ?

1895. What figure do you read out for that ? —The figure along that red line.

You have the single years ?—They are the single years and the quinquennial years show the same thing.

In 1895 it was 313 ?—And now it is 71.

But there are no returns for 1921–22 ?—Yes, I think so.

Will you just look at that. If you are right in saying that that column includes the preceding column, what do they mean by putting " ? ? " in 1921–22. Look at the bottom. I am not dealing with the years. It is the fifth column at the bottom. If your contention is that the fifth column includes the fourth column, why does the fourth column say 126 and the fifth column merely " ? " for 1921 ? They say " Deaths from diphtheria 126 ; deaths from diphtheria with croup none ? " and yet you say they are included. Look down at the bottom of the column where the deaths from diphtheria are shown as 126. Then you say diphtheria with croup includes diphtheria and is simply the addition ?—Yes.

But there they have put " ? ? " ?—Probably there were one or two doubtful cases.

Then they would have put down 126 in that column and they would put 107 in the next column ? —Apparently the Registrar-General was not certain from his figures what he should put there.

That is quite obvious, you see, and under the age of 15 in the collateral page they are the same thing. He does not include the previous figure ?— Which year is that ?

1921–22 ?—He puts the " ? " there. I do not know why he does that, but I can assure you, because I have had great experience of these figures, that the diphtheria and membranous croup are the diphtheria plus the cases that are notified as croup.

I will accept your explanation, but it is not very obvious to the casual observer of this book ?— Statistics are always puzzling.

I think they are intended to be puzzling. That is your evidence, that there is a steady reduction ?— A steady reduction, 500 per cent. in that year I gave.

Now here we have the annual report of the Metropolitan Asylums Board for 1923 and 1924 at page 86, Table 18 ?—I have the year before.

Look at Table 18 : " Summary of cases admitted with mistaken diagnoses during 1923 and deaths occurring amongst those cases." That deals with the Brook Hospital, Eastern Hospital, Great Northern Hospital, North-Western Hospital, North-Eastern Hospital, South-Western Hospital, and Western Hospital. Those are the main hospitals ?—Yes, and there is a total.

What is your total ?—2021.

There were 2021 wrong diagnoses of diphtheria admitted to those hospitals. Out of those, how many died in the London area ?—77.

And 2000 odd were admitted on a mistaken diagnosis ?

Mr. Justice Lush. I am afraid I do not quite understand it. What does it mean, that 2000 people were thought to have diphtheria when they had got something else ?

Sir Edward Marshall Hall. Yes, that is what I contend it means.

Mr. Justice Lush. What does it mean ? A mistaken diagnosis ?

Sir Edward Marshall Hall. " Summary of cases admitted with a mistaken diagnosis during 1922 and deaths occurring amongst those cases," and they give you diphtheria or membranous croup, so as to include anything, and I am told it is over 2000 and there were 70 deaths.

Mr. Justice Lush. Does this mean that 2000 people were thought to have diphtheria when they had not or thought not to have it when they had it, or both ?—It is this : These figures are for the London hospitals, and, as everyone knows, London is very overcrowded in the poorer districts, and those are the cases that are sent to the hospitals because the doctor is suspicious of diphtheria. He dare not wait for a swab to be taken, because if he did numbers of other children would become infected. He sends them to the hospital. It is hardly fair to say they are cases of mistaken diagnoses. They are cases of suspicious diagnoses, and a diagnosis is made at the hospital.

Mr. Justice Lush. You mean cases, many of them sent from over-caution ?—Cases of bad throat where diphtheria is suspected, and when the bacteriological examination is made it is found negative.

Sir Edward Marshall Hall. But the Registrar-General, who publishes the Report, describes them as mistaken diagnoses of diphtheria ?

Mr. Justice Lush. Yes, that is really what Sir William means.

Sir Edward Marshall Hall. In the next year the numbers were 1985, and 36 deaths out of those. That is to say, 1985 people were sent in as suffering from diphtheria, if you like, because some were only suspected, but of them 1985 were not suffering from diphtheria, and of those 36 died ?—If those mistakes were not made the amount of diphtheria in London would be greatly in excess of what it is. It is for the sake of the public health.

Mr. Justice Lush. Because doctors would keep people away who really had diphtheria ?—They would keep them, and they would infect others.

Sir Edward Marshall Hall. You know Sir George Newman ?—Yes.

His Report is of great value ?—I have worked with him.

I have the Report here on the state of the public health for the year 1921, and this is from Sir George Newman's Report on this matter at page 55 : " It seems likely that part, at any rate, of the increase has been attributable to the notification of diphtheria in cases of mild illness occurring among contacts in institutions or homes." Then it goes on : " Apart from the fact of contact, or the receipt of a positive report on the examination of throat swabs, notified cases in addition have sometimes found persons not suffering from illness at all, but who, on the strength of the examination of the swab, have been diagnosed as diphtheria carriers " ?—Perfectly true. Sir George Newman is trying to explain away the frequency of occurrence of diphtheria, and, as he points out, some people are over-cautious. They notify diphtheria because there is bacillus in the throat, but no illness. That is not diphtheria. Diphtheria is the illness of diphtheria, plus the Klebs-Loeffler bacillus, and the figures given for diphtheria, as Sir George Newman says, may be a little high, because some doctors are over-cautious, and have notified cases where there has only been a bacillus in the throat, and no illness. Others, on the other hand, have notified cases of people who have been in contact with diphtheria, and have, perhaps, got influenza.

Why should not that same argument apply to the Registrar-General's Return ; why should it not include in the death-rate of diphtheria cases, diphtheria cases which are not diphtheria cases at all ?—He would include them if the death certificates said diphtheria, because he is guided entirely by the certificates he gets. He knows nothing about the cases.

Do not you think those figures, especially the mistaken diagnoses of 2000 in one year, and practically 2000 in the next year, and a remark like that of Sir George Newman's in the public health volume, are very likely to affect the mind of a man who is practising in a local town, and who is most strongly prejudiced against any form of inoculation ?—I do not think they should. I think one should read the statistics, and take a commonsense view of them ; they are perfectly explicable and one can understand them.

When you were called in you had the material at your disposal you have told us of. When did you first meet Dr. Washbourn ?—On the night before the hearing at the Magistrates' Court.

You have read, of course, the Coroner's depositions. You probably heard Dr. Washbourn give his evidence before the magistrates ?—Yes, I did.

Did you notice that whereas before the Coroner he was positive as to two things, that it was lobar pneumonia, and that the heart was normal, before the Magistrates he weakened on both these points, and said he might be mistaken as to whether it was lobar or lobular, and he agreed that it was difficult to diagnose the condition of the heart without a microscopical examination ; you noticed that ?—I did not notice it. I read Dr. Washbourn's evidence before the Coroner's Court, and I think it was identical with what he gave before the Magistrates' Court.

Do you ?—In the cross-examination and re-examination, I think in the Coroner's Court, I believe Dr. Washbourn explained fully his views about the pneumonia.

Do you agree with this ? I am reading now from the evidence given by Dr. Washbourn this morning in this Court, and you heard it : " The child may have contracted a chill by going downstairs on the 7th of August, which chill might have developed into pneumonia." Do you agree with that, yes or no ; it is quite simple ?—I agree with that in the abstract.

What about the concrete ?—I do not think this pneumonia was due to chill.

He is dealing with the pneumonia that he found ?—Yes, that is what I mean.

He is dealing with the pneumonia he found, and which he has admitted in Court this morning was lobar pneumonia of two or three days duration, and he says the child may have contracted a chill by going downstairs on the 7th of August, which chill might have developed into pneumonia ; that is that pneumonia. Do you agree with that ?—No, I do not.

Then he said, " I think the child had the pneumonia which I should expect to find following a chill " ; do you agree with that ?—No.

Do you agree with this : " The pneumonia I found was consistent with having been contracted two or three days before death " ?—That might have been so.

" The pneumonia I found is the kind I expect to find when a child has contracted a sudden chill " ; do you agree with that ?—No, I do not.

" The pneumonia was enough by itself to cause death. It might have resulted from a chill, which might have been contracted when the child walked downstairs " ; do you agree with that ?—There are several questions involved in that.

I am now reading from what he said before the Coroner, of which you were furnished with a copy ?—In that statement there are three or four questions.

" The pneumonia was enough by itself to cause death " ; do you agree with that ?—Yes.

" It might have resulted from a chill, which might have been contracted when the child walked downstairs " ?—No, I do not agree with that.

Before the Coroner he gave the same answer : " The pneumonia I found is the kind I expect to find when a child has contracted a sudden chill " ?—I do not agree with that.

It is only fair to Dr. Washbourn to read one thing else he said : " I do not think the chill was the cause of the pneumonia, because of the presence of adherent membrane in the bronchial tubes. It is a reasonable apprehension that diphtheria might result in pneumonia. It is not possible to say for certain whether the child died from pneumonia, or not," and it was upon that that Mr. Clements put the question, and got this answer : " The pneumonia I found is the kind I expect to find when a child has contracted a sudden chill," and then, in answer to Mr. Haddock, who was representing the relatives : " It is not the usual form of pneumonia to follow diphtheria." Those are express opinions of Dr. Washbourn, and I am afraid you do not agree with them ?—I am sorry, but I only give you my opinion from experience.

Did you point out to the Treasury officials that you did not agree with Dr. Washbourn's evidence ?—I sent a report on the case which expresses what I have already said in examination-in-chief.

I put it to you, do not you know that before the Magistrates Dr. Washbourn, who had been definite upon the subject of its being lobar pneumonia, was a little doubtful as to whether it might not have been lobular. Did not you find that. You were there when he gave his evidence ?—Yes, I was.

He contradicted himself before the Magistrates. He said, " I cannot say if the child would have died if she had not contracted pneumonia." Before the Magistrates he said, " It is impossible for me to say what part the pneumonia played in the child's death. I think the child had the pneumonia which I should expect to find following a chill. There is a possibility of the child having lobular pneumonia, but I cannot say for certain." Then he qualified that, " The pneumonia I found is the kind I expect to find when a child has contracted a sudden chill. I found no membrane in the throat." So there is a really serious difference of opinion between you and Dr. Washbourn ?—Yes, I do not agree with you that there was a difference of opinion between what Dr. Washbourn said at the Magistrates' Court and what he said at the Coroner's Court, if this is correct.

He got as far as this before the Magistrates, that he gave this answer which I have just read out, " There is a possibility of the child having lobular pneumonia, but I cannot say for certain."

Mr. Justice Lush. If Sir William Willcox is right, as I understand, he does agree that pneumonia may have been the cause of this child's death, it seems to me to follow that the one critical question on this part of the case is whether the pneumonia may reasonably have been caused by a chill or whether the only reasonable view is that it was a sequela of the diphtheria.

Sir Edward Marshall Hall. Then my learned friends are in this serious difficulty, which once arose before the late Mr. Justice Field in a case in which I was engaged years ago, where there were two medical men of great position and one said it was possible that death might have resulted from a certain cause, and the other said he did not think it was possible. Upon that, Mr. Justice Field ruled that there was no case to go to the Jury because it was the duty of the prosecution to prove affirmatively beyond any reasonable doubt that their case was right.

Mr. Justice Lush. I do not see how I can withdraw the case from the Jury.

Sir Edward Marshall Hall. I am not asking your Lordship to, but I am only putting to your Lordship the dilemma in which my friend is. Upon the evidence given by Dr. Washbourn before the Coroner as the result of his post-mortem examination, assuming it to be accurate, there was no fatty degeneration of the heart. Assuming Dr. Washbourn's evidence to be correct there was no fatty degeneration of the heart, there was unilateral pneumonia and lobar pneumonia ?—A pneumonia which in his opinion was lobar.

I say, assuming his evidence is correct, and further a pneumonia of the kind which he would expect to follow a chill. That was the evidence of Dr. Washbourn ?—It was, but he amplifies that.

Give me anything which was said before the Coroner ?—Page 27 ; that was before the Coroner. It was by Mr. Clements, " The pneumonia was enough by itself to cause death. It might have resulted from a chill which might have been contracted when the child walked downstairs. I do not think it was the cause of the pneumonia, because of the presence of adherent membrane in the bronchial tubes. It is a reasonable apprehension that diphtheria might result in pneumonia."

I have read all that. Go on " I did not examine the loose piece. It is not possible to say for certain whether the child died from pneumonia or not," and then the important part I called your attention to is later on. " The pneumonia I found is the kind I expect to find when a child has contracted a sudden chill. It is not the usual form to follow diphtheria." That was all at the inquest ?—He says that, but you have missed out the paragraph between those two.

That is his re-examination ?—Before he said that.

" Croupous pneumonia is not, in my opinion, accompanied by such a membrane as found in the bronchial tubes of the right lung." What is that? That is lobar pneumonia ?—That is lobar pneumonia. He says " The membrane I saw was of the typical wash-leather appearance " which Dr. Washbourn describes as typical of diphtheria. He says " The membrane found in the smallest bronchial tubes in a case of croupous membrane is entirely different from that found in diphtheria."

Sir EDWARD MARSHALL HALL. In spite of that he goes on to say " The pneumonia I found is the kind I expect to find when a child has contracted a sudden chill. It is not the usual form to follow diphtheria." Then the Jury asked him a question and he said, " Personally I do not think the child developed pneumonia by the walk downstairs, but she might have done." Dr. Ellis said exactly the same. " Nevertheless, it may have begun." You see when he was re-examined before the Magistrates he said this " In this case I found signs of diphtheria in the bronchial tubes and those signs were sufficient to cause extensive lobular pneumonia." That is what I meant ; he rather weakened on the question. He goes on, " I formed the opinion it was lobar pneumonia, but I am not sure the opinion I formed was correct."

Mr. VACHELL. Would you mind reading a little further ?

Sir EDWARD MARSHALL HALL. " Sufficient to cause extensive lobular pneumonia. I have formed the opinion it was lobar pneumonia, but I am not sure that that opinion was correct."—I do not like to express an opinion on my colleague's evidence.

Before he gave his evidence before the Magistrates, and after he had given his evidence before the Coroner, of course he had heard your weighty opinion on the subject ?—Probably.

And put in that most forcible way in which you can put an opinion ?—No.

You have had a great deal of experience in delivering lectures to students, have you not, and very successfully ?

Mr. JUSTICE LUSH. Do you recognise yourself in that description ?—I think Dr. Washbourn is senior to me. It is more likely he would have lectured to me than I to him.

Sir EDWARD MARSHALL HALL. I am not questioning your opinion. You have not a shadow of a doubt in your mind that this child died of diphtheria ?—No.

You are certain if you had been called in you would instantly have advised either an inoculation and a swab, or probably both ?—Yes, and I should have had the child removed to the Fever Hospital.

And in your opinion the cause of death was pneumonia which was consequent on diphtheria, and therefore the real cause of death was the two things together ?—Yes, I am clear about that.

You formed all these opinions upon the evidence of Mrs Burnham and the other people called as to the state of the child ?—Yes.

Did you happen to read the evidence which Dr. Hadwen had given at the inquest ?—Certainly, I read it with great care.

If his evidence is true he did not diagnose this as diphtheria ?—No. Dr. Hadwen stated that he regarded the case as an ulcerated throat, a follicular throat.

I do not think he used that term, but ulcerated tonsillitis. In order to come to the opinion you have expressed must you disregard Dr. Hadwen's evidence entirely ?—I do not disregard it.

Does anything in Dr. Hadwen's evidence help you to the opinion that he had in fact diagnosed diphtheria ?—I cannot imagine that Dr. Hadwen had diagnosed diphtheria, because if he had I am quite sure he would have taken proper steps.

That is the sort of answer I expected from a man in your position. Therefore you will as a medical man admit—we are dealing with probabilities—that in all human probability what Dr. Hadwen did, if this was a case of diphtheria, was that he failed to diagnose it as such ?—Yes.

Mr. JUSTICE LUSH. That is Sir William Willcox's view.

Sir EDWARD MARSHALL HALL. Quite. One of the symptoms of the ulcerated throat is a soreness of the throat itself, is it not ?—Yes.

That is to say, a soreness which is very evident on any attempt to swallow ?—Yes.

In diphtheria, on the other hand, that soreness is not necessarily present ?—In diphtheria often the pain is less.

If, in fact, there was a soreness of the throat in that common colloquial sense, that would be one possible symptom that might militate against a diphtheria diagnosis ?—No, I would not say that.

You will not go so far as that ?—No. It is perfectly true that often the most painful throats are not diphtheritic. If a throat is excessively painful it is very probable it is a quinsy, or some other form of tonsillitis, but with diphtheria there is a sore-throat, the throat is painful.

Dr. Hadwen is admittedly a very busy medical man, you have seen his qualifications ?—They are very good qualifications.

He is known as a man with peculiar views on any form of inoculation, is he not ?—I do not know ; I have not read his works.

Do you know he is an antivaccinationist ?—Yes, I do know that.

Just test, in your opinion, the view. Supposing a man who is moving about in the midst of an epidemic of small-pox as a doctor, coming in close contact with the cases, and supposing he never is vaccinated himself, would not that give you a strong indication as to whether his belief in non-vaccination was honest or not ?—Yes. Possibly he may have been vaccinated in earlier life.

He could have no control over that because they do it so young, you know, but I am going presently to call him, and I am going to ask the Jury to believe that he never has been vaccinated at any stage of his existence. Do not you think yourself that a medical man going about in the midst of an epidemic of small-pox, who persistently declines to be vaccinated, must have an honest belief in what he thinks with regard to vaccination ?—I should think that is evidence of such.

There is, is there not, even amongst the highest members of medical profession at the moment, some difference of opinion with regard to inoculation of serums or vaccines ?—Are you speaking of all kinds ?

Generally, first of all, there is a difference of opinion ?—Yes, there is.

There are men of the highest possible class who will not allow their patients to be inoculated at all ?—That is with vaccines.

Vaccines, of course, are prepared from the human body itself ?—They are prepared from growing germs and killing them and mixing them with the blood.

The serum is prepared by culture from an animal ?—Serum is from the blood of an animal.

There is a distinction, but there is a very strong feeling amongst very many members of the medical profession, and of the public, against any inoculation by vaccines ?—Yes, by vaccines.

Mr. JUSTICE LUSH. I am afraid I do not know enough to understand that. Is this antitoxin you use for diphtheria a vaccine ?—No, it is a serum.

How is it made ?—It is made by inoculating a horse with diphtheria toxin, the poison of diphtheria, and by so doing the horse develops protection, immunity in its blood, and then after the horse has been protected by several doses of the poison the horse's blood is taken and the serum separates, a straw-coloured clear liquid, and it is that serum which is the antitoxin, and it is that which is injected into the patient suffering from diphtheria. As regards the use of that antitoxin, I do not think there is any difference of opinion as to its advisability and efficacy if given.

Without going at length into it, what is a vaccine as distinguished from that ?—A vaccine is this: You get a certain microbe, say a typhoid bacillus ; that is grown and then millions of these microbes are taken in a saline, that is salt and water, and they are destroyed by heat, and that solution of the microbes is injected into the body.

Sir EDWARD MARSHALL HALL. That is to say, the dead microbes injected to give the living microbes something to do ?—The dead microbes react on the body and cause the body to produce protective substances.

Is the substance that is used for small-pox vaccination a vaccine or a serum ?—That is rather difficult to say. That is really a serous liquid obtained from the calf, and that is inoculated into the skin.

Is it a vaccine or serum ?—It is really a serum.

It is practically procured from cow-pox, is it not ?—Yes, that is right, but it acts in a different way from the diphtheria antitoxin, the small-pox or vaccine. When a person is vaccinated it produces a local reaction ; it produces a disease called vaccinia, and this illness caused by the inoculation protects against small-pox.

I am not going into the small-pox question, but we know that the House of Commons repealed the compulsory orders to the extent they did, and that was in consequence of great pressure of public opinion, but whether you and I agree or not we cannot express our private opinion ; at least you can, I cannot. If it is a fact that Dr. Hadwen has never in the whole course of his practice administered an antitoxin injection would you say it was negligent on his part not to administer it in this case ?—Yes, I would, or not to give some competent person the opportunity of administering it. I ought to qualify that answer of course. I am assuming that Dr. Hadwen had exercised sufficient skill to diagnose diphtheria.

Yes, I am assuming that. I need not put it quite as high as that. I can put it in this way : Assuming the conditions were such that Dr. Hadwen ought to have been suspicious that it was diphtheria—I am not dealing with a swab—do you say that having regard to the fact, if it is a fact, that he has never administered an antitoxin injection in his life, that he would be guilty of negligence if he did not either inject antitoxin in this case or call in some other doctor to do it ?—Yes, I think if he had not given the antitoxin himself that he should have sent the child to the Fever Hospital where it could have had the treatment.

Mr. JUSTICE LUSH. That does lead one to a difficulty we shall have to face ultimately. Supposing the opinion of a doctor is dead against antitoxin which the majority of doctors approve of, do you say that that necessarily connotes negligence on his part, although he may have been successful in curing patients who suffered from diphtheria without using antitoxin ?—I think in the case of diphtheria that it is one's duty to give antitoxin.

That I do not feel any difficulty in following, but it does not follow, although it is a duty in your opinion, that he is guilty of gross neglect if he honestly does not believe in it, and thinks he can cure without it, does it ?—I think if one reads the medical literature the evidence is so strong as regards the beneficial effect of antitoxin that I think it is one's bounden duty to give antitoxin.

You say the evidence is so overwhelmingly in favour of its utility of cure that a man who will not use it is responsible ?—I think so.

Of a neglectful character ?—Yes, if he sees the case sufficiently early.

Sir EDWARD MARSHALL HALL. Therefore it comes to this, does not it, that any doctor, duly qualified though he may be, who honestly believes that any form of inoculation by vaccine or serum is harmful to the patient must give up practising in any case in which there is the necessity of administering antitoxin ?—My answer only applies to diphtheria. There are many sera and many vaccines about which evidence is not decided enough, and in such cases everyone is entitled to his own opinion.

Do you agree, or disagree, that there is a percentage of the medical profession in this country who do not believe even in diphtheritic antitoxin ?

Mr. JUSTICE LUSH. Even for diphtheria, is that so ?—I have not heard of them. I have heard that Dr. Hadwen does not, and there may be others, but I am not aware of them.

Sir EDWARD MARSHALL HALL. Would you say that Dr. Hadwen is, in your opinion, or in your view, the only man in the medical profession who is opposed to the use of diphtheritic antitoxin ?—I cannot recall any other. I know of no other ; there may be others.

Mr. JUSTICE LUSH. What do you think about a doctor's duty if he does go counter to the views of the vast majority of physicians in this matter. Is it his duty to tell the patient : "Now there is a treatment which most doctors follow, but I do not use it ; will you let me treat your child or not ?"—I think that would be so.

Sir EDWARD MARSHALL HALL. That is the view you would take of his duty ?—Yes.

Would you go so far as to say, in the case of a man who does not believe in it, it was wilful neglect of his duty not to do it ?—I am afraid I must say so, because it may mean the death of the patient.

Holding the view you do ?—Holding the view I do.

You hold the view, do not you, that abstention from vaccines is almost criminal, talking about small-pox vaccination ?—I do not like to use the word "criminal."

As near as makes no difference ?—It is very wrong.

And anybody who disagrees with that is, in your opinion, of course, misguided ?—Yes.

That is your strong, honest opinion, and with most people it would have great weight. Let us take another serum for a moment. Some years ago it was quite common, in cases of pneumonia, to inoculate with anti-pneumococcic serum ?—Yes.

That has now, except in Paris and Naples, been abandoned, has it not ?—It has, to a great extent.

Perhaps it is only fair to ask you this : Abandoned because you gentlemen in the profession have not yet satisfied yourselves that you have the proper serum ? —That is right.

You never abandoned the principle, but you think the serum that had been used was not sufficiently efficacious for the purpose ?—Yes, and that applies to many others.

I do not want to go into details, but there are many other sera which have, in the past, been injected with the belief that they were efficient, and have they now had to be abandoned by the medical profession ? —Yes.

I am not quarrelling with your opinion at all. You hold the opinion, and as you told us practically the whole of the medical profession hold the opinion, that the injection of an antitoxin in diphtheria is almost a specific if it is done quick enough ?—It is one of the most valuable things in medicine.

That will not relieve my Lord and the Jury of a question which they will have to decide hereafter, whether, in an honest bona fide belief that that remedy is not efficacious, a man who abstains from using it is guilty of wilful neglect ?

Mr. JUSTICE LUSH. Of course, you are faced with this difficulty, that an honest bona fide belief in some remedy, without calling in a doctor at all, does not justify the person who follows it allowing his child, for instance, not to have the treatment.

Sir EDWARD MARSHALL HALL. There is always the question: Has there been wilful neglect? That is the case of Mawbie.

Mr. JUSTICE LUSH. That means an intentional neglect; not the desire to injure the patient.

Sir EDWARD MARSHALL HALL. No, a deliberate neglect.

Mr. JUSTICE LUSH. Therefore the Court has held that an honest belief that there is no efficacy in the treatment does not excuse wilful neglect.

Sir EDWARD MARSHALL HALL. It does not exonerate a person who wilfully refuses to call in a doctor from the responsibility for the death of that child.

Mr. JUSTICE LUSH. The Legislature has compelled a parent to call in a doctor.

Sir EDWARD MARSHALL HALL. But no legislature has yet compelled a doctor to inoculate with an antitoxin serum.

Mr. JUSTICE LUSH. That is true, but the difficulty remains which I have pointed out.

Sir EDWARD MARSHALL HALL. I have got far beyond the initial and important point in this case: Did he diagnose diphtheria?

Mr. JUSTICE LUSH. That still remains.

Sir EDWARD MARSHALL HALL. I am only dealing with Sir William Willcox upon that hypothesis. (To the Witness.) Now as to the diagnosis of diphtheria in its early stages. Do you agree that the most important thing is the presence of patches?—Of patches of membrane.

Do you find patches even in tonsillitis?—Yes.

Do you know French's Index of Differential Diagnoses?—Yes, I know those diagrams.

Upon the diagrams which are exhibited in the book, do you agree that the diagnosis between follicular tonsillitis and diphtheria may be very difficult?—It may be impossible, unless a swab is taken, and that is the important thing, to take a swab.

It may be so difficult as to be impossible unless a swab is taken of it?—That is right.

There is a real danger in inoculation of antitoxin; there is a thing called anaphylaxis?—There may be a danger if the patient has been inoculated before with serum.

Or there may be a danger if the child is inoculated after?—You mean with the same?

The same serum?—Do you mean at the same time as its illness?

No, later on, a different illness altogether?—Yes, a person may be susceptible to serum if he has had one or more doses some time before.

Super-susceptible?—Yes, but I have never seen any fatal case from the use of serum.

The difficulty is this: Dr. Washbourn said, and I think you said, that on suspicion of diphtheria it is advisable to inoculate at once?—Yes.

My point is this: It is said it does no harm, but if, in point of fact, the patient had not diphtheria when that inoculation took place, if on a subsequent occasion it had diphtheria, and it was necessary to inoculate, there is an increased danger of what you call anaphylaxis?—It can be avoided if a person has had serum before; one gives the second lot of serum with special precautions.

If you do not know the patient has had a previous injection, then, of course, you cannot take the precaution?—If you do not know there might be some risk. I have never seen any danger from the use of diphtheria antitoxin thousands and thousands of times.

Let me try and summarise what the position is. On Dr. Washbourn's evidence there are two things which are against your theory with which you do not disagree, the condition of the heart, and the exact nature of the pneumonia. You, unfortunately, disagree?—I do not think we disagree about the condition of the heart.

In the case of the alleged diphtheritic membrane that Dr. Washbourn found, do you agree, or do you not agree, that it is impossible to say affirmatively whether that membrane was diphtheritic without a microscopical examination?—No, I do not. I think one can say that it is a diphtheritic membrane from its naked-eye appearance. I think Dr. Washbourn said that.

He did say that. What Dr. Washbourn said in fact was this: "I did not want a microscopic examination, although a microscopic examination would have been conclusive, because by the appearance I was able from my trained eye to say it was diphtheritic." You agree, do not you?—Yes.

Therefore, in that case, which is in favour of the theory of the prosecution, you agree to dispense with a microscopic examination?—Yes.

Let us take two points which are in favour of the theory of the defence. The first is the normality of the heart?—Yes.

The answer to that by you is, "No, I cannot accept that," because unless there is a microscopic examination you cannot say whether the heart was normal or not?—Yes.

So there being no microscopic examination of a symptom which would be favourable to Dr. Hadwen, you insist upon a microscopic examination as a test of diagnosis?—In a case of diphtheria like this, which became severe, I am quite certain there was some degeneration of the heart which would be found under the microscope, but you would not be able, I say, to tell that with the naked eye.

I suggest to you that you can tell?—You can tell with the naked eye if there is fatty degeneration in cases where the patient has been ill some time, say two or three weeks or more, because you can see the fatty appearance of the heart muscle, but in a great many cases it is not possible to tell with the naked eye and you have to make a microscopical examination.

I suggest to you a gentleman of Dr. Washbourn's position and integrity would never have reported that the heart was healthy—which were the exact words in his report—if he had had the slightest doubt upon it that could have been set at rest by a microscopical examination?—I do not agree with that. I think that expression "The heart healthy or normal" meant to the naked eye, and I have no doubt it did appear normal.

Surely it is a well-known thing, is it not, that one of the grave dangers of diphtheria is this affection of the heart?—Yes.

So grave that children are kept in an absolutely recumbent position and people are not allowed to come suddenly into the room. There must be no sudden noise, nothing of that kind, for fear the heart may fail upon sudden shock. Is not that so?—Yes.

And in conditions of diphtheria that is the grave risk, is it not?—Yes.

And if the patient who has got that diphtheria and is in that condition died, in all probability you would find a condition of heart which was consistent with that condition?—You would with the microscope, but you probably would not with the naked eye.

Do you mean to say that with a man of Dr. Washbourn's experience with the question whether this was diphtheria or not, if he had seen any doubtful signs in the heart he would not have instantly examined it with the microscope, because he knew that the question of the condition of the heart was important as affecting the diagnosis of diphtheria?—One does not have time to make these exhaustive examinations in many cases.

One does not have time to make microscopical examination at a post mortem even when the charge involves a charge of manslaughter or criminal negligence against a brother practitioner?—I did not mean that the examination should be made with lack of care, but in this case Dr. Washbourn had made a complete and exhaustive examination and had found the cause of death, and he did not think it necessary.

Mr. VACHELL. I am sure my friend will forgive me, but what Dr. Washbourn said before the Coroner was this, "The heart was apparently healthy; its cavities were not unduly distended."

Sir EDWARD MARSHALL HALL. I read it out to Dr. Washbourn this morning and asked him whether he accepted it. I read out the actual report he made and sent to the Coroner, and I read these words "Heart healthy, cavities not unduly dilated," and he accepted that as what he found and it was upon that I was asking. I will not pursue that part any more. Now as to the question of the lung. In the case of lobar pneumonia, what does the lung do, float or sink?—When the stage of red hepatisation is reached the lung sinks.

What do you call this but sinking? He said it sank and he qualified it by saying in re-examination it was just awash, that is to say, there was a little bit of water coming over the upper part?—He said it just floated.

His words were "Just awash"?—He said "Floated" before the Magistrates and "Just floated" to-day.

My learned friend put the word awash to him and he accepted it?—Yes, it only just floated.

I suggest to you the difference between lobular and lobar is apparent to the naked eye?—It is in some cases, not all.

Do not the lobules always have some healthy tissue round them?—They do in a case in which it is not very extensive. In this case it was exceedingly extensive, the lobular pneumonia.

If, in point of fact, the heart was right and this was lobar pneumonia, they are both unexpected sequelæ of death from diphtheria, are not they? Yes.

As to the question of this needle business before the child died, I do not think my learned friend followed what my point was?—With regard to the last answer, assuming the heart was right, but I disagree; I say the heart must have had some degeneration of its muscle.

I am assuming that the doctor's report is right, that the heart was normal and that the pneumonia was lobar. They are both against your theory of diphtheria sequelæ. You said they were a moment ago. If you want to qualify it, you may.—I have already said that lobar pneumonia is rare in diphtheria, and about the heart I have already said that the heart may appear apparently normal to the naked eye but yet have degeneration.

Those were not the questions I asked you. I said if Dr. Washbourn is right in his two statements that he heart was normal and that the pneumonia was lobar, they are unexpected sequelæ of diphtheria? —Yes.

Can you conceive of a case where it was more important that the person, against whom the possibility of a charge being preferred was at the moment obvious, should have been invited to be present at that post-mortem examination in common fairness? —The invitation to be present at a post-mortem examination rests entirely with the Coroner and I would prefer not to criticise any action a gentleman of that position takes.

But if there had been anybody, representing Dr. Hadwen, who was a medical man or Dr. Hadwen himself, he could have examined the heart microscopically. He could have examined the membrane microscopically, he could have examined the lung microscopically?—Yes.

And he would have had an opportunity of giving evidence upon that thereafter?—Yes.

Never mind about the Coroner, if you had been responsible, especially in the case of a medical man charged with wilful neglect of this kind, would you have any hesitation in inviting him?

Mr. JUSTICE LUSH. Is Sir William Willcox bound to express an opinion, a criticising opinion? You can comment on it to the Jury.

Sir EDWARD MARSHALL HALL. I withdraw it if your Lordship thinks that. With regard to this needle, you say it was justifiable in the case of a doctor who has diagnosed a child moribund from diphtheria. He said it was too late and the case was hopeless, that was his own evidence. Do you say it was justifiable to insert this needle for the purpose of ascertaining whether there was fluid or not?—Yes.

Surely if there is fluid in a lung even at that stage you can detect it at once by the alteration of the position of the heart?—You can in an adult, but in children it is exceedingly difficult to say for certain whether there is fluid in a chest or whether it is simply consolidation of a lung.

But if there is fluid the position is altered?—Yes.

Probably would be?—Yes.

Probably drawn downwards and towards the healthy lung?—It is pushed over by the fluid to the sound side.

So there would be no difficulty except in the case of a child. Do not you think in any event that ought to have been done before you decided to aspirate? —Sometimes it is very difficult in a child very ill to make out the exact position of the heart.

You agree that this particular bacillus is often found in healthy throats, and also in inanimate objects?—It is found in healthy throats, but in the various figures it comes to roughly 3 per cent.

And it is also found, is it not, in cases of people who are carriers, but not susceptible to the disease? —Yes, that is so.

You yourself have no knowledge of either Dr. Hadwen or his views?—No.

Re-examined by Mr. VACHELL.

As to the difficulties of diagnosing diphtheria, it is suggested, and I think you accept it, that by mere eyesight observation there may be a great difficulty in distinguishing between a case of tonsillitis and diphtheria?—Yes.

In those cases, of course, the swab and the bacteriological examination would be most useful?—The swab should be taken.

Supposing in addition to a throat in which there is membrane there are these symptoms we have heard of, the very foul breath, the discharge from the nostril, drowsiness, the headache, and the thick speech, would any of those symptoms assist one in coming to a conclusion as to what the nature of the disease was?—Yes, it would be practically certain without taking a swab that the case is one of diphtheria.

Mr. JUSTICE LUSH. In this particular case? —Yes.

Mr. VACHELL. Such symptoms as you have heard here. Does it come to this, that there may be cases of tonsillitis which are difficult to distinguish without the aid of bacteriological examination?—There may be cases, but not in this case.

Not where you have these other symptoms?—No.

About the heart, does the failure of the heart action frequently play a part in the actual death of the patient?—Yes.

Is it due to that in a large percentage of cases?—Yes, it was so in this case.

Mr. JUSTICE LUSH. Was what?—The heart failed; that was the immediate cause of death.

Mr. VACHELL. I drew attention to what Dr. Washbourn said before the Coroner on the subject of the heart. What he said before the Coroner seems to have been this: "The heart was apparently healthy, its cavities not unduly distended." I suppose the distension or not of the cavities would be something he could see without a microscopical examination?—Yes.

And would that, supposing you saw no distension of the cavities justify what he says there, that apparently the heart was healthy?—Yes, apparently the heart appeared healthy, but there is always some muscular degeneration in these diphtheria cases.

Now about the distinction between lobar and lobular. If this pneumonia in this right lung had been indeed lobar would the lung have just floated, I think that was one of the terms that Dr. Washbourn used?—It would have sunk.

Altogether?—Yes.

Is that something that one can rely on altogether. Would it not have been unable to float to the limit of extent this did ?—It is a rough test, it is not an accurate test, but it is a test that is always done.

And does the fact that it just floated assist you in coming to a view as to the nature of the pneumonia ?—Yes, it confirms my view that it was a massive lobular pneumonia.

Now about the needle used for exploring ; would any harm be done to the child by that ?—Not if it is done with due care.

Would that in any way contribute to the child's death ?—No.

Mr. Justice Lush. I do not think that has very much really to do with the case, that puncture.

Mr. Vachell. Then I really fail quite to know what my friend meant.

Sir Edward Marshall Hall. I will tell you why I put it, to show that Dr. Ellis was not so competent as he would have us believe, and that he ought to have been able to diagnose it by auscultation and not to puncture the child within half an hour of its death to see if there was fluid.

Mr. Vachell. Is there anything you would like to add before your evidence finishes ?

Sir Edward Marshall Hall. In the case of a lung that has lobular pneumonia, the lung would not be solid, of course ?—No, there would be areas containing air ; those areas would be large or small according to the extent of the lobular pneumonia.

Although there was no microscopical examination you would, of course, be able to say whether the lung was solid or not ?—Yes.

I have only just found this. Do you know that Dr. Washbourn said before the Coroner : " The right lung was red and solid throughout " ?—Yes, I know he said that. I accept that entirely. That might have been so with a lobular pneumonia if it was a very extensive one, and it was so in this case.

You say that the danger from the heart is so serious in the case of diphtheria ; what do you say about the condition of a child who on the ninth day of a diphtheritic attack of this gravity is able to walk downstairs, go and get a drink of water, and walk up again ?—I say that child was running a very great risk of dropping dead.

That is to say, if the heart was affected ?—I think the heart must have been affected because of that nine days' illness ; it must have been affected more or less.

Is not this inference also to be drawn, that having regard to the fact that she did so without assistance, the probability is as to this sudden death from the heart that she had not been so ill as you have otherwise indicated ?—No, I do not think so.

Have you ever heard of a child with diphtheria for nine days getting up and walking downstairs in her bare feet ?—Yes, many cases.

Mr. Justice Lush. What happened ?—There are many cases of diphtheria that are not diagnosed, and the children are walking about all the time.

Sir Edward Marshall Hall. But they are not serious cases of diphtheria ?—They may be.

Are they running a great risk all the time ?—Yes.

That is because the heart is invariably affected ?—The heart is invariably affected. You cannot say whether it may suddenly stop or not. It is invariably more or less in all the severe cases.

Mr. Vachell. Does it necessarily mean that a diphtheria patient must drop down dead if he gets out of bed ?—Certainly not.

It is merely that there is a risk ?—Yes.

Mr. Justice Lush. You told us some time ago that the proportion of deaths when antitoxin was administered had fallen from 30 to 40 down to 10 per cent. ?—Yes.

Does not it make a difference to the chances of recovery whether you administer this serum at once or whether you wait two or three days ?—A very great difference. If it is given on the first day the mortality is very slight, 3 per cent. in some years, and in some years the mortality has been nil.

If you administer the antitoxin on the first day the proportion of those who do not recover is 3 per cent., or even nil ?—Yes, that is right.

Take the whole of the cases where antitoxin is administered, and there are 10 per cent., how do you account for the difference between the nil and the 10 per cent. ?—Because a large number of cases that come into the hospitals arrive in the later days. Some of them arrive after the sixth day, and one, perhaps, does not give them antitoxin at all.

Sir Edward Marshall Hall. That would not come within your Lordship's question if they had not had antitoxin. He said some do not get it at all.

Mr. Justice Lush. I am taking the cases that come within the 10 per cent. You have given 3 per cent., or nil, if the antitoxin is administered on the first day. If the total number is 10 per cent., the other 7 per cent., or 10 per cent., must have had antitoxin administered after the first day, must not they ?—Yes.

Supposing you administer the serum, say the third or fourth day after the attack begins, what sort of percentage would you expect ?—I can give you the figures, if you like.

Mr. Justice Lush. I would like to know, because I have a reason for asking. This patient had diphtheria, apparently, two days before the doctor was called in.

Sir Edward Marshall Hall. Certainly two.

Mr. Justice Lush. Certainly two, possibly three. Therefore Dr. Hadwen cannot be blamed for not administering antitoxin before the second or third day, as the case may have been ?—I can give you the figures. The first day are 3 per cent., the second day about 5, the third about 6 or 7. I will give you the exact figures.

And if it is not administered at all it will be about 30 to 40 per cent. ?—Yes.

It is not a perfect and absolute cure if it is administered at once ?—No, but some cases of diphtheria are so bad, so grave, that they are practically hopeless from the first.

Are there other cases ? Take lockjaw ; do not you administer a serum for that ?—Yes.

What is the sort of proportion of recoveries there ?—In the case of lockjaw the serum has not been the great success it has been with diphtheria, because in lockjaw the poison fastens itself on to the spinal cord, and the poison has done its damage on the spinal cord before you can get your serum in. It is very valuable as a preventive, that is if a person has a wound, and that wound contains the lockjaw germs, if you give that person a dose of serum you can prevent him getting lockjaw, but if he has once got lockjaw the serum is of value, but not of anything like the great value that it is in diphtheria.

Is there any antitoxin that is more powerful as a curative than the diphtheria antitoxin ?—No, I should say it is the most certain and the most efficacious of all the sera.

STEPHEN WILLIAM WICKHAM, *sworn.*

Examined by Mr. Micklethwait.

Are you a Police Constable in this City ?—Yes.

Were you present on the 13th of September when Inspector James charged Dr. Hadwen ?—I was.

Did Dr. Hadwen say anything ?—Yes, he said : " I have nothing to say."

Mr. Vachell. My Lord, that is the case for the Crown.

Sir Edward Marshall Hall. I will at once call Dr. Hadwen.

EVIDENCE FOR THE DEFENCE.

DR. WALTER ROBERT HADWEN, *sworn.*

Examined by Sir Edward Marshall Hall.

Is your name Walter Robert Hadwen ?—Yes.

What are your qualifications ?—Doctor of Medicine, St. Andrews University ; Licentiate of the Royal College of Physicians, London ; Member of the Royal College of Surgeons, England ; Licentiate in Surgery and Medicine of the Society of Apothecaries.

How long have you been in practice ?—Something over 30 years.

I believe you have been a lifelong teetotaller ?—Yes.

And a vegetarian ?—Forty years.

You eat no meat, and you have never tasted alcohol ?—No.

Among other things, have you had experience of diphtheria ?—Yes, I have had a fair amount.

What sort of experience ; have you ever had a diphtheria epidemic to deal with ?—Years ago ; about 25 years ago I was associated with an epidemic of diphtheria at Stapleton, in Bristol, and most of the cases came under my care, and there I had, of course, considerable experience of what diphtheria really is.

Have you ever, in any case of diphtheria that you attended, administered an injection of diphtheria antitoxin ?—Never, and all my cases have been successful.

Have you ever been vaccinated ?—I have not.

The Burnham family, I think, are club patients ?—They are.

And I think you had attended them for about six months, or so, prior to August of this year ?—I understand they have been in this association about that time ; I have not attended them, as far as I know, before this time.

Was the first person you were called to see Leonard ?—Yes.

And did you go to see him on the 21st July ?—Yes, that was the first day.

What was he suffering from ?—Suffering from ulcerated tonsillitis, commonly called septic tonsillitis.

Was there any discharge from the nose ?—None whatever.

Did you notice any foul smell from his breath ?—None.

Was anything said by the mother to you as to there being a foul smell ?—Not a word.

Did you attend him on four successive days, and twice afterwards ?—On the 21st, 22nd, 23rd, then the 25th, and finally the 28th.

That is five days ?—Yes.

Mr. JUSTICE LUSH. That is July ?—Yes.

Sir EDWARD MARSHALL HALL. What did you give him ?—I gave him a saline mixture, ordered gargles of vinegar and hot water, and when he had recovered from his tonsillitis I gave him a tonic.

And we know that he got well ?—Perfectly well.

When do you consider, first of all, he was well of the tonsillitis ?—Roughly in about four or five days.

Did you see him again after you gave him the tonic ?—Yes, I saw him several times whilst I was attending the deceased child.

And during that time was he running about the place, and did he seem all right ?—Yes, perfectly.

Is the gargle of vinegar and water a thing you have often employed ?—I have employed it in thousands of cases, and always successfully.

Is vinegar what is called acetic acid ?—Yes, it is diluted. It is recognised in the British Pharmacopœia.

British Pharmacopœia, or no British Pharmacopœia, has it proved, in your hands, an efficacious gargle ?—Unquestionably.

In this case did it prove efficacious ?—Undoubtedly.

Did you suspect at all the possibility of diphtheria in this case ?—Yes.

Mr. JUSTICE LUSH. In which case ?—In Leonard's case.

Mr. JUSTICE LUSH. Would you mind asking him if he did in Leonard's case ?

Sir EDWARD MARSHALL HALL. It is still Leonard's case. You did not rule out the suspicion of diphtheria ?—No.

And did you satisfy yourself whether it was diphtheria or not ?—Absolutely.

Sir William has told us that acute tonsillitis and diphtheria are often indistinguishable in an early age, except by a swab ?—I do not accept that at all. The great and general distinction between tonsillitis and diphtheria is this, that tonsillitis is confined to the tonsils, whereas diphtheria always appears upon the uvula, or the soft palate. In addition to that, tonsillitis invariably affects both tonsils, but in the majority of cases in diphtheria only one tonsil is affected. In addition to that, one of the very earliest signs of diphtheria is an enlargement of the cervical glands, and in every case of genuine diphtheria which I have attended the face has been practically square, square jaws. In tonsillitis there may be a slight enlargement of the glands, but very slight indeed. The really pathognomonic sign of diphtheria is this, very considerable enlargement of the cervical glands, very tender, and beginning at an exceedingly early stage.

Was there anything you might have done, short, of course, of taking a swab, I am not dealing with that, in forming the diagnosis of Leonard, which you did not do ?—No, not one single thing.

What was your diagnosis in Leonard's case ?—Ulcerated tonsillitis.

Was there even sufficient doubt in your mind to indicate the advisability of taking a swab ?—None whatever.

Having regard to the way in which Leonard got well and the course that his illness took under your treatment, what do you say now, was he suffering from diphtheria ?—Certainly not, not a vestige of it.

On the 28th I understand the evidence is that Mrs. Burnham brought little Gladys to your surgery ?—Yes.

Were you told how long she had been ill ?—I do not remember.

What was the matter with her ?—Simply a slight tonsillitis, very slight indeed. I may say that Leonard had the worst throat of the three children.

What did you do for Gladys ?—Simply ordered the same as for Leonard.

Were you asked by the mother to look at Gladys again at all ?—No, I do not think I was. The child began to run about the streets and was running about at the time I was attending the other child.

Mr. JUSTICE LUSH. How soon did Gladys begin to run about ?—Well, she never went to bed.

Sir EDWARD MARSHALL HALL. Had you or have you any suspicion that Gladys ever had diphtheria ?—I am sure she never had.

That was the 28th. What day was it that you were asked to go and see Nellie ?—August 1st, a Friday.

Did you go ?—I went ; I reached there about a quarter past one in the morning.

Were you told how long the child had been ill ?—Yes, the mother told me that the child had been ill for two days.

Before you saw the child, had the mother given you any description of her symptoms ?—No, nothing but that the child had a sore-throat.

When you got there, was the child in bed ?—Yes.

Tell my Lord and the jury what you did. Was Leonard in bed ?—No.

Leonard had not been in bed ?—No.

Nellie was in bed ?—Nellie was in bed.

What was the first thing you did ?—The first thing I did was to examine the throat.

Tell my Lord and the jury how you examined the child's throat ; what did you do ?—I told the child to open its mouth, draw in its breath and say "Ah," and when you do that with a child you can generally see the whole of the throat with very little difficulty, and I simply put my finger upon the tongue just to press it down—she raised it slightly—and thus of course had a good sight of the tonsils.

What did you find ?—So much has been made about my putting my finger in the child's throat that perhaps I may, if you will allow me, say that I consider the finger is the best tongue depressor you can possibly have. When I examined the throat, I found there were three follicles, three ulcerated spots upon the right tonsil and there were two upon the left. The throat was very red, and I just made the remark, "It looks very much like a scarlet fever throat," and I carefully examined the body in order to see if there was any rash. I found no rash and, considering the time the child had been ill, if it had been scarlet fever there would have been a rash. I then noticed that the child had a watery discharge from the nose, in fact the child had a bad cold. I then examined the chest stethoscopically and I found a little harsh breathing which pointed to a slight bronchial catarrh and I fancied there might have been a suspicion of broncho-pneumonia.

You say you had a suspicion of it ?—I had a suspicion ; I thought it from percussing one or two spots. I then ordered an expectorant mixture for the child, vinegar and hot water for the child to gargle the throat, and just a few general directions.

It is said you never took her temperature or felt her pulse ; what about that ?—The statement is quite untrue.

What did you do ?—I felt the pulse the very first thing as I always do ; it is part of the general routine of a medical man's practice.

From the pulse can the doctor diagnose very often other conditions ?—Yes.

From the pulse did you diagnose any feverish condition or what ?—From the pulse I found that the pulse was rather quicker than normal, and I then took the temperature and found it was 100°.

Would the taking of the pulse necessarily be visible to the mother when you took it ?—It might have been. I will not be quite sure that it would be, because I find with children it does not do to make much fuss with them, and I would just simply put my hand on its hand and, without letting it know what I was doing, I just grip the pulse and look at the throat at the same time and humour the child.

Is it any longer necessary to go through the old-fashioned paraphernalia of taking out a watch ?—No, not for that.

Experienced medical men can tell approximately without a watch ?—Yes.

The temperature was 100°, the pulse was a little faster than normal and you prescribed this expectorant medicine. Where was that to come from ?—From the surgery.

You had also prescribed the gargle ?—Yes.

How long were you there, should you think, on the first occasion ?—I should think roughly about eight or ten minutes.

Did you in any way unduly hurry your visit to the detriment of the child ?—Certainly not.

Mr. Justice Lush. The mother says you were only there three minutes on each occasion ?—That is absolutely untrue.

Sir Edward Marshall Hall. You were there about ten minutes ?—I should think about ten minutes.

Anyhow, did you make a careful examination ?—I did.

And your diagnosis was what you have told us, that the child had tonsillitis ?—Absolutely.

Had you any suspicion of diphtheria ?—None whatever, though I had it in mind as one naturally would.

I suppose in every case of sore-throat you must have diphtheria in your mind ?—Certainly.

When you first saw this child, was she well-nourished or poorly nourished ?—She was a very poorly nourished, ill-conditioned, weakly child with sore eyes, what we generally call a strumous condition.

Mr. Justice Lush. What age was she compared with the other two ?—The boy was 14.

How old was Gladys ?—Six and this one was 10.

Mr. Justice Lush. She came between the two.

Sir Edward Marshall Hall. Nellie came between the two.

Mr. Justice Lush. And were the other two healthy robust children or not ?—No, they are all weakly children.

Sir Edward Marshall Hall. Under the rule of the club, as the mother has told us, can anybody send for you at any time if it is urgent ?—Any time whatever.

Mr. Justice Lush. If you do not mind my suggesting it, before you pass from the first visit, would you ask about the yellow discharge ?

Sir Edward Marshall Hall. I will ask that specifically. On the first visit did you see any yellow, blood-streaked discharge from anywhere ?—None whatever.

Mr. Justice Lush. You are quite sure of that ?—Absolutely positive.

Sir Edward Marshall Hall. Did you see any membrane or membranous diphtheritic matter in the throat ?—Not a shred of it.

Did you notice any offensive breath as far as Nellie was concerned ?—None whatever.

Did you notice whether she was particularly drowsy ?—She certainly was not drowsy.

Not at that first visit ?—No.

Did the mother ever point out to you a yellow-red discharge ?—No.

Never said a word to you ?—No.

Or did she ever say a word to you about her bad breath ?—Not a word from first to last.

You were not sent for between the 1st and the 4th, but on the 4th you went again on your own accord ?—Undoubtedly.

Mr. Justice Lush. The mother did not ask you to go again ?—No.

Sir Edward Marshall Hall. What about these ulcerated spots ?—On the 4th when I called the three spots had coalesced, and so had the two ; they were quite small, and apparently were already diminishing. I was very pleased with the condition of the child.

Mr. Justice Lush. Are you referring to the spots ?—On the tonsils.

Are they the spots on the throat you can see ?—Yes, on the tonsils. I was also pleased to notice that there had been no spread whatever to the uvula or the soft palate ; simply these spots upon the tonsils themselves. The throat was still very red. Then I did not use my stethoscope on this occasion, I used direct auscultation, that is, I put my ear to the child's back, and examined its lungs, and I found that the bronchial catarrh had completely cleared up. I saw no watery discharge from the nose. The child was better in every way, and I told the mother on that occasion that I was most pleased with the progress it had made.

Sir Edward Marshall Hall. You said that the throat was still very red ?—Yes.

If this had been a diphtheritic throat would you have expected to find it red, or some other colour ?—No, it would have been a very pale colour. That is one of the most distinctive signs between tonsillitis and diphtheria, that is of the very pale mucous membrane in the case of diphtheria, but a bright red in the case of tonsillitis.

Did you find, on that occasion, very offensive breath ?—No, none whatever.

And did you see any sign or vestige of membrane ?—None whatever ; it had not spread to the uvula, or the soft palate at all.

Did you change the medicine, or let her continue ?—No, I told her to continue the aperient medicine, and to continue the gargle of vinegar and hot water, when she told me that the child could not gargle very well ; it could not get the gargle back far enough, were her words.

Was that the Monday, or the Wednesday ?—This was on the Monday.

Mr. Justice Lush. What date was this ?—The 4th.

Sir Edward Marshall Hall. What did you tell her ?—I then told her to apply some glycerine with a feather over the tonsils.

How long did you stay on the Monday ?—Roughly, about the same time.

About ten minutes ?—I should think so.

Did you stay a sufficient time to enable you to do justice to the patient ?—Certainly.

Then did you come again of your own volition on the 6th, the Wednesday ?—Yes.

What was the condition of the child then ?—On the Wednesday I may say that when I entered the house I met the mother at the bottom of the stairs, and I said : " Well, how is the little one this morning ? ", and she replied : " Oh, it is very much better," and when I went upstairs into the bedroom

I found that to be correct. The child was sitting up in bed, and smiling, and seemed better altogether. There were no further signs of the cold or cough. The right tonsil was completely clear. The left tonsil was nearly clear, only a small pin-point left. There was no membrane upon the uvula or the soft palate, and the child was so much better altogether that I said to the mother: "You need not give any more of the mixture; I will let you have a tonic. The child is so weakly that it needs strengthening up."

Did you, in fact, prepare a tonic for her?—I did. I gave her a mixture of syrup of phosphates, and she sent down for it, and the child had it.

Did you take the child's temperature on the 4th?—No, I did not take the child's temperature either on the 4th or the 6th, because I found the pulse quite normal, and it was unnecessary.

You did feel the pulse?—I took the pulse on each occasion I went there.

Was the child weak on the 6th when you saw her?—Yes, very weak. She was a poor weakly child.

And she was in bed?—She was in bed.

You did not come again until the 9th, did you?—Until the 9th.

Then you were sent for?—I was sent for, but I was coming. As a matter of fact I had it booked for Friday, but I was so exceedingly busy I could not reach there, and it was not an urgent case, I considered, so I did not go.

Mr. Justice Lush. But you were going?—I was going on Friday. I had it marked out in my book for the 8th, but I was so exceedingly busy with some urgent cases that I could not very well go, and I therefore went on the Saturday morning. Just as I was going the little boy I had cured of tonsillitis came down and said: "Mother said will you come up as soon as you can and see Nellie, because she has been taken very much worse." I said to the boy: "I am just coming," and I went. I was there about five minutes past 10.

Sir Edward Marshall Hall. What did you find?—I was thunderstruck at the change in the child. The child was breathing rapidly, and was lying in the most listless manner, quite contrary from what I had left it on the Wednesday, and I turned to the mother to find out what was the meaning of it. The mother said it had been taken with vomiting early on the previous morning, that was on the Friday. She said it had been vomiting the whole of the day. She said it could not keep down either its milk or its medicine, and I saw at once that the child was in a serious condition. I first examined the throat, and I made the remark that has been quoted: "The throat has cleared up nicely." There was not a vestige of ulceration upon the tonsil. There was no membrane either upon the uvula or the soft palate. The throat was perfectly clear, as clear as the palm of my hand. I then examined the chest, and I found that in the right lung the breath sounds were deficient, and I concluded that the child had pneumonia. The left lung was quite clear. The air was coming through well, and I turned to the mother and said: "Well, I think she will pull through all right," because having had a very long experience amongst children I know this, that you can never give a child up until the last gasp, and it had one good lung, and I saw no reason why it should not, perhaps, providentially, get right again. At the same time, it was in a very serious condition. I took the temperature, and I found it was 101°. The pulse was 120. I then said to the mother, "Well, there is only one thing, and that is you must give milk as often as ever you possibly can; give it cold, because that is more digestible, but do keep milk going as much as ever you possibly can. It is the only thing to save the child." This is to keep the strength up in order to battle against the disease. The mother said: "What about the medicine?" Well, in a case of this sort, of course, medicine was very little use. I said, "Well, dilute it with water, and just give that if you can," not that I felt the medicine would be of any value, but that it might help her to take the milk, but keeping up the strength was the point that I felt was to be done.

On that day, the 9th, did you see any discharge from the nose, or from anywhere, of a yellow colour stained with blood?—None whatever.

Did you at any time during the course of your visits to this child ever see any yellow discharge stained with blood?—None whatever, from first to last.

Were you ever told by anybody, Mrs. Burnham, or the sister, or anybody else, that there was a discharge of that character?—It was never mentioned.

Nor was your attention ever called to it?—My attention was never called to it.

Mr. Justice Lush. Were you quite close to the child's breath when you were examining the chest, you must have been?—Yes, one would be.

Did you notice any offensive smell?—No, none whatever, not but what, of course, with septic tonsillitis very often you do get a foul breath, but I did not notice anything here, and my nasal organs are fairly acute.

Sir Edward Marshall Hall. You are 70 years of age, I think?—I am 70 years of age.

They are quite acute, in spite of your 70 years?—Yes.

Did you ever tell the mother on that occasion, or anybody else, that there was nothing the matter with the child whatever?—Certainly not, it would have been a most absurd statement.

Mr. Justice Lush. That impressed me very much, of course, and no doubt the Jury. The mother said it was on the 9th the doctor said that, and, of course, the child, on the evening of the 9th, was dying?—With the conditions that the mother told me the child was suffering from it would naturally have been an impossibility, with the child in front of me, to have made any such observation; it is too ridiculous for words.

Sir Edward Marshall Hall. How long did you stay on that occasion?—I stayed a fairly good time. Of course, I cannot say exactly, but I made a very thorough examination. I was very much alarmed, and taken aback, and I tried to find out from the mother what was the meaning of it, but I could get nothing from her about it.

It is admitted, so that there is no reason for my not putting it to you, that the mother never told you that the child had been downstairs on the night of the 7th in her bare feet to get a drink of water?—No, she did not.

If she had told you would you have attached importance to it?—Most decidedly I should.

Was what you saw then consistent with the result of a chill caught by the child at or about that date?—Certainly; something I saw had seriously happened between the Wednesday and the Saturday, and it was a mystery to me as to what it was that had happened.

Do not give me any details, but tell me if you can, when was it that you first knew that this child had been downstairs on the 7th under the conditions we now know of?—It was several days after the inquest had been held.

Mr. Justice Lush. I suppose it was proved at the inquest?

Sir Edward Marshall Hall. Yes, it was afterwards?—At the adjourned inquest.

Mr. Justice Lush. The mother gave evidence on the first day, did not she?

Sir Edward Marshall Hall. Yes, but she was recalled.

Mr. Justice Lush. Did not she mention it on the first day?

Sir Edward Marshall Hall. Not a word till she was cross-examined by my learned friend Mr. Clements on the 12th September, a month afterwards. Further than that, if your Lordship looks, she was asked if she knew of anything that had happened, and she said she knew of nothing. Then my friend put it specifically to her, and she admitted it. (To the Witness.) In the normal course of events, having regard to that child's condition, when you saw her on the morning of the 9th, when would you have gone again to see the child?

—I should have gone again the same night, and I intended to do so.

At about what time was it that the telephone message came through ?—Just about nine o'clock. I had just come in from seeing a case, and just as I opened the front door the telephone bell rang, and I went to it.

We have heard what Mr. Fudge says. Is that fairly accurate ? Will you tell us what did take place ?—Some man spoke, and the first words were : " I am speaking with regard to Nellie Burnham." I said : " Who is that ? " He said : " Nellie Burnham, 49, Vauxhall-road." I said : " Yes." He said : " I am very dissatisfied with your treatment of her." I just remarked " Yes," and he said : " I want to have another doctor." I said : " But the child has been going on exceedingly well until this morning." He said : " I do not agree with you ; I am thoroughly dissatisfied with your treatment, and I am going to have another doctor." Then he added : " Have you any objection ? " I said : " Well, we live in a free country, of course you must please yourself," and he then said : " Well, I am going to call one," and I said : " Very well," and with that the telephone message closed.

Were you ever told on the Sunday by anybody that the child was dead ?—No.

Did you know on the Monday ?—No.

Did you hear it on the Tuesday ?—No.

When did you hear it ?—I heard it for the first time on Wednesday, an hour and a half before the inquest was held.

Who communicated with you ?—Some young man from the Coroner's office.

Until you heard that, did you know that the child was dead ?—I did not ; no idea.

Had you had any notice prior to this that there was going to be an inquest ?—None whatever.

Had you had any notice that there was going to be a post-mortem examination ?—None whatever.

If you had had notice that there was going to be a post-mortem examination and that your conduct was called in question, would you have asked to go to the post-mortem examination ?—Certainly I should.

Or been represented ?—Certainly I should.

What day was it the inquest opened ?—On the Wednesday.

And you heard of it an hour and a half before ?—I heard of it an hour and a half before.

Did you ever have any sort of communication of any kind whatsoever from Dr. Ellis ?—None whatever.

Did you yourself go to the inquest ; did you attend the inquest ?—Yes, I did.

And you heard the evidence ?—I did.

From the evidence given by Dr. Washbourn—— ?—No, you are speaking of the first inquest.

The only evidence then was that of Mrs. Burnham, the mother, and Dr. Ellis. Then it was adjourned, we know, with no evidence, and then finally adjourned until the 12th September when my friend Mr. Clements represented you ?—Yes.

You have heard all the evidence in this case, both before the Magistrates, before the Coroner, and in this Court ?—Yes.

First of all, what do you say, is it possible in your opinion to distinguish between diphtheritic membrane and other membrane when it was found by Dr. Washbourn without microscopical examination ?—You cannot be sure it is diphtheritic membrane unless you do microscopically examine it.

Whatever may be the exact effect of that, did you ever see any membrane such as it is suggested by Dr. Washbourn you must have seen ; did you ever see any membrane in the dead child while it was alive ?—No, none whatever.

Of course, you never saw the post-mortem examination ; you did not see the lungs or anything ?—No, I saw nothing at all.

Then you had a communication from Dr. Washbourn, and you heard Dr. Washbourn say it was lobar pneumonia ?—Yes. I may say I was very indignant at the inquest when I found that a post-mortem examination had been held the day before and I had not been invited, and the Coroner said : " Well, you shall see the child yourself. Is there a medical man whom you would like to attend with you," and I mentioned a medical man whom I should like to be with me on that occasion. When I got outside I said to the Coroner : " Well, now, about this post mortem, can we fix it up ? " and Dr. Washbourn said : " It would not be the slightest use : all the organs are cut to bits, and you would not be able to distinguish anything."

Mr. VACHELL. I wish you had asked that of Dr. Washbourn.

Sir EDWARD MARSHALL HALL. I was not instructed about it, and I do not see the importance of it. Anyhow, you never had an opportunity of seeing any of the dead body of the child ?—None whatever.

What is the kind of pneumonia that is a sequela ordinarily of diphtheria ?—Lobular pneumonia.

What do you say about the possibility or the ability, I should say, to distinguish between a lung that was affected by lobular and lobar pneumonia ?—I think any experienced person can distinguish by the naked eye the difference between lobar and lobular pneumonia in a post-mortem examination.

With regard to the condition of the heart, what do you say about that ; would an ordinary experienced post-mortem doctor be able to state whether the heart was normal, or not, on the view ?—Certainly, the colour is quite sufficient to distinguish it.

In the case of your attendances upon this child Nellie, was there anything you left undone that you ought to have done, or was there anything you did you ought not to have done, to your knowledge ?—No, nothing whatever.

And to-day, in spite of the evidence that has been given, what is your own opinion as to what Nellie was suffering from ?—She was suffering from ulcerated or septic, as it is called, tonsillitis, and she had lobar pneumonia, which was in my opinion responsible for her death.

Sir EDWARD MARSHALL HALL. Before your Lordship adjourns, I want to say this, that I have medical men, but my present intention is not to call any other witness but this gentleman. If by any reason of cross-examination I am forced to call them I still have the right so to do, but as at present advised I do not intend to call any other witness except this gentleman. So, therefore, if that is so, my learned friend would cross-examine and I shall probably have to re-examine.

Mr. JUSTICE LUSH. Very well.

Mr. VACHELL. Sir William Willcox has now marked the statistics which your Lordship wanted.

Mr. JUSTICE LUSH. Do those statistics bear out what you told me ?

Sir WILLIAM WILLCOX. Yes, my Lord.

Mr. JUSTICE LUSH. If you tell me that, that is all I want to know.

Sir WILLIAM WILLCOX. Yes, they do.

(*Adjourned to the following morning at* 10.30.)

Wednesday, 29th October, 1924.

Mr. JUSTICE LUSH. The discharge from the nose or throat and nose was not mentioned by the mother before the Coroner on the first day, was it ?

Sir EDWARD MARSHALL HALL. Yes, I think the discharge was mentioned.

Mr. VACHELL. Yes, it was.

Sir EDWARD MARSHALL HALL. But never that it was pointed out to the doctor, but she said it did exist, that is my recollection. We will look at it.

Mr. JUSTICE LUSH. Mr. Clements will look it up.

Mr. VACHELL. Your Lordship will find that in the examination by Mr. Haddock of Mrs. Burnham, the mother, on the first day : " I have a child named Leonard." Then at the end of the examination your Lordship will find this : " All three children had a discharge from the nose of a greenish colour with a little fluid in it."

Mr. JUSTICE LUSH. Was that the evidence given on August 1st ?

Mr. VACHELL. It is speaking of all three children she had, including the deceased.

MR. JUSTICE LUSH. It does not say in terms that that discharge was noticeable on the 1st August.

MR. VACHELL. No, I do not think attention was drawn to that; there is no distinction made.

MR. JUSTICE LUSH. It is a very important date for reasons I will point out later.

MR. VACHELL. Yes, my Lord, I quite understand that.

DR. WALTER ROBERT HADWEN, *recalled.*

Cross-examined by MR. VACHELL.

You have, I suppose, considered the efficacy of antitoxin as a remedy in cases of diphtheria?—I have.

Have you consulted statistics upon the subject?—I have.

Apparently you have furnished my learned friend, Sir Edward, with a copy of the statistics of mortality?—A few.

And you heard Sir William Willcox cross-examined about them?—I did.

Did you hear him correct certain errors that Sir Edward apparently had made in dealing with those statistics?—I did not.

Do you agree that the statistics show that since the introduction of antitoxin there has been a very susbtantial decrease in the mortality from diphtheria?—That all depends what kind of statistics you are dealing with. The statistics that Sir Edward Marshall Hall presented to the Court were the statistics of the Registrar-General. The statistics which Sir William Willcox gave to the Court were the statistics of the Metropolitan Asylums Board.

Do you know that Sir William Willcox dealt also with the statistics of the Registrar-General?—He made a few comments upon them, but he did not deal with them.

Did he give the results to the Court yesterday?—He simply commented upon the statistics which Sir Edward Marshall Hall presented.

Did not you hear Sir William Willcox in his evidence say that the statistics of the Registrar-General showed a decrease of at least 30 per cent.?

MR. JUSTICE LUSH. It is somewhere about that.

MR. VACHELL. I will accept that. Did you hear that?—I cannot say that I remember that. Perhaps my mind was concentrated upon what were the real facts of the case.

Did you hear him say that those statistics show that the death-rate in 1893 was 389 per million and that by 1923 it had been reduced to 71?—That was a single year.

Did you hear him say that?—I heard him say that, yes.

Do you accept the returns of the Registrar-General as being accurate?—I do.

And you observe that they were not challenged when Sir William Willcox had given his explanation of them?—Quite true.

Do you believe in the efficacy of antitoxin?—No, I do not; I consider it a useless and dangerous remedy.

You have said that you heard also the figures of the Hospital Boards in London dealt with. Do you agree that those show a very substantial reduction in the mortality where antitoxin has been administered?—They do, but I consider them a very unscientific collection of statistics.

You say you do not believe in it?—That is so.

Then you, I suppose, have never administered it yourself?—I have not.

Never given it a trial?—I have not.

Do you believe that it is right for anybody else to administer it?—Each one must act according to his own conscience.

Would you mind answering it a little closer? Do you think if any other medical man administers antitoxin he is doing a right or a wrong thing?—It depends entirely upon his own conscience. Each medical man must act as he feels to be right.

I am asking about your conscience; what do you think?—I am not going to give any answer to such a question.

Would you willingly allow any patient who was suffering from diphtheria, any patient of your own, to be treated with antitoxin by another medical man?—Not if I could help it.

Would you do your best to prevent it?—I would.

And you have, have you not, published articles and pamphlets in which you have attacked the whole system?—I have.

And scathingly referred to the practice of using it by medical men?—I have.

How many cases of diphtheria have you had amongst your patients in the last three years?—During the last three years I doubt whether I have had any at all; I cannot call to mind any.

Not any?—I do not think so.

There has been diphtheria in Gloucester during those three years, has there not?—Well, I daresay there have been some notified. I do not know that I have read the Medical Officer's report on the subject.

200 or 300?—Yes.

Have you notified a single case yourself?—Of course I am only speaking from mere memory. So far as I remember I do not think I have notified a single case during the last three years.

When a case of diphtheria is notified to the Medical Officer of Health, does he at once take steps to have the patient removed to an isolation hospital?—I cannot say.

Is that what is generally done; you know that?—It all depends. I have had a fair number of cases since I have been in practice in Gloucester in which the Medical Officer of Health has allowed me to treat the case at home.

How long ago was that?—That I cannot say.

Try, in years. I do not want to pin you too closely to a number of years?—I really cannot say.

The isolation hospital exists, does it not?—Certainly.

The Medical Officer is there?—Certainly.

Is it one of his duties to remove——

SIR EDWARD MARSHALL HALL. I must object to that question; there is no compulsion to remove, either for fever or diphtheria.

MR. VACHELL. My friend answers the question for you. Is it the practice of the Medical Officer of Health to remove these cases, if he possibly can, to the isolation hospital?—I believe it is, unless there is sufficient room for isolation at home.

To an infectious diseases hospital I think they call it, and is one of the first steps that he takes to administer the antitoxin treatment?—I have heard so.

This was a small house, was it not, where the Burnhams lived?—Yes.

And a family of children, four or five. Three of them have been mentioned, but there is another?—I think there were four children altogether.

Have you any doubt at all that if you had notified this case to the Medical Officer of Health—I am assuming, of course, that you thought it was diphtheria—that he would have taken steps to get these children removed to the infectious diseases or isolation hospital?—Considering the condition of the house I would have suggested that the child should have been removed myself.

But at any rate if you had reported it, you have no doubt the child would have been removed?—Undoubtedly.

SIR EDWARD MARSHALL HALL. He said more, "And I myself should have advised it."

MR. VACHELL. Do you doubt that if those children had been removed that they would have had the antitoxin treatment at once administered?—Of course I do not know what is done there; I have only heard that they do administer antitoxin.

You do not doubt that that is the first thing that would have been done, do you?—I cannot say. I do not know a bit what they do there; I have only what I have heard.

What do you think?—It is very likely that they would, such is the fashion of the time.

Do you think for one moment that they would have abstained from that treatment ?—I think it is very probable that they would have administered antitoxin.

And that, I take it, would have been not only against your views but against your conscience ?—It would.

Mr. JUSTICE LUSH. Why ? What is the distinction for this purpose between your views and your conscience ; I do not understand.

Mr. VACHELL. The views are he would not administer it himself because of his views, and his conscience tells him to do all in his power to prevent other people administering it. That is so, is it not ?—No, not exactly. My conscience is that which tells me to do what I believe to be right before God. I have nothing to do with other people.

And to try and make other people do what you think ?—Undoubtedly I should persuade in every legitimate way other people, as you would, to fall in with my views.

Am I right in saying—I think you have already told me—that you not only would refrain from applying this yourself but you would do all in your power to prevent anybody else applying it ?—To persuade other people not to do it also ; there is no question of compulsion.

And to prevent them if you could ?—It depends what you call prevention ; yes, I will admit that, because I quite agree that I consider the whole system ought to be stopped.

Mr. JUSTICE LUSH. I wish you would clear up that difficulty which your question raised in my mind. If a doctor's view is that antitoxin is a bad thing for a child, there is no question of conscience ; that is his view. If his view is it is a good thing you do not suggest his conscience would tell him still not to do it. Will you tell me what that means. What do you mean by saying as a matter of conscience you would not allow it to be administered ?—Because conscience is that which tells a man whether his acts are right or whether they are wrong.

But right in what sense ; do you mean whether antitoxin is a successful remedy, or do you mean something else ?—No, because I consider antitoxin a very dangerous remedy.

Your view is that it is not a safe and proper remedy ? —Undoubtedly, therefore my conscience would not allow me to make use of it.

Mr. VACHELL. You made some reference to it conflicting with the views of God in your opinion ?

Mr. JUSTICE LUSH. That is what puzzled me ; I want to know.

Sir EDWARD MARSHALL HALL. I did not think he said that.

Mr. JUSTICE LUSH. What do you mean ; the duty of a doctor is, I suppose, to do his best for the patient, is not it ?—Undoubtedly.

How does conscience, apart from a man's conscience telling him to do what is best for the patient, operate on your mind in these matters ?—I can only say that conscience is, so far as I understand it, that principle implanted in man which leads him to decide before God what is right and what is wrong, and therefore for me to give anything which I believe to be wrong would militate against my conscience as before God.

Mr. VACHELL. You go further than that, surely. Not only do you practise for yourself what you think is right, but you endeavour to prevent other people practising what you think is wrong ?—It depends in what way you use the word " prevention." I have written, as you rightly say, a good deal upon this subject. I have not advocated compulsion in any way whatever, but I do seek in every way in my power to urge other people that they shall not adopt that which I do not believe in.

And anything that you could do to prevent antitoxin being applied you would do ?—Certainly.

Mr. JUSTICE LUSH. On what grounds, that is what I want to understand ?—Because I consider it is both useless and dangerous.

Have you had a case in which you have found it worked out disastrously to the patient ?—No, but I know of cases in others. One of the very earliest cases was that of Dr. Langerhans, of Berlin, who injected antitoxin into his own child and it was dead in three minutes.

How long ago was that ?—I forget the date, but it is quite a historical note.

Mr. JUSTICE LUSH. I wish you would pursue this, Mr. Vachell, because I want to understand it.

Mr. VACHELL. You can understand, I suppose, the difference between holding and practising your own views, and the sort of missionary work of trying to persuade everybody else ?—Certainly.

You come in the latter class ?—I am in both classes. As a medical man I refuse to have anything to do with antitoxin. As the President of the largest antivivisection society in the world I do everything in my power to urge other people to follow in the steps that I pursue.

And one step further. I have put it several times, and I think it is necessary. You go further than that. I put it to you that you would do all in your power to prevent antitoxin being administered to any patient ?—Yes.

Mr. JUSTICE LUSH. What has antivivisection to do with antitoxin ?

Mr. VACHELL. Because it is a culture from a horse, this antitoxin.

Mr. JUSTICE LUSH. What light does that throw upon the question whether it is a dangerous or useful remedy ?

Mr. VACHELL. I do not know.

Mr. JUSTICE LUSH. What does it ?—The relationship between all these inoculations and vivisection is that all these inoculations are based upon experiments on animals.

Is that why you object to them ?—Oh dear, no. I object to antitoxin quite independently of that as a medical man ; I am speaking of my two characteristics, one as a medical man, and one in my public capacity in another direction.

Mr. VACHELL. In one of your pamphlets on this very subject of diphtheria antitoxin do you say this : " If people are able to believe that these weird and cruel methods of treating disease can be of any possible service one can only admire faith's response to a very big demand." That, I think, is one of the passages ?—That is quite correct.

Is diphtheria, in your opinion, an easy disease to diagnose ?—With care.

Mr. JUSTICE LUSH. Do you mean with care it is difficult, or easy ?—Easy, with care.

Mr. VACHELL. Nothing easier in the world, is there ?—It is quite easy to diagnose diphtheria.

Did you say before the Coroner : " It is quite easy to diagnose diphtheria, nothing easier in the world " ? —Yes, with care.

You did not say with care, but I have no doubt care is always necessary ?—I have a reason for giving that answer.

There would be no difficulty in your case in diagnosing it ; I mean you would have no difficulty, would you ?—I should certainly exercise care in the matter.

We have had certain symptoms spoken to here, and I would like to ask you something about them. Is one of the symptoms of diphtheria a thickness in speech ?—Yes.

Indicating trouble in the throat ?—Yes.

Another one sore-throat, possibly part and parcel of the other ?—It depends what you call a sore-throat. In tonsillitis the throat is very sore. In diphtheria, so long as the membrane does not cover the fauces there is not much soreness, and not much difficulty in swallowing.

Is a discharge from the nose of a yellowish-greenish character if tinged with blood one of the usual symptoms ?—Not one of the usual symptoms, but it does occur occasionally.

It is a symptom ?—Yes.

Mr. JUSTICE LUSH. Do you mean you notice a discharge tinged with blood with a child suffering from what shall we call sore-throat; would you, or would you not, suspect that it might be diphtheria?—One would always keep that in mind, of course.

I did not ask that quite; I asked you something more than that. Of course you would always keep it in mind. Would you say to yourself, if your patient was complaining of sore-throat, and had a discharge with streaks of blood in it: "I must see if this is diphtheria"?—I should certainly look with suspicion upon a thing of that sort.

Mr. VACHELL. And if the nose is affected by the diphtheria you always get that discharge, do not you?—Yes, I think one would say that you would.

Is a very foul and peculiarly foul breath one of the symptoms of diphtheria?—That is not by any means common. The foulest breath is really found with septic tonsillitis.

Is there a characteristic offensive odour about the diphtheritic breath?—I do not consider so, but I have heard that said in Court.

Have you never heard it said anywhere else?—No, I do not know that I have.

At any rate, you cannot detect the difference?—No, I do not set any store upon that point.

But the foul breath is, is it not, a very usual accompaniment of diphtheria?—I do not know that I have ever noticed any particularly foul breath. Of course, under those conditions the children's stomachs are often so very much out of order that they may get a foul breath from that cause, not necessarily from the diphtheria itself.

If there is membrane there is no doubt about that?—No, it all depends. When the membrane begins to slough then you get an odour very often, unless you keep such a thing as vinegar and water going frequently, and then you do not have the same extent of foul breath.

If you see membrane in the throat, that is a very strong symptom of diphtheria, is it not?—Undoubtedly, that is on the uvula, the fauces, the soft palate.

Mr. JUSTICE LUSH. That is a strong indication, is it?—Certainly.

Mr. VACHELL. Is there membrane in every case of diphtheria?—You cannot have diphtheria without membrane, because that is really what the term implies.

Does the bacillus of diphtheria sometimes give an exudation without, in the first place, forming membrane?—I do not know that the bacillus produces an exudation, but there is an exudation before the membrane forms.

Is it not the fact that that is always the case, there is always first the exudation?—Of course, there must be. The membrane is nothing but the consolidation of the exudation.

And does that consolidation, or I use the term we are all using, membrane, take about 24 hours to form after the exudation has commenced?—It is a variable time, sometimes it forms very rapidly, and sometimes it is slow in forming.

And the exudation, before the membrane has formed, gives the appearance of rawness, does it not, to the parts affected?—I would hardly say that, because we look upon rawness as that of a red colour, whereas the mucous membrane in diphtheria is of quite a pale mouse colour.

Has it the appearance of being inflamed, the affected part?—In diphtheria, do you mean?

Yes, before the membrane forms?—No, it does not.

You have spoken about the colour. Is it not the fact that it is only in very severe cases that the exudation patch has a greyish appearance?—In severe cases?

Yes, only in severe cases?—I would not say that. The fact is the membrane changes colour very considerably. You sometimes have the membrane quite white, a pale yellow wash-leather colour, sometimes dirty grey, and so on.

What I am putting to you is something in addition to that. Is it not a fact that the throat, not the membrane, but the affected part, before the membrane forms, only takes a greyish colour in very severe cases?—I do not think so at all.

Mr. JUSTICE LUSH. Would you mind asking Dr. Hadwen to tell us what he does consider are the indications of diphtheria, that is to say, the symptoms of it? You have asked him certain things?

Mr. VACHELL. Yes. There was another important one to deal with first, and then I will come to your Lordship's question. (To the Witness.) Does diphtheria also affect the air passages of the nose, the nasal air passages?—If the mucous membrane is swollen sufficiently it does.

And does that result in a yellowish encrustation in the nose?—Not necessarily.

Does it sometimes?—It might upon rare occasions; I cannot say I have been struck by it.

Now would you mind answering my Lord's question, and tell us what, in your opinion, are the symptoms of diphtheria?—The spread of a membrane over the uvula and soft palate, the cervical glands, that is the glands at the angles of the jaw, very much enlarged so that the jaw becomes practically square, there is not a very high temperature; the pulse is not very much above normal. The mucous membrane surrounding the membrane is of a pallid colour usually. Only one tonsil is affected, and the ulceration which occurs is usually afterwards covered by a membrane. I think those are the main symptoms and physical signs.

Mr. JUSTICE LUSH. Did you observe any of those symptoms on one of the days on which you attended this child?—No.

Not one?—Not one.

Not even on the 9th of August?—No. On the 9th of August the throat was perfectly clear.

Mr. VACHELL. As to those symptoms that you have named, are those only to be found in very severe cases that have been in existence for some time?—No, those are the signs, the pathognomonic signs.

In the first three days of an attack of diphtheria would you expect to find the glands swollen to the extent you have put?—That is one of the very earliest signs of diphtheria.

The jaw swollen to the extent of making the face appear almost square?—That will come on within two or three days.

You have heard Sir William Willcox give us his evidence upon this point?—Yes.

And you have heard him say that in many cases the glands are swollen to so slight an extent that it is only by palpation that you can discover it?—I do not accept Sir William Willcox's statement at all on that point.

Do you agree that with the swelling of the glands to the extent you have described, those cases are nearly always fatal?—Certainly not. I can remember now about 30 years ago a number of cases that I attended in which the whole of those symptoms were present. I can mention the name of the physician under whose care they were at the time, and whom I assisted, Dr. Shingleton Smith, of Bristol, and every one of those cases recovered, and no antitoxin was used throughout.

How many years ago would that be?—That would be, roughly, 30 years ago. It was when I was at the Bristol Royal Infirmary.

As a student?—I was in my last year.

Anything since then?—I have had a fair number of cases since then.

Mr. JUSTICE LUSH. About how many?—I saw a great many when I was in practice in Somerset.

How long ago was that?—That was, I should think, roughly, 32 years ago.

Let us come down to more recent times; take the last 10 or 15 years. How many cases of diphtheria?—I have had very few indeed of late years. There is not much genuine diphtheria about.

If you have had very few how have you been able to form an opinion as to the utility or otherwise of antitoxin?—I judge the utility of antitoxin, as in the case of any other remedy—namely, in the language of statistics.

Then you rely only on statistics practically ?—It is the only thing you can rely upon.

" I rely on statistics in support of my view as to antitoxin being a dangerous and useless remedy " ; is that right ?—Exactly.

Mr. Vachell. Do you agree that the very large majority of the members of the medical profession are in high favour of the utility of antitoxin ?—I do.

Mr. Justice Lush. You know they are ?—Yes.

Mr. Vachell. And that majority includes some of the most learned and reputed and skilful members of the profession ?—I quite agree.

Mr. Justice Lush. That is rather a responsibility, is it not ? If the majority of members, including the most eminent, are in favour of antitoxin, and if the Registrar-General's returns are as we know they are, and you have had very few cases, is not it rather a responsibility on your part to say you will not use it ?—The whole medical profession at one time were unanimously in favour of bleeding.

Never mind that, that is another matter ; cannot you deal with antitoxin ?—I judge a question, and I use my own intellect in order to judge whether I consider a case to be right or wrong, and I act accordingly.

But your intellect must work upon some materials ?—Certainly.

And you told us the statistics are what you work on ?—Yes.

They show that antitoxin is a most useful remedy ?—No, I do not agree ; I consider they show that they justify my view.

I should like to see some indication of it ; there is nothing I heard of yesterday in the statistics to show it is a dangerous remedy, is there ?—I will take the Registrar-General's returns, which I consider the scientific ground for statistical judgment.

Mr. Vachell. But you told me just now that you heard yesterday those figures given to the Court, that in 1893, which is just about a year, I think, or two years before antitoxin began to be used, the death-rate per million was 387. Then antitoxin came into use two years after, and by 1923 the death-rate had been reduced to 71 per million, and you accepted that.

Mr. Justice Lush. You accepted that ?—I certainly commented on it, but the learned Counsel took no notice of my answer.

What was that ; will you repeat it ?—That they were single years. There are such things as epidemics of diphtheria, and they vary. Sometimes there is a tremendous outbreak of diphtheria, and another time there is very little.

You have not dealt with my question. I wish you would repeat it for me ; I will put it again myself. What is there in the statistics to lead you to the conclusion that it is a dangerous and useless remedy ; that is what I want you to deal with ?—Allow me to turn to the Registrar-General's returns.

Yes, let me see what there is to justify that view ?—I will take the Registrar-General's returns on page 35. That is only just published within the last month. In the years 1871 to 1875, that is 25 years before antitoxin was introduced, the death-rate was 121 per million.

Mr. Vachell. Will you just stop there. You have gone back to an early date. Was that before the bacillus was discovered ?—The bacillus was discovered in 1883.

Mr. Justice Lush. The first time that the serum was prepared and cultivated and used was, I think, 1895 ?—That is so.

Mr. Vachell. This was the discovery of the bacillus ?

Mr. Justice Lush. That precedes the use of the serum.

Mr. Vachell. Yes ?—I go back to the date before the bacillus was discovered, or before antitoxin came in, that is the quinquennial years 1871 to 1875. Now I take the last quinquennial which the Registrar-General gives—namely, 1916 to 1920, and the death to the living population has risen in that quinquennium from 121 per million to 142 per million, that is, that it is 21 per million more than it was in 1871 to 1875.

Mr. Justice Lush. The death-rate from what ?—From diphtheria.

Mr. Vachell. Before the discovery of the bacillus, was croup treated separately from diphtheria ?—Croup was.

And you have excluded croup, have you not ? It is not included in those figures of diphtheria you have been giving us ?—All membranous croup is now included in diphtheria.

Mr. Justice Lush. Take your early date. If croup was treated separately you must add your death-rate for croup to diphtheria in order to bring it on the same line as the present figure. Will you do that for us. Add the death-rate for croup ?—He does not give it.

Let us have that figure. It is useless to compare one thing with two, which is what you have done ?—The diphtheria and croup together are 305 in 1871 to 1875, and in 1916 to 1920 it is 143.

Therefore instead of being what you say, a rise in the death-rate, it is about half what the death-rate was. Just look at that for yourself. If you take diphtheria and croup together, which is the way it is treated now, you find, do you not, that the death-rate instead of increasing has fallen from 305 to 143. Is not that so ?—That is so, undoubtedly.

Why do you compare the wrong thing. Why do you compare one thing only in 1875 with two things in 1916 ?—Because the Registrar-General separates them himself. He gives the diphtheria by itself and the diphtheria and croup by themselves. I was going on a wrong argument. Have you my pamphlet there ?

Before you turn to your pamphlet do clear up this point ; it is a perfectly simple equation. If you take from your statistics diphtheria and croup in 1875, and you take diphtheria and croup in 1916, then you find instead of the death-rate increasing it has fallen from over 300 to 142 ?

Sir Edward Marshall Hall. On the assumption that croup is diphtheria.

Mr. Justice Lush. They are grouped together, you see. He is working on statistics. Is not that right ?—Yes.

Mr. Vachell. He takes it at one end and not the other.

Mr. Justice Lush. If that is right how do you justify your statement that the statistics show that this treatment is useless and dangerous ?—Because this is the question of croup being thrown in with the diphtheria. In the early days, and in the last stage, the last quinquennium, the croup is now practically not recognised in relation to diphtheria at all.

Mr. Vachell. Is it called membranous croup ?—Called membranous croup.

Is it the same bacillus as diphtheria ?—Well, of course.

Well, is it ?—I myself do not accept any bacillus as the origin of diphtheria at all.

Mr. Justice Lush. Why ; on what ground do you base that view ? Dr. Hadwen does not accept the bacillus theory with regard to diphtheria. On what do you base that view ? Is that the result of study ?—Undoubtedly. I look upon the bacillus as the result of disease and not its cause.

Mr. Vachell. You recognise the existence, of course, of the bacillus ?—Yes, certainly.

And I am not quite sure that you gave me an answer to this, namely, as to whether that bacillus is not the same in diphtheria as in croup ?—I expect it is the same. I expect it is found in the same connexion.

Did you base your objections to antitoxin on those figures that you have just been giving to my Lord ?—Yes, to a large extent.

Not, I take it, on the particular edition of statistics that you have before you ?—I follow the Registrar-General's statistics year by year.

And on the same basis that you have dealt with them before your attention was called to the error ?—Yes.

And on that basis was it that you refused in all cases to administer antitoxin, and made, indeed, a crusade against it ?—Largely upon the ground of statistics.

Mr. JUSTICE LUSH. Is there anything else ?—Certainly. Another reason is that I consider the injection of poisoned horse blood into a human system is not a scientific method of treatment.

Mr. VACHELL. But it is adopted by men with the highest knowledge of science, I think ?—Yes.

Whether the bacillus is the origin or the result, the evidence of the disease, I suppose its discovery in a case where a person is suffering from these symptoms, would make the matter beyond doubt that he was suffering from diphtheria ?—Certainly not. Loeffler himself, the discoverer of the bacillus, found the diphtheritic bacillus absent in 25 per cent. of the cases of genuine diphtheria.

But if you did find it. I am not saying you do not. Loeffler is not here, I suppose, is he ? He was a German scientist, was not he ?—Yes.

What I am putting to you is this : If you did find the bacillus in the throat of the person who was suffering from these symptoms you would know at once that they had diphtheria ?—Oh dear, no.

Not even then ?—No.

Mr. JUSTICE LUSH. What ?

Mr. VACHELL. If you found the bacillus in the throat of a person who was suffering from these symptoms.

Mr. JUSTICE LUSH. You said then you would not diagnose diphtheria ?—I should judge diphtheria by the clinical signs, and seeing that the diphtheria bacillus is absent in a large number of cases of genuine diphtheria, and that it is present, as Professor Osler says in his work, in every kind of sore-throat from a simple sore-throat to a septic angina, and that it can also be found in healthy throats, and, as one medical witness has said here, even in inanimate objects, I cannot possibly see what the diphtheritic bacillus has to do with the subject.

Come to it a little closer. I have mentioned certain symptoms to you, and I understood you to agree that they by themselves were indicative, we will call it, of diphtheria ?—Certainly.

If in addition to those symptoms you discovered the actual bacillus itself in the throat would you have any doubt that that is what diphtheria is ?—I should pay no attention whatever to the diphtheritic bacillus, because these bacilli are simply, judging by the great Professor Bachu, the normal constituents of the body which have been altered by reason of their morbid environment.

Then may I take it you would not take a swab ?—I would not ; I see no reason in it.

Would that apply to all diseases like typhoid fever and everything else, in your opinion ?—Yes.

Do you discard the whole of the bacillus theory ?—I discard the whole of the germ theory causing disease.

In all diseases ?—I believe it is an absolutely unscientific idea.

You think the whole of the medical profession practically have all gone wrong in attaching importance to the bacillus cultivation ?—I consider so.

You set up your judgment against them all ?

Mr. JUSTICE LUSH. All based on statistics and nothing else ?—No, I have already mentioned I consider it an unscientific method of treatment.

I do not at present understand that ; that is only a name you give it, unscientific ?—I have mentioned that to inject poisoned horse blood into a human body is to my mind contrary to even the dictates of nature.

Mr. JUSTICE LUSH. Now we know where we are at all events.

Sir EDWARD MARSHALL HALL. I would like to take your Lordship's ruling on this ; I have been loth to interfere in any way ; I do not want to, but does your Lordship think this cross-examination is relevant to this issue ?

Mr. JUSTICE LUSH. I quite agree with this, that I do not think in this case the Jury have to consider whether there was neglect or not in respect of the bacillus, because Dr. Hadwen's view is, and his contention was all through, that there was no diphtheria, and he had not to consider the antitoxin treatment.

Sir EDWARD MARSHALL HALL. I agree this might be most interesting if the inquiry is, is Dr. Hadwen right or wrong in his view.

Mr. JUSTICE LUSH. No, but I cannot shut it out because it is going to credit.

Sir EDWARD MARSHALL HALL. That I agree; that is why I did not intervene before. It also goes to something else ; it goes to prejudice.

Mr. JUSTICE LUSH. I cannot shut it out. Let me be clear ; I think this cross-examination is relevant because it goes to what one ordinarily calls the credit of the witness, I do not mean in respect of truthfulness but in respect of the care he takes in things he deals with, but in itself it is not to the issue.

Mr. VACHELL. It is no personal attack on Dr. Hadwen at all. (To the Witness.) May I take it that holding the views that you do you would consider it positively harmful to any patient of yours to be treated with antitoxin ?—I should.

As to the swab I will leave that ; I may take it you never have used the swab ?—I never have.

You have never submitted one to a bacteriological examination ?—Never.

Do you agree with this, that the bacteriologist, at any rate, on examining the swab can detect the presence of the bacillus if it is there ?—Yes, I have many a time done it myself.

Leonard was the first of these children you dealt with ?—Yes.

You suspected it might be a case of diphtheria, I gather ?—Yes, I had it in my mind.

You have heard what the mother has said about the symptoms ; you deny it. It is no use going over them one by one with you. You deny, I understand, that there were any of those symptoms in Leonard's case ?—I saw nothing of them at all.

Nothing of the symptoms ; I do not mean the conclusion ?—No, the symptoms.

No discharge and no odour ; neither of those ?—No.

You heard the mother say that at one date in the illness—I think it was the 24th—what day were you called in ?—To whom ?

To Leonard ?—I cannot say whether it was the 21st I called first.

You heard her say that he spat up something which as she described it led one to believe it was membrane from the way she described it. You heard her say that ?—No.

In the witness box ?—With Leonard ?

Mr. JUSTICE LUSH. I am not aware of it.

Mr. VACHELL. I am very sorry. It was before the Coroner.

Sir EDWARD MARSHALL HALL. No. Please do not make these remarks.

Mr. VACHELL. I am going to withdraw it altogether if it was not said here.

Mr. JUSTICE LUSH. I do not think it was.

Sir EDWARD MARSHALL HALL. I am very confident about it myself ; I have no recollection of it, and apparently the Jury are of the same view.

Mr. JUSTICE LUSH. I am not aware of it.

Mr. VACHELL. I am very sorry that that should be so. One is usually misled by looking at the other examinations.

Mr. JUSTICE LUSH. Quite. I wish you would ask Dr. Hadwen to tell us again how often he attended Leonard. You went every day to him, did not you ?

Sir EDWARD MARSHALL HALL. He said five times.

Mr. JUSTICE LUSH. You attended on consecutive days ?—Yes, I did.

Mr. JUSTICE LUSH. Therefore as far as Leonard is concerned you cannot be said not to have given him enough attention in point of the number of visits.

Sir EDWARD MARSHALL HALL. Your Lordship will not forget yesterday that he said Leonard had the worst throat of the three.

Mr. JUSTICE LUSH. And he went to Leonard every day for three or four days.

Mr. VACHELL. Yes. Gladys was the next case. Did you see no signs in her case ?—None whatever. There was really very little the matter with her.

Did you in any way connect her illness with that of Leonard's ?—I presume that it was the same kind of throat. The septic tonsillitis runs right through a family, generally speaking.

Whatever it was, it was something that was infectious, is that it ?—It depends what you call infectious. I think the condition of the house was such as would be very likely to produce an atmospheric state calculated to result in tonsillitis.

Then you have the little girl who died, Nellie ; she was taken ill in the same way ?—Yes.

Did you connect her illness with that of her brother and sister ?—Yes.

By infection ?—Yes ; I do not mean from one person to another, but the atmospheric condition.

Would that be because the bacillus had passed from one of the other two children to her ?—Oh dear no ; as I have already said, I do not believe in the bacillus ; I believe that these result from a chemical poison, an atmospheric chemical poison.

You do not think, then, that disease is capable of being communicated from one person to another by bacillus ?—Not by the bacillus, but it can be communicated in many cases—small-pox, for instance, is very infectious.

We had better not, I think, talk about small-pox ; let us deal with diphtheria. In that case do you think that the disease was communicated from one to another by bacillus ?—No, I do not.

Mr. Justice Lush. What is your theory as to communication, then ?—An atmospheric condition.

Mr. Vachell. That is consistent with the bacilli being in the atmosphere, is not it ?—No bacillus has ever yet been collected from the atmosphere, cultivated, and injected into a human being, and produced the disease with which that specific bacillus is supposed to be the cause. Pasteur was challenged again and again to do that, and he never did it.

That means no, does it, in answer to my Lord's question that you do not think it is the bacillus in the atmosphere ?—No, I believe it is the chemical poison.

The atmosphere without the bacillus, is it ?—Yes.

It is a chemical poison ?—There is no proof that the bacillus exists in the atmosphere.

Has any disease ever been traced by the analyst to a chemical origin in the atmosphere ?—That is a mystery that no one has ever yet been able to discover.

I only want to know, has it ever been traced to a chemical origin ?—No, because you cannot discover in the atmosphere any specific chemical cause for it.

So you put it down to something in the atmosphere ?—We only know that insanitary conditions produce it.

In your view would it be perfectly safe, then, to transplant a bacillus, or bacilli, of diphtheria from a person suffering from diphtheria into a healthy throat ?—To transplant ?

Yes, to transfer ?

Mr. Justice Lush. Take a patch with bacilli upon it, and put it into the healthy child's throat ; would you like to be the child, or would not you mind ?—If it were the bacillus itself I should not hesitate, separated from its surrounding parts, I should not hesitate at all about that bacillus being put into a healthy person ; it would have no effect.

Mr. Vachell. Because you can get the bacillus with healthy surroundings, cannot you, from a culture ?—You can get the bacillus in all manner of healthy throats.

I mean if you wanted to get a bacillus, pure and simple, without any surroundings that would be of danger, you can do it ; you can get them ?—It is very difficult ; they are microscopic.

You say there would be no danger at all in having those placed in the throat of a healthy person ?—There is no proof that a specific bacillus has ever caused a specific disease.

When you saw Nellie was she suffering in the same way as her brother and sister ? —Yes, just the same.

When you saw her on the 1st of August did diphtheria cross you mind then ?—One always keeps it in mind, as far as that goes.

Did it ?—Of course it did.

You, of course, realised at that time if you took a swab you could get it examined bacteriologically by Dr. Washbourn, the official bacteriologist, who lives in the same City ?—Yes.

Did you know that would be about the first step that the ordinary medical man would take in such a case as this ?—It is the first step, I believe, that most medical men do take.

Mr. Justice Lush. I do not quite follow that. A medical man, if he only examines a throat, and finds it merely inflamed and red, with no indicative symptoms of diphtheria does not take a swab ?

Mr. Vachell. That is the question I put. I put to him that he found the little girl in a certain condition ; diphtheria was in his mind, and he agrees with me, in those circumstances, the ordinary medical man would take a swab ?

Mr. Justice Lush. Is that what you mean ? It is the fashion to take a swab in the case of practically every sore-throat to-day, and the result is that the vast number of simple sore-throats are now called diphtheria because they find diphtheria.

Do you mean whenever a child, or grown up person, has a sore-throat, the doctor always takes a swab ? That has become the fashion.

Mr. Justice Lush. That was not my view ; I thought it was only where there were some symptoms which would lead a doctor to suspect it might be serious.

Mr. Vachell. Your Lordship remembers this part of his answer, that diphtheria was in his mind.

Mr. Justice Lush. He said it is always in his mind. —Whenever there is a sore-throat one naturally thinks of diphtheria.

Did you see nothing to indicate in that child Nellie on the 1st August that the throat might be something more than an ordinary sore-throat ?—I saw nothing whatever.

Mr. Justice Lush. Because that, to my mind, is one of the most important questions in this case.

Sir Edward Marshall Hall. That is the crux of the case, I believe.

Mr. Justice Lush. The doctor did not go again for three days, and one must know whether he saw anything in the child's throat on the 1st of August to indicate that it was a case requiring real care.

Mr. Vachell. If your Lordship pleases. (To the Witness). You examined the child's throat, did you ? —Yes.

By putting your finger into the mouth to depress the tongue ?—No. I explained yesterday that in nine cases out of ten you can see a throat perfectly clearly by telling a child to open its mouth, breathe in, and say " Ah," and the uvula and soft palate rise up, and you get a full view of the whole thing. You only need to put the tip of your finger on the tongue to press the tongue slightly down.

You do not depress the tongue at the tip, do you ? It is not there you put your finger. You have to put your finger in some way ?—In nine cases out of ten you have no need to put your finger in at all.

That, apparently, is what you think is the best way ? —I do.

Do you agree that the usual way is to ask for a spoon ?—Yes, I think most people do, but, as I said yesterday, I consider the finger is the best tongue depressor you can have. Children are frightened of instruments.

Do you say you can see the tonsils by using your finger as a depressor ?—Yes.

You cannot see them until you depress the tongue, can you ?—Oh dear yes, in the majority of cases I never have to use my finger at all. It is a pure knack.

Did you use your finger in looking at the throats of two of the other children ?—I cannot say ; I may have done.

Mr. Justice Lush. What about Leonard ; did you treat him as you did Nellie ?—Exactly the same.

Mr. VACHELL. If this had been diphtheria what would your treatment have been ?—I should have put hot fomentations round the throat, and have painted the tonsils with glycerine three or four times a day.

Mr. JUSTICE LUSH. Is that an antiseptic, or has it antiseptic qualities ?—It is partly an antiseptic ; it is hygroscopic, that is, it draws the water, the fluid, out from the mucous membrane, and permeates the whole of the mucous membrane. Glycerine is one of the most valuable remedies for application in the Pharmacopœia.

Mr. VACHELL. Would you have cautioned the mother that the child must be kept in a recumbent position ?—I should.

Would you have made frequent attendances on the child ?—I should have called at least once a day.

You would not, I take it, have notified the authorities, would you ?—Had it been diphtheria I should, of course.

And would you have advised the removal of the child to the Isolation Hospital ?—I should, under these circumstances.

Mr. JUSTICE LUSH. You did not notify Leonard's case, of course ?—No.

Mr. VACHELL. None of these things, of course, were done by you in this case ?—No, of course not.

In fact you did not treat it as diphtheria at all ?—No.

Sir EDWARD MARSHALL HALL. That is admitted.

Mr. VACHELL. She is quite a respectable woman, the mother, Mrs. Burnham, is not she ?—Quite.

And evidently regarded you as the medical man of her choice ?—I have always got on with her exceedingly well, and she has got on exceedingly well with me.

And she has no animus against you ?—I do not see what grounds she has for it.

Do you know Mrs. Taylor at all ?—No.

Or did you know Mrs. Peachey ?—No.

Or the brother-in-law ?—No. I know nothing about them.

They none of them, at any rate, have any ground for hostility to you ?—Not that I know of.

And they are respectable people ?—Yes.

You have heard from all those four people statements as to the different symptoms they observed during the child's illness. Do you say they are all mistaken ?—I am afraid I must say that they are. I cannot understand it.

You have heard as to the smell that on the occasion that the little child went down for the drink of water on the 7th the mother had actually gone out for a disinfectant because the smell from the child was so bad. Did you observe nothing of such a smell ?—Nothing whatever.

Not at any time ?—Not at any time.

You have heard the mother say she drew your attention to membrane formed coming from the nose ; is that untrue ?—That she stated on the last occasion. She did not mention that on the two previous occasions.

What do you say to it ?—I never saw anything of the kind.

Was the child drowsy when you were there ?—No.

Not at any time ?—Not at any time.

Mr. JUSTICE LUSH. Not on the 9th ?—Yes, on the 9th the poor little thing was absolutely ill.

You must eliminate that ?—Yes.

Mr. VACHELL. On the 6th you say the child was sitting up and smiling ?—Yes.

Nothing the matter with her, practically ?—No, except exceedingly weak, a poor ill-conditioned child.

Do you accept it that the child died of diphtheria ?—Certainly not.

Mr. JUSTICE LUSH. You say you do not now agree ?—Oh dear no. I was quite sure the child never had diphtheria, and never had a symptom of it.

Mr. VACHELL. You do not agree, then, that she died of it ?—Certainly not.

Do you accept it that the other children, Gladys and Hilda, whom you never attended I know, and the little playmate, Olive Cornock, had it ?—I know nothing about those children.

I will leave out Hilda and the other, but do you agree that Gladys was suffering from diphtheria ?—Oh dear no, it was simply the septic tonsillitis which ran, as it does run, through a house.

Mr. JUSTICE LUSH. I do not follow that, if I might interpose with a question. Have you heard Dr. Washbourn give us the result of his post-mortem examination ?—Yes.

And he described the membrane he found, and things that you yourself say would be symptomatic of diphtheria ?—No, there was no membrane found in the throat at the post-mortem examination.

Mr. VACHELL. Yes.

Sir EDWARD MARSHALL HALL. No ?—None whatever.

Mr. VACHELL. First of all, on the last day the 9th ?

Sir EDWARD MARSHALL HALL. Do not let my friend pass away from it. My friend is contradicting this answer, and he says he has evidence that there was diphtheritic membrane found in the throat. I challenged that, and Sir William Willcox accepted that. It was in the lung.

Mr. JUSTICE LUSH. I thought Dr. Washbourn gave one of his reasons for saying it was a diphtheritic membrane.

Mr. VACHELL. A loose piece of membrane which had escaped, indicating where it had come from, and it was on the top of the lung.

Sir EDWARD MARSHALL HALL. It was not found in the throat.

Mr. JUSTICE LUSH. No, but it had been somewhere in the child's mouth.

Mr. VACHELL. It was in the lung ?—Not necessarily.

Mr. VACHELL. Dr. Washbourn said he found these raw, I think was the term used, patches in the throat, from whence it had come.

Mr. JUSTICE LUSH. That is what I meant, and what I thought I said.

Sir EDWARD MARSHALL HALL. I do not say my friend is deliberately evading the point, but my learned friend said that Dr. Washbourn said that this membrane was found by him, post mortem, in the throat. I say Dr. Washbourn never said anything of the kind. What he did say was : "I found membrane I believe to be diphtheritic. I found a place in the throat which was raw, and I drew the conclusion that that membrane I found in the lung had come away from the sore place in the throat."

Mr. VACHELL. My friend's witness does not require all this assistance, at least, I think not. What I have said is exactly that ; I have not misrepresented Dr. Washbourn's evidence. Your Lordship has repeated it, and I am exactly with it. There was this, in addition, that he also found the vessel, the bronchus of the right lung, thickly coated with diphtheritic membrane, some of which had grown in situ.

Mr. JUSTICE LUSH. Accepting those as facts, assuming that Dr. Washbourn is right in what he said he saw, and coupling them with the fact that when the swab was bacteriologically examined the diphtheria microbe was found, would that not persuade you that it was, at all events, in all probability a case of diphtheria ?—No, my Lord. The point is this. He found some membrane in the bronchus. That membrane he said he believed to be diphtheritic. He never examined that microscopically, and therefore he can produce no proof, and no authority, that it was diphtheritic. Further, it is quite a common thing, when a child has croupous pneumonia it must be remembered that lobar and croupous pneumonia are the same thing, and the words croupous pneumonia are given to lobar pneumonia because it is accompanied by a membranous exudation which is so like croup that you cannot distinguish it, and this membrane, both in the larynx, on the back of the œsophagus and in the bronchus, might all have been the result of an ordinary inflammation, spreading up from the croupous pneumonia which had affected the lung.

Mr. VACHELL. Dr. Washbourn has had some experience ; do you agree with that ?—Certainly, very large experience.

He has been a bacteriologist for some time ?—Yes.

How long ?—I cannot say.

Quite a long time ?—Yes.

And he is regarded as a very honourable and upright gentleman ?—I have every respect for Dr. Washbourn.

Do you say that Dr. Washbourn, then, has made a mistake about this membrane ?—It is not a question of making a mistake ; it is a question that he gives as his opinion that this was diphtheritic membrane for which I say he has no authority.

Did you ever see it ?—No, unfortunately, I did not. I ought to have seen it.

He did ?—He did.

Do you set up your opinion against his ?—I set up my opinion, because it is not a question of opinion against his opinion. I say he has never proved that it was diphtheritic. He had no microscopic examination.

What about the growth in the bronchus ?—It was pneumonic, croupous pneumonic.

The membrane he saw there ?—That membrane was, of course, the result of the croupous pneumonia.

Is diphtheritic membrane quite easy to identify ?—Yes, I agree.

And you have heard Dr. Washbourn who, I take it, is a careful gentleman ?—Certainly.

You have heard him say that that membrane in the bronchus tube was diphtheritic ; what do you say to that ?—I again say he has no authority for saying so, he never examined it microscopically. Sir William Willcox himself said in the witness box before the Magistrates that he had not done that, and therefore he could not definitely prove that it was diphtheritic.

Mr. JUSTICE LUSH. What does the microscope reveal when you examine the membrane ?—It reveals the bacillus which is supposed to be associated with diphtheria or pneumonia, whatever it may be, and therefore gives to it its name.

Then you do attach importance to the fact of whether the bacillus is, or is not, in the membrane ?—No, I am simply arguing from their standpoint.

No, let us keep to the point, if you do not mind. I asked what good a microscope would do, and I thought you said it would reveal the presence of the bacillus there. Did not you say that ?—I did.

But a short time ago, when you were asked about this bacillus, and the advantage of taking a swab, you said it did not matter whether the thing was examined or not, because the presence of the diphtheria bacillus would not show it was diphtheria?—You misunderstood me.

I wish you would make me understand ?—Whether a thing is diphtheritic or not according to the recognised fashion of the time, it must be associated with a certain germ. These membranes are all practically alike, and it is impossible, from naked-eye appearance, to judge whether it is diphtheritic, pneumococcic, or any other kind of membrane ; you must examine it by the microscope to discover. Osler gives two pages to diphtheroid membrane, that is membrane in which you cannot tell the difference between diphtheria and the other membrane unless you examine them microscopically, and he never did that.

Mr. VACHELL. You spoke about what Sir William Willcox told us, or what you say he said before the Magistrates ?—Yes.

Do you know that what he said as to microscopical examination referred to fatty degeneration of the heart, and not to membrane ? Will you find the passage ? I challenge my learned friend to find that passage.

Sir EDWARD MARSHALL HALL. What he said is within my recollection. He said : " I had no need to examine it microscopically, because I could tell it from the view, I was so certain."

Mr. VACHELL. That is not what the Doctor has tried to put upon us, but that Sir William Willcox admitted before the Coroner that you could not identify the diphtheria membrane without a microscope.

Mr. JUSTICE LUSH. That is what he said ; let us see if that is right.

Sir EDWARD MARSHALL HALL. It was not before the Coroner ; he did not appear there.

Mr. VACHELL. It was before the Magistrates.

Sir EDWARD MARSHALL HALL. I can find that Dr. Washbourn said it before the Coroner. He said : " It is necessary to have a microscopic examination to decide between them," that is the condition of the pneumonia. " I made no microscopic examination."

Mr. VACHELL. Of the pneumonia ?

Sir EDWARD MARSHALL HALL. Of the lung.

Mr. VACHELL. The point I put is the membrane ; this piece of loose membrane he found.

Sir EDWARD MARSHALL HALL. That was found in the lung.—I did not understand you were referring to the bit of loose membrane ; I understood you were referring to the membrane that choked the bronchial tubes.

Mr. VACHELL. First of all as to the loose membrane what do you say as to that ?—My own opinion is that the loose membrane was coughed off from the lung itself.

The question is, would Dr. Washbourn, in your opinion, be able to identify that ? He said that that was diphtheria membrane.—He had no right to call it diphtheria membrane if he did not examine it microscopically.

Then you say that without a microscopic examination he could not identify it ?—No, he could not.

Has he ever said that himself ?—I do not remember. No, I do not think he has.

Has Dr. William Willcox ever said it ?—Sir William Willcox stated definitely that Dr. Washbourn had not thoroughly conducted this post-mortem examination. If I have the paper I can find it.

Will you answer the question ? Has Sir William Willcox ever said that Dr. Washbourn could not identify the loose piece of membrane ?—I do not know that any reference was given to that at all.

As a matter of fact have they not both said that it could be identified, and easily ?—I do not know ; I do not remember that. All I can say is that it cannot.

As to where it came from, you say it would be coughed up ?—It may.

Would there be some raw spot from whence it had come ?—No, I think it is not at all unlikely, when Dr. Ellis punctured the lung, that he set loose a portion —he went into a bronchus, and set loose a portion of the exudation—and that was the reason why it set up a reflex cough, and brought it on ; that is my theory.

As to the bronchial tube, where it was found actually growing, what is your view as to that ?—That, of course, was part of the pneumonia affection.

Dr. Washbourn has told us that that was diphtheria membrane ?—I say he has no authority for saying so.

Do you say that Dr. Washbourn is mistaken again about the membrane in the bronchial tube ?—I do not understand your question.

What I want to know is this : We have had here a well-known Doctor who, for some years, has been the bacteriological examiner. He tells us positively that he found diphtheria membrane growing in the large bronchial tube of the right lung ?—But, as I have already said, he never bacteriologically examined it.

Mr. JUSTICE LUSH. We shall not get much further with it.

Mr. VACHELL. No, I am afraid not. (To the Witness.) Then you believe in bacteriological examinations for one thing, but not for another ?—No, I do not believe in it at all.

You heard Dr. Washbourn say that he also found certain raw patches in the throat from which, in his opinion, that loose piece of membrane had probably come ?—He made use of that expression for the first time in this Court.

He said it ?—He said it, but in his official report, and in the statements he made previously, he never used that word " raw " at all.

You mean, then, we are to disagree with him, that he did not find anything of the sort ?

Sir EDWARD MARSHALL HALL. He said raw.

Mr. VACHELL. Inflamed and raw. It is the difference between inflamed surface and raw.

And of such a character that he said that, in his judgment, the loose piece had come from it; what do you say as to that?—He has no authority for saying so.

Was it there?—How could it have been there?

Were the patches there?—There was no membrane in that throat when I saw it by daylight on Saturday morning, and there could have been no membrane in that throat on Saturday night, and if there was that membrane on Saturday night it ought to have been at the post-mortem, and there was none.

It is not said that the membrane could be seen from the outside. The membrane he was speaking of was out of sight, but in this large bronchial tube?—Very well, then I say that was a continuation from the croupous pneumonia, and had nothing to do with diphtheria.

He also said that there were patches in the throat from which he thought the loose piece had come which could be seen from the mouth; what do you say as to that?—He used that word "raw" upon this occasion. I say he had no authority for doing so. He simply said it was red and inflamed.

Red and inflamed; what do you say as to that?—I say he has no right to say that the membrane came from there.

As to the existence of the patches, what do you say?—That is something he has added since, and has nothing to do with what he said previously.

Then you mean we are not to believe him?—I think he has rather gone upon his imagination, to some extent. I do not want to say anything with regard to Dr. Washbourn. I thoroughly respect him, and I do not want to be made to say that what he said was untrue.

I do not want you to say anything, but I would like to know this, whether you deny that there were these inflamed patches in the throat?—I accept the statement that there were inflamed patches. He said so at the onset, and I quite accept the statement.

Did you see those yourself?—How could I see them when I was not allowed to be at the post-mortem examination?

On the Saturday night, when the child was alive?—I was not there on the Saturday night.

On the Saturday morning?—On the Saturday morning the throat was inflamed and red, much about the same as Dr. Washbourn has described at the post-mortem examination, but there was no membrane there.

But it was inflamed and red?—Certainly.

I thought it had all cleared up by the Wednesday?—Of course the ulceration had gone from the tonsils, but there never was any membrane on the uvula, or soft palate, and the fact of it being red and inflamed, not only as I saw it, but as Dr. Washbourn saw it at the post-mortem examination, proves conclusively that it was not diphtheria.

Mr. JUSTICE LUSH. There must be no demonstration in Court. I am surprised that in a case of this kind people should give way to their emotions when an answer is given. (To the Witness.) Are you not influenced in your view about the existence of diphtheria by the views you hold of the part the bacillus plays in the disease?—I really think, as the result of a long experience, and a very careful attention to all great questions of the day, that I am capable of forming an impartial judgment absolutely free from bias of every description upon a vital matter of this sort.

Are you not desirous of constantly learning from statistics?—I am always trying.

Wait one moment—and the experience of other doctors, especially those who have given themselves up to the study of bacteriology? Are you not desirous of always learning, and seeing whether you cannot get more knowledge than you had before?—Most decidedly I am, but I look upon the whole of this Pasteur theory as a retrograde movement; it is going back, not going forward.

I wish I could see some justification for that view; I cannot find any. When you are asked why you hold these views you fall back upon statistics. Then you make a mistake, as has been pointed out; you have compared two wrong figures. If that has gone, what is left which forms the basis of this strong view you hold? If you eliminate statistics what else do you rely upon, justifying your differing from practically the whole of the medical profession?—The basis of the whole theory is that a specific germ is the cause of the specific disease, and I maintain that those who hold this view have never yet proved it. Prof. Koch wrote to Pasteur, and said: "If that theory is correct the germ must be found in connexion with every specific disease; it must not be absent from that disease; thirdly, that it must be cultivated apart from the disease, and lastly, that when the culture is inoculated into a human body it must produce that identical disease." Pasteur accepted that theory, and, as far as I know, it has not yet proved to be true. The Editor of THE LANCET himself has declared that, based on Koch's postulates, the whole germ theory falls to the ground.

Mr. JUSTICE LUSH. My question was not quite that which Dr. Hadwen answered. I asked him a simple question whether he did not think he was influenced in his view about the presence of diphtheria by the strong view he took about the bacillus. I did not invite that long explanation.

Mr. VACHELL. No. My learned friend seems to think I have.

Sir EDWARD MARSHALL HALL. I was dealing with the whole line of this cross-examination. My friend knew before we came into Court that Dr. Hadwen holds extreme views on this subject. If you cross-examine him in this way, and he is honest, you must expect him to rather flare up.

Mr. JUSTICE LUSH. One of the questions the Jury must consider is whether there was diphtheria in this child.

Sir EDWARD MARSHALL HALL. If your Lordship so directs them of course I cannot prevent it, but I think it is entirely immaterial in this case on a charge of manslaughter.

Mr. JUSTICE LUSH. You must give me credit for not forgetting that I told you frankly I shall tell the Jury—it is entirely for them—that even if they think there was gross neglect or culpable negligence that that does not of course dispose of the case at all. They will have to find that even on the hypothesis that there was gross neglect, and on the hypothesis that there was diphtheria, that Dr. Hadwen caused the death of that child or accelerated it before they convict him.

Sir EDWARD MARSHALL HALL. I agree. I was going further than that. I knew your Lordship was going to say that. I shall contend, when your Lordship gives me an opportunity of stating what I contend, that even if in fact this child had diphtheria that is really not relevant except for the purpose of deciding whether there was gross neglect or not.

Mr. JUSTICE LUSH. That may be so, but I cannot shut it out upon that question. That is the only way in which it is material.

Sir EDWARD MARSHALL HALL. Does your Lordship propose to ask specific questions of the Jury?

Mr. JUSTICE LUSH. No, not at all, but I shall tell them they will have to find two things before they can convict upon this indictment, first that there was culpable, wicked, criminal neglect, whatever your expression may be, and secondly, and this is vital to the case, that that neglect if they find it existed did cause or accelerate the death of this child. Unless the Jury find both against Dr. Hadwen they must acquit him.

Sir EDWARD MARSHALL HALL. That raises the important question on the first part of your Lordship's judgment. Will your Lordship direct the Jury in order to constitute wilful or gross neglect of the kind your Lordship indicates, that it must be actually wilful and gross neglect, and I submit this cross-examination is proving it does not exist in this case, because if it was a neglect, and because if it was wilful, it was based upon a conviction that this child was not suffering from diphtheria. That is the dilemma my learned friend is in.

Mr. Justice Lush. I do not want to go into it at this stage. I cannot help saying on that that the mere fact that the Doctor holds a strong view does not in my opinion shut out the possibility of a Jury saying he was guilty of gross neglect. I am not saying it is so at all in Dr. Hadwen's case; I am only saying it generally, that a man may allow his mind to be in such a condition of prejudice that he may not in the opinion of the Jury be acting bona fide though he thought he was.

Sir Edward Marshall Hall. Is not that a case for a mental expert ?

Mr. Justice Lush. I do not know what you mean.

Sir Edward Marshall Hall. If a man has allowed his mind to get into such a state that because he holds an opinion so strongly that it is not reasonable, would he be responsible in law for the crime of manslaughter ?

Mr. Justice Lush. You do not say he is insane.

Sir Edward Marshall Hall. I am not suggesting that defence for a moment; it is only academic.

Mr. Justice Lush. We will not pursue it further, I must direct the Jury about it when the time comes. Please do not think I in the least degree suggested that you were too long, Mr. Vachell, I assure you that that was not in my mind.

Mr. Vachell. If your Lordship pleases. (To the Witness.) In addition to what we have been told of the post-mortem appearances, the swab proved to have bacillus on it. That does not affect your views at all ?—Not at all.

What do you say to the other children suffering from diphtheria ? You have heard Dr. Berry, from the Isolation Hospital, and we will take the case of one of them, if you like, Gladys.—Gladys was running about the streets when the child was taken to the hospital.

She was taken to the hospital and found to be suffering from diphtheria; what do you say to that ?—I cannot say. I understood from Dr. Berry that she had a sore nose.

Hilda, another sister, was living in the house and she was taken to the hospital and found to be suffering from diphtheria; what do you say to that ?—I expect it was the same kind of throat as the other.

In other words it was not diphtheria; is that it ? —I know nothing about it.

Assume that Dr. Berry was right and that they were so suffering, does that to your mind point to the probability of Nellie suffering from diphtheria as well ?—I do not think that is a fair question to ask me; unless I saw the patient I cannot form any judgment with regard to it.

I think it is a question you might answer. If you find a little girl very ill, who afterwards dies and the doctor finds the diphtheria bacillus in a swab taken in lifetime, that it was in her throat, and they find these post-mortem appearances and the doctors tell us she had diphtheria. Then you find from the same household about the same time two of the residents, two sisters of hers, are taken to the hospital and they are suffering from diphtheria, does that in your opinion make it more probable that Nellie's real disease was diphtheria too ?—Certainly not. Nellie had no symptoms of diphtheria whatever; neither had the boy whom I cured and Gladys I cured likewise.

I just want to remind you of what Dr. Ellis says he saw on the Saturday night, the 9th. He said he could see at that time membrane in the throat ? —Yes.

Do you accept that ?—No, I consider he was mistaken. What I expect he really saw was dried mucus and clotted milk which has been mistaken over and over again for diphtheritic membrane.

He also, I think, spoke of certain symptoms, did not he, the smell and the discharge ?—He said there was a discharge from the nose. All I have to say is there was none in the morning.

I am reminded that Dr. Ellis said he took a swab from the membrane ?—Not from the membrane; he took a swab from the throat.

If the membrane was there, that would be from the membrane, would it not ?—There was no membrane there; there could not have been.

If you have a case of diphtheria, do you tell the patient that there is a remedy that is generally in the profession looked upon as a good one, antitoxin, and give the patient the opportunity of having it administered ?—Certainly not. When a patient comes to me, a patient leaves himself in my hands and I treat him as I consider to be right.

And you would not take that step of giving him the opportunity of having the usual treatment prescribed ? —There is no necessity for it; I can cure diphtheria without.

Re-examined by Sir Edward Marshall Hall.

Does diphtheria always show itself first in the throat ? Can it originate in any other portion of the body ?—You can get membrane, what is called a diphtheritic membrane, in ulcers of all kinds everywhere.

Do you know of any case where it develops in the lung or in the bronchial tubes, for instance ?—I do not think so, I have never heard of anything of the kind.

You referred my friend, in vindication of your theory with regard to the want of value of the bacillus, to Osler's book which was referred to by my learned friend, and indeed by Sir William yesterday. Would you mind giving my Lord the exact passages out of this book which you were referring to ? Will you refer my Lord to the page, only on this one point of mistaken diagnosis of diphtheroids and diphtheria ? —It is at page 60. "Under the term diphtheroid may be grouped those membranous inflammations which are not associated with the Klebs-Loeffler bacillus. It is perhaps a more suitable designation than pseudo-diphtheria or secondary diphtheria. Streptococci and pneumococci are the organisms most often found. The name 'diphtheritis' is best used in an anatomical sense to designate an inflammation of a mucous membrane or integumentary surface characterised by necrosis and a fibrinous exudate, whereas the term 'diphtheria' should be limited to the disease caused by the Klebs-Loeffler bacillus. The proportion of cases of diphtheroid inflammation varies greatly in the different statistics." Then it gives a number of cases in which the diphtheroid affection occurs, scarlet fever, measles, whooping-cough, typhoid fever, and so on, right away on every kind of diphtheritic membrane which you cannot tell from diphtheria.

My friend has put to you a pamphlet which he suggests you wrote, from which he quoted, called "The Modern Medicine Man" and it is written by you. My friend has quoted a passage. Have you for a long time written a series of pamphlets against antitoxin and against all the serum treatment ? —I have.

1906 or 1909 somewhere about then was the latest, or have you written since then ?—I have written hundreds since then.

Anyhow in Gloucester have you published these pamphlets ?—Yes.

And my friend asked you what reason you had for being opposed to the administration of antitoxin and you answered him by saying that there was a well-known case of Prof. Langerhans and other cases, as to which you could not give the exact date. Do you know a book published by Dr. Bosanquet, a Fellow of the Royal College of Physicians, London, the Assistant Physician of the Charing Cross Hospital ? It is a book published by him on the serums, vaccines and toxins ?—Yes.

Mr. Justice Lush. What is the date of it ?

Sir Edward Marshall Hall. The 1909 edition. (To the Witness.) Is that a book you have frequently consulted ?—Yes, it is the standard work in the medical profession.

Sir Edward Marshall Hall. In view of the cross-examination I ask your Lordship that the Doctor may be allowed to cite the passage from that book.

The Witness. "It cannot be denied that in a certain number of instances the injection of diphtherial antitoxin has been followed by death, directly attributable to the action of the serum. A melancholy instance was afforded by the sudden death of Professor Langerhans' infant son soon after a prophylatic dose of the serum, but this has been attributed to the existence in the child of the status lymphaticus, which predisposes to death from trivial causes."

Mr. Justice Lush. This has been attributed to what?

Sir Edward Marshall Hall. To status lymphaticus. I will summarise it. If necessary, the passage can be found. I will not trouble you to read it in extenso. In that book are there recorded a number of deaths directly attributable to the injection of antitoxin?—Yes.

Mr. Vachell. I think it is a pity, when Sir William Willcox was in the box, that his attention was not drawn to it.

Mr. Justice Lush. I know. It is important.

Sir Edward Marshall Hall. My learned friend raised this point, I did not. I could not deal with it until my friend raised it; I was entirely unaware of it.

Mr. Justice Lush. It is enough for you to say, is not it, that in a well-recognised authority that statement is made by a person of some position. It may not be a correct view of the question upon an indictment for manslaughter. If the view is one that is entertained by reasonable people, whether it is right or wrong does not matter.

Mr. Vachell. It surely becomes important then that this should be dealt with a little more closely than that Dr. Hadwen should say, in a general way: "There are a number of fatal cases."

Mr. Justice Lush. Yes, we ought to know something more.

Mr. Vachell. Yes. The first one my friend read out from something referred to the fact that the child probably had status lymphaticus at the time.

Sir Edward Marshall Hall. I see that Sir William Willcox is still available, if any question arises on it.—May I be allowed to read from this standard work of Bosanquet and Eyre? It says: "It cannot be denied that in a certain number of instances the injection of diphtherial antitoxin has been followed by death, directly attributable to the action of the serum. A melancholy instance was afforded by the sudden death of Professor Langerhans' infant son soon after a prophylactic dose of the serum, but this has been attributed to the existence in the child of the status lymphaticus, which predisposes to death from trivial causes. A similar case of sudden death is recorded by Boone, in a boy aged 10 years, who after an injection of 4,000 units of antitoxin suddenly sat up, clutched at his throat, became deeply cyanosed, and died. No cause of death was discovered at the necropsy. Mackeen reports a fatality in a girl aged 17, the subject of asthma and status lymphaticus: in this case the antitoxin was administered as a prophylactic. Most of the fatal cases recorded have been of the same sudden character."

Mr. Justice Lush. I see one of the joint authors of that book is the bacteriologist at Guy's Hospital.—Yes.

Mr. Justice Lush. And bacteriologist to St. Mary's Children's Hospital.

Sir Edward Marshall Hall. And he is in charge of the vaccine department of Guy's. I hope your Lordship will realise that we are not advocating our personal views; we are dealing with Dr. Hadwen in this case.

Mr. Vachell. Did your Lordship follow that all that is from Bosanquet?

Sir Edward Marshall Hall. Yes.

Mr. Justice Lush. And Eyre.

Sir Edward Marshall Hall. Is that a recognised standard work?—It is.

In face of that, is it safe to say, as my learned friend suggested to you, that practically the whole of the medical profession are in favour of antitoxin treatment?—Quite true.

In spite of that, you venture to differ?—I do.

That is a matter you are responsible for, not me. With regard to those statistics, is there any difference between the total number of deaths and the case mortality from diphtheria; do you distinguish between the two?—Yes, most materially.

Will you try and explain to my Lord what it is in those statistics upon which you rely as supporting your theory of hostility to antitoxin treatment?—This is the Metropolitan Asylums Board Report, the last one published, and they base their statistics upon case mortality, that is the number of cases of notified diphtheria, and the number of deaths to the cases. What is noticeable here is this: The antitoxin treatment was introduced in the year 1895. With the introduction of the antitoxin treatment came an entirely new method of diagnosis. Instead of the diphtheria being diagnosed in the old-fashioned, and as I consider, scientific way of physical signs and symptoms, it became the fashion to diagnose it by a germ. The result was that a great many common sore-throats that would have got well under any circumstances were found, as Professor Osler and other writers admit, to have associated with them the diphtheria bacillus, and consequently they were called diphtheria. You can see that if you have an increased number of cases of common sore-throat thrown into the count the death-rate will decrease. It is a remarkable fact that with this new method of diagnosis the number of cases increased materially. You have it here that in 1895 there were only 3000 cases of diphtheria. In 1896 they had increased to 4000; in the next year the number of cases increased to 5000; in the next year they had increased to 6000; in the next year they had increased to 8000; and the more of these harmless bacteriological diphtheria cases that were thrown into the count the less was the death-rate. May I put it in this way? Supposing you had, say, 100 cases of diphtheria, and there were 21 deaths, that means a death-rate of 21 per cent. You add to that 100 cases 200 harmless cases of sore-throat with a germ with them which would not die at all, and then you have 300 cases, but the same number of deaths, and you have reduced your 21 per cent. down to 7 per cent. That is the statistical trick by which all these statistics are worked. And that applies to the very book which in this, and last year's edition, has admitted that there were over 2000 last year, and approximately 2000 this year, mistaken diagnoses of diphtheria which have been sent to fever hospitals in London alone.

Mr. Justice Lush. Then is it your view that a number of cases in which doctors say that the antitoxin treatment has been successful are really cases which are not diphtheritic at all?—That is so; it is a case of *post hoc ergo propter hoc.*

Sir Edward Marshall Hall. Has the existence of this Klebs-Loeffler bacillus, in cases which are not diphtheria, given rise to a certain name called Loeffleria, which is a book of 1923, a disease in which the bacillus is present without the ordinary symptoms?—Yes, and here I have a work by one of the chief medical men of the fever hospitals in London, in which he says that the cases of paralysis have increased materially since this has occurred: "The introduction of antitoxin treatment has had a marked effect upon the incidence of paralysis. On the whole, this has been increased probably because a large number of severe cases are tided over the acute stage of the attack, indeed this increased incidence has taken place in those brought under the treatment."

Mr. Justice Lush. If you look at Dr. Bosanquet's and Dr. Eyre's book I think you will find that statement explained and dealt with. He deals with that apparent increase of paralysis, and says, I think, there was nothing in it.

Sir Edward Marshall Hall. I purposely did not attach any importance to it, but the Doctor did.

Mr. Justice Lush. This is the passage, it is only fair to read it: "There is reason to believe that since the introduction of antitoxin the percentage of cases which suffer from paralysis after diphtheria has definitely increased. This effect was at first attributed to the remedy, and some prejudice against the use of it was thereby excited. Since, however, as we have just endeavoured to prove, it saves the lives of many patients who would otherwise have died "—that is rather praising the antitoxin.

Sir EDWARD MARSHALL HALL. It does.

Mr. JUSTICE LUSH. "And these severe cases are those which are most likely to exhibit paralysis later on, there inevitably arises an increase in the percentage of cases of paralysis: it is in reality a testimony to the value of the antitoxin, and not a drawback to its use."

Sir EDWARD MARSHALL HALL. What that means is that even if you give the patient paralysis it does not matter, because you have saved the life.

Mr. JUSTICE LUSH. It says the advantage is very great.

Sir EDWARD MARSHALL HALL. I am not suggesting that that book is against antitoxin, it is only recording some of the things that have happened.

Mr. JUSTICE LUSH. The book that Dr. Hadwen relies upon, under your re-examination, is rather condemnatory of his view.

Sir EDWARD MARSHALL HALL. (To the Witness.) Is the book an antitoxin book or not ?—No, this book is written by men who thoroughly believe in antitoxin, and yet they have to admit its failures, and the paralysis, and the rheumatism which it causes.

Sir EDWARD MARSHALL HALL. My friend asked you an important question about the presence of this exudation. You say there was no evidence of any exudation at all, and you gave your evidence of what you saw. Is Dr. Eyre a very well recognised authority ?—A standard writer.

I see on page 155 he says this, "Again in tonsillitis the exuda is seen on the tonsils only, whereas in diphtheria it is spread over the half arches of the uvula," and that is the distinction you draw in this case ?—That is the distinction.

If you have diagnosed this as diphtheria, you would, of course, have notified it and you yourself would have agreed to the child being removed. It was all to your advantage that the child should be removed because you were not paid by the visit, and you were paid the same whether the child was removed or not, so there was no reason why you should object to the removal ?—No.

You have heard my learned friend's cross-examination and the views which you have told my Lord you hold in answer to those questions. Are those honest views ?—Undoubtedly.

You do believe in them ?—I do.

And you rightly or wrongly think it would be against your conscience to use those methods which you do not approve of ?—Certainly.

Because, as you have told my Lord, rightly or wrongly, you believe they would do no good ?—That is so.

I will again repeat the question I asked you yesterday; did you ever diagnose diphtheria either in the case of Leonard or in the case of Nellie ?—I did not.

Was there any difference in the symptoms of Nellie and those of Leonard ?—None whatever.

Did you apply the same treatment in both cases ? I did.

Were they successful in the case of Leonard ?—Yes.

So far as Nellie is concerned, you told my learned friend you do not agree she died of diphtheria; you dispute it ?—Undoubtedly.

But what you do say is she died of pneumonia ?—Undoubtedly.

In your opinion was that a pneumonia consequent upon a chill which she contracted on that Thursday night ?—Yes.

Mr. JUSTICE LUSH. Especially with reference to the 1st August, a date which I may tell you I attach very great importance to, when you saw the child she was, of course, in bed ?—Yes.

Had she any temperature or do not you know ?—She had a temperature of 100°.

That was the time when you took the temperature ?—Yes.

And a pulse of a little above normal ?—Yes.

Had Leonard the same symptoms ?—Much about the same.

And was there any substantial difference between the throat of Nellie as you saw it then and the throat you had seen in Leonard's case ?—In Leonard's case the ulceration was very much worse.

Are you quite clear that on that date, 1st August, there was no discharge of a blood-stained yellow nature ?—I am absolutely positive.

When did you first hear it suggested that there was and that you ought to have seen it ?—The mother never mentioned a word of it to me at all. The first time I heard of it was at the inquiry, I forget now which inquiry, whether it was the first inquest or the adjourned inquest, but I never heard a word of it till then.

You did not go to the child again for three days ?—No.

You did go to Leonard every day ?—Yes.

Consecutive days ?—Because he was so much worse.

Leonard's case being so much worse, you did see him every day ?—Yes.

Nellie's throat not being so bad you did not think it necessary to go more times between that interval ?—I told the mother, "She will soon be all right; she has a cold and tonsillitis."

And the mother, who had seen Leonard come through his illness, never sent for you ?—No.

Had you any reason on the 1st August when you left that house to suppose that the child was in a serious condition with diphtheritic symptoms or any serious symptoms ?—None whatever, the child was very much better.

I am speaking of the 1st August.—None whatever.

Some diseases are more infectious than others, I suppose ?—Yes, that is so.

Or contagious ?—Of course, some are contagious and some are infectious.

Was Leonard's illness infectious or contagious ?—It would be contagious. I should not like to say that it was infectious.

It would not follow from its being infectious or contagious that it was anything more than what people call an ordinary sore-throat ?—No, it is the kind of thing that runs right through a house; we have had thousands of them in Gloucester lately. There was a regular epidemic of sore-throats and I have treated a vast number.

Does not that indicate a germ origin of the disease ?—No, I think it indicates a peculiar state of the atmosphere. These cases of tonsillitis are very common in Gloucester. We lie very low here and the atmosphere is very humid. The schools are very crowded, and diphtheria increased very materially after the passing of the Public Education Act when all the schools became crowded with children. The same thing applies in a small scale all the way round.

Mr. VACHELL. Your Lordship rather stopped my learned frind, Mr. Micklethwait, when he was examining the mother on the subject of Leonard's illness.

Mr. JUSTICE LUSH. I was not conscious of having stopped Mr. Micklethwait.

Mr. VACHELL. Yes, my Lord, there was an objection by my learned friend as to one of the symptoms in Leonard's case. Now surely it has become of some importance as to whether that symptom did exist ?

Mr. JUSTICE LUSH. If I did, it has become more important now. I did not at that time, of course, think we should have to go into Leonard's case at all. I think you ought to be entitled to recall the mother.

Mr. VACHELL. I wanted to put a question to Dr. Hadwen upon it, but we will have her evidence first.

Mr. JUSTICE LUSH. Certainly.

ANN MARIA BURNHAM, *recalled.*

Further examined by Mr. MICKLETHWAIT.

I want to ask you a question about Leonard, He was taken ill on the 19th July, I think ?—Yes. that was the date, I think.

Did anything happen after he had been ill two or three days? Do you remember anything happening?—I do not know what you mean.

At night do you remember anything happening?—No.

Do you remember him in bed on the night of the 24th?—Yes.

I do not want to suggest anything in any way. Did anything happen when he was in bed on the night of the 24th?—Would that be on a Thursday night?

Yes, I think it was?—It was on a Thursday night he brought something up out of his throat.

What was that something?—It looked almost like indiarubber to look at. I had been giving him some slices of lemon and sugar to suck.

What colour was it?—It was about the same colour as rubber.

Do you mean a greyish colour?—He brought it out of his throat because I had seen what was in the children's throats.

Had you seen anything like that in his throat before?—Yes, I saw it when the doctor came, in each child's throat, in the two children, both Leonard and Nellie's. It was there the first day the doctor came plain enough for him to see, right across their throats. Their throats were full.

And on the 24th Leonard brought this piece up?—Yes, on the Thursday night.

Further Cross-examined by SIR EDWARD MARSHALL HALL.

Do you remember seeing the child hawk up great lumps of mucus from the throat? Do you know what it is? Have you seen the great lumps of stuff people get up when they have a cough?—Yes. It was not like that.

You say it was something like rubber?—Yes, I did not look at it long; it smelt so badly.

Did you ever tell Dr. Hadwen that the child had coughed up a piece of rubber?—No, he only came once after that.

MR. JUSTICE LUSH. Did you ever tell him?—No, I did not; he saw the children's throats every time he came. He ought to know.

MR. VACHELL. Now I ought to put a question to Dr. Hadwen.

SIR EDWARD MARSHALL HALL. In this book, Bosanquet and Eyre, it says "It may also be found in a virulent condition in the throats of healthy persons."

DR. WALTER ROBERT HADWEN, *recalled.*

Further Cross-examined by MR. VACHELL.

You have heard what Mrs. Burnham has said, that Leonard had something visible across his throat inside; what do you say to that?—All I can say is I never saw it.

If you had heard that he had spat up something of the character that she has described, would that have altered your opinion as to what he was suffering from?—I should like to have seen it first.

Was it the sort of thing you might expect in a diphtheria case?—I do not know why I should. This is not a diphtheria case.

Is it the sort of thing you might expect; is it one of the incidents in diphtheria that the membrane becomes loose?—But the membrane never comes away in a large mass, as is described by the mother. Membrane always comes away from the throat in small pieces.

That is always so, is it?—Always so.

Dr. Washbourn found a piece I think he described—

SIR EDWARD MARSHALL HALL. This witness was recalled for one purpose only.

MR. VACHELL. If my friend would have a little patience. I have had some experience. My friend s so very jumpy. (To the Witness.) Dr. Washbourn ells us of a piece three inches by one; do you call hat a small piece?—No, I consider that a very large piece, and that leads me to conclude it came from below and not from above.

MR. JUSTICE LUSH. Unless the doctor sees it and knows what it is like, I do not see how he can be asked to say whether it would indicate diphtheria: that is the trouble.

MR. VACHELL. If your Lordship pleases, I quite accept that.

SIR EDWARD MARSHALL HALL. Is what is called croupous pneumonia diphtheritic necessarily?—Oh dear no.

Is croup diphtheritic?—No.

Therefore, when the Registrar-General has combined diphtheria and croup, does croup necessarily include diphtheria?—Oh dear no.

So, as regards these figures that my Lord has very properly pointed out to you, if you add the two columns together or deduct the second column, that is the sum of the first plus croup and if you take a subtraction of it and take one year 1895——

MR. VACHELL. Is this re-examination?

SIR EDWARD MARSHALL HALL. It is on the question of the presence of a membrane coming up.

MR. VACHELL. Let me ask your Lordship to look at the table itself; it is called membranous croup.

SIR EDWARD MARSHALL HALL. No, it is diphtheria and the other is diphtheria and croup.

MR. VACHELL. Membranous croup is the only croup notifiable.

SIR EDWARD MARSHALL HALL. Now my friend has added that. I do not see the words membranous croup. What has happened is that the doctor has obviously taken the one column and not the second column. If the second column which talks of diphtheria and croup means croup which is diphtheritic, then it is perfectly proper to take it as comparable as a figure of diphtheria, but if it means diphtheria and croup, that is croup which is not diphtheria, then it is not the proper column to take in comparison.

MR. JUSTICE LUSH. It is quite obvious when you examine those returns they do not justify, it seems to me, Dr. Hadwen's statement that the number of cases had increased instead of diminished.

SIR EDWARD MARSHALL HALL. Unless you take the one column of diphtheria only. If you do that, Dr. Hadwen is accurate, but if you take the next column, diphtheria and croup which Sir William told us contained the preceding column plus the croup cases, then I agree Dr. Hadwen is inaccurate.

MR. JUSTICE LUSH. That is the difficulty.

SIR EDWARD MARSHALL HALL. I will leave it at that. I do not call any other witnesses, and that is the case for the Defence.

CLOSING SPEECH FOR THE CROWN.

MR. VACHELL then addressed the jury. They would be asked, he said, when Mr. Justice Lush came to sum up, to consider whether there was in this case culpable neglect on the part of Dr. Hadwen, and if so, did that neglect either cause or accelerate the death of the child.

The first matter that one was bound to consider in dealing with the question was whether the child ever had diphtheria. As against all the evidence for the prosecution they had simply the evidence of Dr. Hadwen, the most interested person in the case. His whole anxiety naturally was to escape from the charge that was made against him, and although his (counsel's) learned friend (Sir Edward) had rattled about a number of books and read from Dr. Hadwen's pamphlets passages concerning his theories and effusions, not one single medical man had been called before them into the witness-box to support any of those views and theories that the doctor had lectured to them upon so eloquently from the witness-box. That perhaps would be more important when one came to consider the merits of antitoxin than when one was dealing with this first question as to what the child was suffering from. It might also be helpful on the question of pneumonia. But Dr. Hadwen stands alone, and says, in effect, "you must discredit all the witnesses for the prosecution, accept my theories on disease and upon germs of disease, put on one side the whole weight of the professional medical men of this and almost every other country; I don't believe them, I have no regard for them; accept your facts from me."

Going on to review the evidence, Mr. Vachell asked the Jury if they thought the mother of the child had any animosity against Dr. Hadwen and if there was any reason why she should come to Court and make up a story against him. You are the judge of her, he said. There is no doubt that now she feels very strongly and feels very bitterly against Dr. Hadwen. But she told most of this story, I think, at the inquest, which took place a few days after the child's death. All the witnesses had spoken of just those symptoms which attended most cases of diphtheria. There was, too, Dr. Ellis, who saw a piece of membrane in the throat of the child when he was called in on the night preceding death, and further, how could the Jury give the "go by" to Dr. Washbourn's evidence? How are you going to deal with all the evidence? Mr. Vachell asked. Are you going to say there is a sort of conspiracy between all these people to do an injury to Dr. Hadwen, and that these people are deliberately committing perjury in order to achieve their end?

Sir EDWARD MARSHALL HALL here interposed to say that he had never made any suggestion that the witnesses for the prosecution were committing perjury.

Mr. VACHELL. I have never said that you made the suggestion.

He would venture to suggest, Mr. Vachell continued, that it was impossible to put aside the evidence as evidence they could not act upon without coming to the conclusion that much of it had been invented. The witnesses all spoke of actual facts, saying, "We saw this, that and the other." And if that evidence was accepted, the symptoms of diphtheria were present and were observable in the child. Dr. Hadwen did not treat Leonard's case as diphtheria, but it was probable that it was diphtheria, and was the one which brought the disease into the family.

Dr. Hadwen preferred not to give antitoxin. The question of antitoxin was more than a belief with the doctor, it was a religion, and they could see that. From what the doctor had told them it was perfectly obvious that it was not only a matter of eliminating it from his own practice, but he regarded it as pernicious and, he (Mr. Vachell) thought, almost as wicked. Dr. Hadwen had said he would not give antitoxin, and would try to prevent others giving it to his patient, and it was worthy of consideration whether the true explanation of the doctor's conduct throughout was to be found in that and based upon that. Might it not be that the doctor was prepared to call and treat it as tonsillitis rather than notify the case, which would mean going to the isolation hospital? They would have to consider whether that was the cause of death or accelerated the death.

Mr. Vachell went on to refer to the difference between lobar and lobular pneumonia. Dr. Hadwen's theory was that the child got pneumonia in consequence of a chill caught by going downstairs, and was something for which Dr. Hadwen said he could not be held responsible. They had evidence to show that the pneumonia, whether it was lobar or lobular, was a direct consequence of the diphtheria. It was to the advantage of Dr. Hadwen that it was called in this case lobar, which was more likely to be caused by a chill, but both Sir William Willcox and Dr. Washbourn were clearly of opinion that the pneumonia was a sequela to the diphtheria, and secondary to it. There was no evidence which would support Dr. Hadwen's views on the matter. There was the cogent evidence of the post mortem of the track of the fell disease from the spot where probably the membrane was created right down to the lung, which became involved and eventually acutely congested. They had evidence that the child was unable to withstand the added ravages of the pneumonia because she had not been given the proper treatment for diphtheria.

The next thing, proceeded Mr. Vachell, they had to consider was how far Dr. Hadwen could be said to be criminally liable for what he did. Much depended on what he actually saw. The case for the prosecution was that antitoxin ought to have been administered on his first visit. If Dr. Hadwen, in the excess of his zeal for doctrines which are believed in by but few of his fellow practitioners, wilfully shut his eyes to the symptoms and persuaded himself to believe that this was not diphtheria but something he might call tonsillitis, and if he were prompted in that by the knowledge that if he called it diphtheria the child would receive antitoxin treatment, that was neglect on his part of so gross a character and so tinged with feeling, that he neglected to give care and assiduity to his patient and indulged in his own special whims and theories in medical matters, that it surely came within the range of criminal neglect. A doctor's first care must be his patient, not the airing and practice of his own peculiar views, and if there were a recognised method of dealing with a disease, and if the results as shown by statistics were greatly in favour of the use of that particular remedy, was a doctor to say, because he had acted on a general theory differing from that of all other medical men, that he was to allow a child to run a risk which would not exist if the child were given the antitoxin treatment by someone more orthodox than himself? Was it the sort of care that poor people were entitled to expect even if they paid only a small fee for the services of a doctor?

One thing, Mr. Vachell said in conclusion, which had done good to mankind and saved a large number of lives was the particular serum which Dr. Hadwen chose to despise. He had sufficient before him to make him suspicious of diphtheria, and he ought to have taken steps which all prudent doctors did. He should have taken a swab and sent it to Dr. Washbourn, and the antitoxin treatment should have been applied, when in all human probability, the child's life would have been saved. Instead, he went on his somewhat curious views upon the whole subject of antitoxins and the whole question of bacilli and germs—views which no one had come into the box to support. He chose rather to take things into his own hands and treat the case as one of tonsillitis. That was something so gross and so unfair to both the patient and the poor mother that the Jury should feel bound, for the protection of public welfare, to register a verdict that would show that they regarded it as so gross as to make it punishable as a crime. Dr. Hadwen's answer to the various points which had been put before them in evidence was of practically denying everything. He opposed his unsupported opinion against that of every medical man. Were the Jury going to support that sort of treatment for children of the poor? Such children were entitled to as much care and attention, and with as much skill, as the children of those who were better off. He had no doubt that Dr. Hadwen was sincere in his somewhat unusual beliefs, and the probability was that those beliefs made him deliberately close his eyes to the true condition of the child. If he had done his duty and exercised proper care, and had properly examined the throat and looked at the symptoms, taken a swab and administered the antitoxin treatment which he abhorred, the strong probability was that the child would never have died.

(*Adjournment for lunch.*)

Mr. VACHELL. My Lord, Sir William Willcox, who was called away, has left an analysis of those figures that were dealt with. I have shown them to my learned friend, and he does not object to your Lordship having them. (Same handed.)

Sir EDWARD MARSHALL HALL. The whole thing is really dependent upon whether membranous croup is the only thing included in those figures. I am only going to deal with it on the question of bona fides to show that Dr. Hadwen read it as the Registrar-General published it. It was the fresh information which enabled him to say what he did.

CLOSING SPEECH FOR THE DEFENCE.

Sir EDWARD MARSHALL HALL addressed the Jury. He said he realised the importance of this case, and he only hoped the Jury would also realise its importance, because it was not only this particular case they were dealing with—the effect of a verdict in a case of this kind must have very far-reaching consequences. Dr. Hadwen was charged with manslaughter, and the Jury had to find their verdict on the evidence. The law had to come entirely from his Lordship, but on the facts upon which the legal position would have to be founded they were the sole judges, and they would be asked to say whether Dr. Hadwen was guilty or not guilty.

The onus of proving him guilty rested entirely with the prosecution, and if the prosecution failed to satisfy the Jury beyond all reasonable doubt that he was guilty, he was entitled to be acquitted. What constituted an offence of manslaughter in this case? Had Dr. Hadwen been guilty of such wilful and culpable neglect that it accelerated or caused the death of the child Burnham? As to what was wilful or culpable neglect, his Lordship would give them guidance, but he (counsel) submitted that there was absolutely no evidence upon which they could reasonably be satisfied beyond all doubt that Dr. Hadwen had been guilty of any wilful or culpable negligence. The case for the prosecution was dependent almost entirely upon the evidence given by that most eminent medical man, Sir William Willcox, for whom he (counsel) had the greatest and most profound regard. But he was not in a position, however great his position might be, to come down and say there was an absolute rule of practice by all qualified men that on suspicion of diphtheria they must take a swab and must inject antitoxin. He (counsel) submitted with the greatest confidence that it would be a terrible day for this country, for the medical practitioners as much as for the people who were their patients, if any such broad proposition of law was laid down.

The Jury had to ask themselves, Sir Edward went on, whether Dr. Hadwen diagnosed the case as one of diphtheria, and if he did not, was it an honest diagnosis or did he wilfully, by reason of his prejudice against the well-known fashionable diphtheritic treatment, and deliberately shut his eyes to the symptoms which otherwise he ought to have seen. In his submission, although he was not saying it was irrelevant, it was only of collateral relevancy that it was a fact that the child was suffering from diphtheria, because if the Jury were satisfied that the child was suffering from diphtheria in such an aggravated form as to be mainly responsible for its death, then they might say it was incredible that a doctor with Dr. Hadwen's experience should have honestly mistaken those symptoms. That was really the test of the case. Although they had the word of four medical witnesses that the child died from diphtheria, it was not conclusive against Dr. Hadwen, and it was only so far as that evidence affected Dr. Hadwen that it was of importance to the case. Dr. Hadwen had 35 years' experience, and as the Divisional Court had said on a previous day, he was entitled to the benefit of any reputation he had earned among his fellow citizens in the great city where he practised, however much they disagreed with the extremity of his conclusions and ideas, and he was before them as an honest man who had earned and deserved his reputation. Dr. Hadwen said he did not diagnose diphtheria, and that it was not diphtheria so far as he knew; but, unfortunately, he could not say whether that was right or wrong by reason of the unfair way in which he had been treated in the case. Dr. Hadwen took up the position that he did not agree with Dr. Washbourn, because the pneumonia was lobar and was not the class of pneumonia which was consequential on diphtheria.

With regard to the membrane found at the post-mortem examination, Dr. Washbourn had agreed that it could not be properly distinguished unless it was microscopically examined. That was where the prosecution had been in a dilemma, and the Jury could not, as asked by the prosecution, rely upon the visual examination of membrane and rely upon visual examination to settle the question of the kind of diphtheria the child had. There was also the question of the possibility of affection of the heart, which Sir William Willcox had told them should have showed signs of fatty degeneration. Dr. Washbourn said that the heart appeared to be normal and healthy. If the Jury were satisfied that the girl had lobar pneumonia and that the heart was normal, they had two important factors which militated against the diphtheria theory. Upon that point alone there arose an element of doubt, and he asked them to say that the girl had lobar pneumonia consequent on a chill got by going downstairs at night. Dr. Hadwen's statement that the child was better on the Wednesday morning was borne out by the fact that the child was able to go downstairs. If, as the mother said, the child got rapidly worse of the diphtheria after the visit of the doctor on Wednesday, was it credible that she would be able to go downstairs in a condition of increasing diphtheria?

If, continued Sir Edward, they thought the evidence proved that the child did go downstairs in her bare feet to get some water, contracted a chill, and as a result of that chill contracted lobar pneumonia from which she died, Dr. Hadwen was not guilty under any consideration. Had the Jury any doubt about it? According to the mother's evidence, the next morning the child was seized with vomiting, and was much worse on the Saturday morning, when Dr. Hadwen was staggered by her appearance. Yet, according to the mother, Dr. Hadwen, within 14 hours of the child's death, said then there was nothing whatever the matter with the child, and that she would soon be quite well. Was not that so incredible that the Jury would refuse to believe it? If they did not believe it, what was the other evidence of the mother? There were two points which he (counsel) regarded as of vital importance in this case. One was the admitted fact that the child ran the risk of incurring a chill, and secondly it was an admitted fact that the pneumonia was the pneumonia one would expect to find following such a chill. The mother no doubt felt she had a grievance against Dr. Hadwen, for though Dr. Ellis told her he was prepared to give a certificate of death, she insisted upon the holding of an inquest to have all the facts investigated so far as they affected Dr. Hadwen. In her earlier evidence there was no specific mention of the now much-relied-upon nasal discharge, streaked with blood; and, what was more, though she knew the child had run downstairs and had incurred the risk of a chill, never once did she tell the doctor of these incidents; and neither did she tell the Coroner, until cross-examined by Mr. Clements for the defence. Did the Jury think it a fair thing to do—to hold back from the doctor facts which might be very important for consideration in connexion with the question as to what the child died of. There was, suggested Counsel, a suppression of something—an omission to state something by the mother which lent colour to the suggestion that she had to some extent coloured her evidence.

The next point was: Were the Jury going to believe Mrs. Taylor? She was a sister of Mrs. Burnham. They saw her in the witness-box, and he would ask the Jury to bear in mind her demeanour as a witness. When before the Coroner she said the child tried to vomit a quarter of an hour before her death, but did not bring anything up. Before the Magistrates she said the child tried to vomit, and a little came from her throat when she lifted her head, and when cross-examined she said she stated nothing at the inquest as to anything coming from the mouth of the child, because she only paid attention to it since the various doctors' evidence. Now, before the Jury, she had stated that she could see something in her mouth, and saw something slip from her mouth—a small piece of slimy, yellowish skin, streaked with blood. Did the Jury believe one word of that statement?

Was not that the final stage of colouring? If that was the nature of Mrs. Taylor's evidence, could they rely upon the evidence of the other witnesses who were called, and who were members of the family council? They had been in close contact with each other. He (counsel) would not say that they had invented the story, but they had persuaded themselves to believe that what they said really did happen.

The Jury might think, Sir Edward went on, that Dr. Hadwen was obstinate, that he was wrong, that his views on medicine and medical matters were somewhat eccentric, but he hoped they would not believe the suggestion that he was the only medical man in England who was opposed to the administration of antitoxin. In this case it was admitted that Dr. Hadwen had given the boy the best attention, and this was the weakness of the case for the prosecution. Here they had to explain away something. Dr. Hadwen said the boy never had diphtheria, but ulcerated tonsillitis. He treated him and cured him, and treated Nellie in the same way and would, he claimed, have cured her if she had not been exposed to the chill. The importance of the point was that a swab was taken from the boy's throat, and was returned as negative. Was Dr. Hadwen to be charged with manslaughter and convicted because he omitted to give the child on what was the third day of illness antitoxin, treatment of which he strongly disapproved? or charged and convicted of manslaughter because he did not take a swab and call in another doctor to administer the antitoxin? or because he was said to have failed wilfully and neglectfully to diagnose diphtheria, but treated the child for another disease? Sir Edward commented upon the fact that Dr. Hadwen had opposed having the trial elsewhere. He was entitled, he claimed, to be tried in Gloucester before a jury of his fellow-citizens, hence these proceedings at Gloucester.

Where was the negligence? Sir Edward asked, and asked with confidence. Where was the culpable negligence? Mistaken diagnosis possibly—probably if they liked. If they thought Dr. Hadwen was wrong and the child was suffering from diphtheria, that was a chance which everyone took when a doctor was called in. No doctor was infallible, and no doctor was liable for an honest mistake. No one could say that was manslaughter. He agreed that if the Jury thought Dr. Hadwen prejudiced his mind to such an extent as to shut his eyes deliberately to symptoms he ought to have seen were those of diphtheria because he did not want to notify it and expose the patient to the possibility of the use of serum inoculation, then it was another matter. If, however, they believed that the doctor was fortified in his diagnosis by what had happened in his treatment of a case of follicular tonsillitis with identical symptoms, there was an end of the case. They could not, if they believed the doctor, say it was a wilful and negligent diagnosis. If they thought that they could not return a verdict of guilty.

Sir Edward regretted that he must refer to Dr. Ellis's behaviour in the case. He was sorry Dr. Ellis had done what he did, and he was sorry to have to say what he was going to say. It was an unfortunate thing that the doctor called in in this case was the doctor who had been the most bitter opponent of Dr. Hadwen in the public press in the preceding year, and who was the man who had gone so far as to write to the editors of newspapers offering to give information detrimental to another doctor's professional position. He (Sir Edward) had a very high opinion of the medical profession, which was bound by a stringent etiquette, and he thought Dr. Ellis, when he thought the matter over in the quiet of his surgery, would regret, having regard to the bitter hostility between Dr. Hadwen and himself, that when he was asked to attend a case where Dr. Hadwen's conduct was to be called in question, he did not suggest some other doctor should be asked to attend. Dr. Ellis knew of the death of the child on the Sunday, and although he was on the telephone he did not inform Dr. Hadwen. While all that was bad, what was to follow was worse. It was true that under the present system the Coroner was absolute master of his own court. He could summon through his officer whatever jurors he liked and no one could say aye or no. He could order a post mortem, and whether the person who was most concerned with the result of the post mortem was consulted or not depended upon the Coroner, as did the fact whether he could be there represented. The City Coroner was away on his holiday, and the Deputy Coroner—a medical man—attended the post-mortem examination. Dr. Hadwen, who was a skilled, duly qualified man, although he was concerned in the result of the post mortem, was not present, although it was known that there might be a charge against him. In that case nothing had come out clearer than this. Had Dr. Hadwen been allowed to be present many of the questions left in doubt would have been definitely and finally cleared up. It was little less than a public scandal that the Coroner should not have given Dr. Hadwen an opportunity to be present at the post mortem, or his representative.

In conclusion, Sir Edward said the Jury must be satisfied that the child died of diphtheria, which was the result of negligent treatment by Dr. Hadwen before they could bring in a verdict of guilty. If they were not satisfied he was entitled to be acquitted. Confident that he could get a fair trial from his fellow-citizens of Gloucester, he (Sir Edward) left Dr. Hadwen in their hands. Whatever they might have heard outside, whatever prejudice might have been imported into the case by the cross-examination of Dr. Hadwen, they would judge the case on the evidence given within those four walls according to their oath, "A true verdict give, upon the evidence." If they did that he, like Dr. Hadwen, had absolute confidence that they would do justice to the doctor and the prosecution. They had to hold the scales of justice between the two, remembering that the prosecution must put so much into the scales that it must outweigh beyond all possibility of error the scale in which the defendant's innocence rested.

THE JUDGE'S SUMMING-UP.

Mr. Justice Lush. Members of the Jury, we have now reached the last stage of this very serious and somewhat unusual case. You have listened to two very powerful speeches, and it is now my duty to sum up the evidence to you, after which it will be your duty to say what your verdict is.

There is one word I wish to say now at the outset, although I hope and think it is scarcely necessary for me to say it. This case, as we all know, has excited a very unusual degree of public interest, I might say excitement, and it may be before you went into that jury-box you heard the case discussed. You heard opinions expressed with regard to Dr. Hadwen and his conduct with reference to the child. I am quite sure that you in considering your verdict will not allow anything you have heard outside this Court to weigh in the least with you, or to have the slightest effect upon your judgment. In a Court of Justice we have to consider one thing only, and that is what is the true conclusion to come to having regard to the evidence that has been placed before us, and you will, I know, apply that method, and that method only when you come to ask yourselves, ought we to find a verdict of guilty or a verdict of not guilty. You have heard the evidence, and by that evidence you will come to your conclusion.

The case is undoubtedly, as I have said, a very serious one. It has consequences that extend beyond those who are personally concerned in this case. A charge of manslaughter is brought against a medical man who has for some 30 years been following his profession and practising in this city of Gloucester, and, of course, to him it is a matter of the utmost importance. It is a matter of great importance to the public, to the community, and, I may say, to the medical profession, because while on the one hand children and others are entitled to be, and must be, protected against criminal neglect, criminal misconduct on the part of a medical man, it would be deplorable and disastrous if a medical man following his profession according to the best of his judgment, and acting honestly in the treatment of a patient, were to think that he had hanging over his head a weapon like this, and a fear like this if anything should go wrong with his patients. It is a case which of course requires strong and clear proof on the part of the Crown, and it is only if you are convinced by the evidence that has been called by the Prosecution that Dr. Hadwen was guilty of criminal wicked neglect, and if you are also convinced that it was that criminal and wicked neglect that caused the death of that little girl, that you can find a verdict against him, and if the Crown, upon whom of course the burden rests, have failed to bring home this criminal misconduct to him, he is entitled to a verdict of acquittal.

Now it is of the utmost importance that you should realise and always bear in mind this fact. You are not sitting as a jury merely to criticise Dr. Hadwen's views. You are not here to say merely whether he has or has not adopted views which, in your opinion, a wise medical man ought not to adopt. The charge against him is that he caused the death of this little girl. The indictment in its form says that he did feloniously kill the child, and it is a vital part of the case that the Crown has to establish not only that he neglected her—I will say a word about that in a moment—but that his neglect did actually cause her death. I want to say a word first about the last of those propositions—namely, that his neglect caused her death. Many cases have been tried in these Courts in which a medical man, sometimes an unqualified man, has undertaken the cure of a patient, and has in the course of the endeavour to cure the patient chosen to administer a dangerous drug or perform some operation in the hope that it would do good to the patient. If the drug was administered, or the operation performed, in such a disgraceful, careless fashion, or performed with such a disgraceful ignorance as to what the effect of the drug would be, or as to the way in which the operation ought to be performed, and the patient died then there is no difficulty in saying in such a case that the doctor or the operator caused the death of the patient because what he did naturally would have destroyed life. But the peculiarity of this case is this. Nobody suggests that Dr. Hadwen did anything, administered a drug, or performed an operation, or did anything else which caused the death of Nellie Burnham. What is said is that he was so neglectful in his diagnosis and in his treatment that the child, whose life would have been saved if proper care had been used, died through that neglect, and the Crown therefore have to prove this, not only that there was the neglect but that she would have had her life saved or prolonged, because to cause death is the same as to accelerate death for this purpose. It must be proved that her life would have been prolonged before you can say that proper care had not been used. One is met, of course with this difficulty. Who can tell what would have happened to the patient, assuming there was neglect on Dr. Hadwen's part, if proper care had been used? Of course one cannot say for certain what would have happened. The disease might have run its course favourable to her. It might, on the other hand, even with care, have ended as this did, but the way in which you must deal with this question is this. If a doctor is culpably negligent in his treatment of a patient, and if the patient dies, it is not enough for the Crown in supporting an indictment of manslaughter to prove that if the doctor had been careful the patient would have had a chance of getting favourably and successfully through her illness. They must prove more than that. They must prove that in all human probability if care had been used the child would have recovered, and if the Crown have established to your reasonable satisfaction, first, that the doctor did neglect the child, and secondly, that in all human probability the child would have recovered if he had not neglected her, then, and then only, can the Crown ask for a verdict of guilty. I will tell you why I have dwelt so strongly upon that, and why I must urge you to bear it most carefully in mind.

There are two quite distinct questions that you have to deal with in this case. The first is whether there was that culpable neglect on Dr. Hadwen's part, and the second is that which I have just referred to, if there was the death was the death caused by it, and there are certain matters which you have got most carefully to consider even if you think that the neglect has been proved by the prosecution, and I will tell you what they are. I have mentioned before that that date of August 1st is an important one, and it is also obvious that the question of the pneumonia, how it came about, and how far it played a part in the death of this unfortunate child, are the two questions which I am going to say a word about, and which have an important bearing upon the death of the little girl. The doctor was called to see the child on August 1st. The doctor had been attending Leonard. Leonard, he told us, suffered from a worse throat than he found the little girl suffering from when he went there on the 1st August. Knowing that Leonard's throat was very bad he had attended Leonard consecutively for some three or four days. We know when the doctor called in to see Nellie he only attended her on the 1st August, and did not come again till the 4th. One must try and get at the answer to this question, which to my mind is an all-important one in this case. Whatever may have been the child's condition on the later days in August, up to the 9th when she died, what was her condition upon August 1st? Did she then show such signs of diphtheria or such symptoms as would make an ordinary doctor suspect diphtheria and take precautions against it, or did she only show signs of what one may call an ordinary sore throat such as Leonard had had and from which Leonard had just recovered. If the latter is the true view, if you come to the conclusion that on August 1st there was nothing to suggest to Dr. Hadwen that the child was suffering from a serious throat, a throat which would require serious care and steps to be taken, it seems to me then that there is this difficulty in the way of the Prosecution, and I want you to bear this in mind. The doctor went again on August 4th. August 4th, you know, was six days after the commencement of the child's illness, because the child was taken ill on July 30th. August 4th is six days after that. We know from Sir William Willcox, indeed we know from all the doctors, that unless this antitoxin is given within six days it is practically ineffective. It is practically useless to give it, and if the truth is that Dr. Hadwen had no reason until August 4th to suspect that there was anything seriously wrong with the child's throat, it seems to follow—it is for you, not for me to judge—that even if he did after August 4th neglect the child that did not really affect the child's recovery. It certainly would not make the withholding of the antitoxin a matter of any serious importance, because unless antitoxin had been given within six days the doctors have told us it is practically useless to give it at all, and therefore I do myself attach, and I ask you to attach, the greatest importance to this question: What was the condition of the patient when Dr. Hadwen was first called in to see her on that day in August. If she showed signs of diphtheria, if he then and there ought to have said to himself: "Well, this is a serious case, I must give it close attention," then you will have to ask yourselves whether he did give it the attention that the case deserved, having regard to the symptoms. Then it will become important for you to consider whether he ought or ought not to have taken a swab, sent it to the bacteriologist, and administered antitoxin, which you are told is the course that ordinary careful doctors follow. But if, on the other hand, on August 1st this little girl was only showing the same symptoms that Leonard had shown, if there was nothing serious in the throat, nothing to call the doctor's attention to the fact that there might be diphtheria, there might be some serious malady in the throat which no one would think of criticising him for not taking a swab, and for not administering antitoxin. Therefore you have to bear in mind, to my mind, the importance of that date, and ask yourselves whether the Crown has proved to your reasonable satisfaction that on that 1st August the child did show signs of a serious malady which the doctor with gross neglect refused to consider. So much for that part of the case.

The other factor which bears upon the question whether the death was caused by this alleged neglect is this question you have heard so much about, of the pneumonia. If the pneumonia was really the sequela, the secondary consequence of the diphtheria, then if the doctor is responsible for the diphtheritic condition continuing, of course he would be equally responsible for the pneumonic condition, because that would follow as a consequence of the diphtheria. But if, on the other hand, the pneumonia was brought about by an entirely independent act, the unfortunate act on the part of the child of getting out of bed, going downstairs, walking with bare feet upon the tiled kitchen, and then going back to her bed, if in fact it was that which caused the chill, and the chill caused the pneumonia, and the pneumonia caused the death, then one cannot say, it seems to me, that the neglect on the part of the doctor in the earlier days in August had anything to do with causing the death of the child. Therefore you have to consider this question with reference to pneumonia from that point of view. Did the child die of pneumonia? If she did, was the pneumonia the consequence of the diphtheria which the doctor, as the Prosecution say, ought to have discovered and treated in the earlier days in August, or was it the consequence of something the child unfortunately did for which nobody can suggest that Dr. Hadwen is responsible. Those are the two things, to my mind the important factors for you to take into account when you come to consider the second of the two questions you have to deal with, namely, did the neglect in fact cause the death? If it did not, all I can say is that there is an end of this case, because unless the Prosecution can prove that the neglect by the doctor did cause her death, they cannot ask you to find a verdict of guilty against Dr. Hadwen.

Now I will come back to say a few words about this question of neglect. The law does not say that if a person who is attending a patient, a doctor attending a patient, is unfortunate enough to have an error of judgment, or even unfortunate to commit an error of judgment because he does not take all proper care and the patient dies, that he is guilty of manslaughter. The law does not cast upon anybody who is merely careless, and whose carelessness is the cause of the death of another, the responsibility of defending himself in the dock against an indictment for manslaughter. There are many cases in which a person is guilty of negligence, and that negligence causes the death of another person, where that man who causes the death of the other through his negligence may have to pay damages for his negligence, but certainly he could not be indicted for manslaughter. Unless the negligence of which the person is guilty who does cause the death of another is of so gross a character as to make one say of it, "Well, that is wicked negligence, it is not mere carelessness, it was a wickedly careless thing to do," a man who causes another's death cannot be convicted of manslaughter. There must be something evil in the negligence, something culpable, something criminal in it, before an indictment for manslaughter can be sustained. Therefore the question you have to ask yourselves upon this question of negligence is not whether Dr. Hadwen failed to exercise that care which a doctor or anybody else ought to exercise, but whether he was guilty of what I have called, and call again, culpable and wicked negligence. If he was, then the Crown have proved the first of the two things they have to prove. If he was not, then the Crown has failed even to prove the first step, and of course that will be a verdict of not guilty.

Now let us consider how the evidence stands with regard to this question of neglect. There is no doubt about this, that a doctor who undertakes the charge of a patient, whether he does it for a reward or gratuitously—it does not in the least matter—is bound to give to that patient all the care which any ordinary doctor in ordinary circumstances would give to a patient. He is bound to do that. If he fails to do it, then, as I say, one has to ask oneself was that merely an error of judgment, carelessness which he ought not to have been guilty of, or is it something worse where the circumstances are such in which one would characterise that negligence as culpable and wicked negligence. What is said on behalf of the Prosecution with regard to Dr. Hadwen's conduct towards the child is this: "You have some five or six witnesses apart from the medical witnesses, who speak to the condition of the child, and the way in which Dr. Hadwen behaved when he was called in. First of all there is the mother, and I want now to remind you that when you come to deal with August 1st, which as I have told you already is, as it seems to me, such a critical date, you have only got on the one hand the evidence of the mother, and on the other hand the evidence of the doctor. There are no witnesses to corroborate the mother with regard to the condition of the child on August 1st, because the neighbours and the relatives who saw the child did not see the child until August 4th and later. Therefore with regard to August 1st, this critical date, you have nobody but those two witnesses, the mother on the one side and the doctor on the other. The mother says that the condition of the child was obviously very serious. The mother speaks of the thick utterance when the child tried to speak; she says there was this discharge, blood, tinged, coming from the nose; she speaks of the offensive smell, and she says that when the doctor came in and saw all those serious symptoms he did nothing but put his two fingers, I thought she said, into the child's mouth, looked at the throat, and after stopping there two or three minutes prescribed some medicine and ordered a gargle of vinegar and water. She said the doctor never took the child's pulse, and never took the child's temperature. If that is true, of course that is a serious matter for your consideration, because you may well think if that is true, and if you come to the conclusion—I will say a word about this in a moment—that the child was really suffering from diphtheria, that that was something worse than merely carelessness not even to take the child's pulse or temperature; to do nothing except order a gargle of vinegar and water when, according to the evidence of the doctor, if those symptoms did show themselves there was reason at least to suspect diphtheria. You may think that that indicated something worse than mere error of judgment, or mere carelessness. But Dr. Hadwen says that the mother's evidence is entirely untrustworthy. He says so far from this being true, that he never took her pulse and never took her temperature, he did and he gives you the results. He says there was no discharge; there was no smell, and he says this little girl showed no symptoms other than those which he had observed in the brother Leonard whom a few days before he had succeeded in curing. That is how the evidence stands upon this date of August 1st. It has been pointed out to you by Sir Edward Marshall Hall that the mother did not in all respects take quite the care, I mean behave quite in the way in which one would have expected her to behave, but one can make all allowances for her, and I am not saying anything against the mother's kindness to the child or desire to be fair to the doctor, but it is to be observed that in that very important matter of the visit of the child to the kitchen on the 7th the mother did not think it right, as one would have expected she would, to call the doctor's attention to it. You may come to the conclusion, it is entirely for you, that the mother in speaking of those symptoms on August 1st is giving an account of the matter which is exaggerated, and upon which you could not safely rely. You have the sworn evidence of Dr. Hadwen against it, and you have no corroboration of her story in the nature of things because nobody else saw the child. As I say, if you come to the conclusion that on August 1st the child was not exhibiting symptoms from which any ordinary doctor would infer a condition of diphtheria or any serious condition at all, it seems to me that you cannot say that on that date the doctor was guilty of culpable and wicked neglect, and if he was not I have pointed out already inasmuch as he did not come again till August 4th I cannot for myself see any ground whatever for saying that he was guilty of criminal negligence in not taking a swab or administering antitoxin. August 4th would be too late to do it with any expectation of getting any benefit from it, and unless it was his duty to do it on August 1st I cannot myself see that his omission to do it on the 1st August can be said to have caused the death of the child.

Now we come to the later dates, because you must take all the dates into account in order to see how the doctor behaved on those dates, and see whether the doctor did then seriously neglect his duty towards this little girl. On the 4th August the mother says the child was in the same condition. On the 6th she says she pointed out the discharge to the doctor, and he told her to paint the child's throat with glycerine, and she says he did not come again; she never sent for him although she knew on August 7th the child had been downstairs and that the vomiting began on the 8th. She never sent for him until the morning of August 9th. The mother says then that the child was very bad, and that the doctor when he came in found her in the condition that the mother described. Then the mother makes this very remarkable statement. She said that although the doctor saw the condition the child was in on that morning—and we know that within 14 hours the child had passed away—the doctor was so careless, so recklessly neglectful of the condition of the child, that he said: "The throat is clearing nicely, there is scarcely anything the matter, she will soon be all right, give her plenty of cold milk," and, says the mother, the doctor said that, although other people there, the other witness whom Sir Edward has commented on, I think Mrs. Taylor, has said the child's condition was such that anybody could see she was in a critical and dangerous state. Is that true? If you think Dr. Hadwen on that morning used language like that of a dying child, because that is almost what she was, you may come to a conclusion adverse to Dr. Hadwen upon this question, Did he act negligently and with reckless neglect towards the child? But Dr. Hadwen says that the mother has made a mistake of the most critical importance with reference to that conversation, and again, curiously enough, comes this difference of date. I ought to tell you that Mrs. Taylor does corroborate the mother, and she says she heard the doctor say, "She will soon be all right." Sir Edward Marshall Hall has called attention to the evidence of Mrs. Taylor and made comments on it, and I need not read it, but Dr. Hadwen says: It is an entire mistake to say he said or thought anything of the kind. He said it was on the 6th August that the child was better, not the 9th, and he said when he got there on the 6th the child was sitting up in bed smiling, and the doctor did think she was getting on nicely. If the mother and Mrs. Taylor heard the doctor say something like what they say they did but if they are wrong in putting that down as being said on the 9th, and in truth it was said on the 6th, it seems to me away goes again this case of neglect, wicked, culpable neglect on the part of the doctor. If you believe Dr. Hadwen, he was justified in saying on the 6th the child was getting on nicely, but Dr. Hadwen says: "On the 9th I was thunderstruck when I saw the change that had come over the child." So far from saying: "She has got on nicely, she will soon be well," he said he was thunderstruck with her, "I could not make out what had happened, the child was so bad." Then he felt the pulse—that the mother admits. She admits he felt the pulse of the child on the 9th. He took the child's temperature, and he said that he saw that the child was in a serious condition. That is how the evidence stands with regard to the matter, and you again have to ask yourselves who is right with regard to that date. The importance of that date is not that it was then time to administer the antitoxin, that time had gone by; it was much more than six days since the illness began when you get to August 9th, but the importance of it is this, how he behaved on that date throws the strongest light, it seems to me, upon his conduct throughout in treating this little girl. If he behaved in the way the mother says on the 9th August one can only say how could he have used language like that, or expressed an opinion like that, when the facts were staring him in the face, and the child died almost within twelve hours. But if what he says is the truth there is nothing in his conduct on the 9th that I can see that would justify your saying that he showed reckless and culpable neglect towards the child. So much for that; I need not trouble you about the other witnesses. Mrs. Peachey corroborated the mother with regard to the state of the child on the 4th. That you need not trouble about; at least I think you may agree with me that you need not be so concerned about it. It was after the expiration of the six days, and she said it was after the expiration of the six days. Mrs. Hotchkins, the aunt, speaks of the child's feverish condition on the 5th, and also on the 8th, and also speaks of the child trying to vomit on the 9th. Mr. Fudge, who I think sent the telephone message telling Dr. Hadwen in the evening not to come again, said he saw the child was very ill on the 7th. That, of course, was a date on which the doctor was not there, and the mother never sent for him on the 7th. He speaks of the child being very ill on the 9th at 9 o'clock in the evening. Then there was Mrs. Taylor, whose evidence I have dealt with already. Therefore you have now the evidence of the witnesses called for the prosecution with regard to all these dates. You have on the other side the evidence of Dr. Hadwen, who deals with these dates, and deals with the child's condition. I do not think it can be necessary for me to read that evidence over to you. You have heard it so recently, you have followed it with such care, but you know that Dr. Hadwen says—I repeat this in order that there may be no possibility of my overlooking anything to be said for him—"I consider that that little girl was not only no worse than Leonard but really less ill than Leonard. I had shown my desire to do my best for the patient so far as Leonard was concerned by going every day when it was necessary," and he says, "I should have done the same with Nellie and gone every day to her if I thought it was necessary," but he said, "I saw nothing in her condition on any of the three days on which I visited her in August to make me believe or even suspect with any real suspicion that she was suffering from any other malady than that which Leonard was suffering from, and that was not diphtheria but an ulcerated sore throat of which Leonard was cured." That is his answer to the case made by the Crown.

I do not think I need go into detail throughout, but you have to judge, and you have to ask whether the Crown upon whom, as I have said, the burden rests, have established to your reasonable satisfaction, that is to say, all reasonable doubt, that the child's symptoms were so grave on the 1st August that you would say that the doctor not only did not use proper care in his treatment of her but that he was guilty of wicked, culpable neglect in the way in which he did treat her.

Now we come to the medical evidence, and the medical evidence is important with regard to this question of neglect in this matter particularly. In one sense it does not matter, of course, whether the child died of diphtheria or whether the child never had diphtheria, but in another sense it is a matter of importance which you cannot ignore, and with which you must deal. If the child never had diphtheria then away goes the case for the prosecution, because the case for the prosecution is that she had diphtheria and that the doctor was guilty of wicked and culpable neglect in not discovering it and not treating it. Therefore one cannot ignore this question and say it is immaterial whether the child did suffer from diphtheria or not; and it is material in another way. The child undoubtedly had pneumonia. The doctors who have been called for the prosecution say pneumonia was the secondary consequence of diphtheria. If the child never had diphtheria the pneumonia cannot have been its secondary consequence, and if the child never had diphtheria the pneumonia must have been caused as far as one can see by the chill the child contracted when she went downstairs on the evening of August 7th. One cannot shut one's eyes, it seems to me, to the importance of the question, Had the child diphtheria? Do not misunderstand me. It does not follow if she had that Dr. Hadwen was criminally responsible. I have dealt with the question of his neglect even on the hypothesis that the child had diphtheria, but if she had not, as I say, the case against him disappears. Was she suffering from diphtheria? Now we come to this very singular aspect of the case. We have heard of Dr. Hadwen's views and mental attitude with regard to the generally accepted theory that diphtheria is a bacillus disease, as to the discovery of the bacillus, and the discovery of its treatment by means of antitoxin. We have heard his views with regard to the correctness of that theory. As I said before, you are not sitting here as a tribunal to criticise these views, to say whether you agree with them or whether you do not. Some people who have heard them may take a very strong view about them, and I think it is legitimate to say it would be very unfortunate if any one doctor were to shut his eyes to improvements in medical treatment which are accepted by the profession as a whole, and to say unless he has good ground for saying so, "I prefer to follow the old-fashioned treatment; I do not believe in these discoveries with reference to the scientific treatment of patients." After all the medical science is a great science. The medical profession is a very great profession, and unless a doctor is going to avail himself of the discoveries that are made from time to time by those who follow the medical profession, one is not likely to see that development of medical science and improvements in medical treatment which one hopes to see. It does not follow from that, of course, that a man who will stick to his own views is guilty of culpable and wicked neglect. A doctor is allowed by our law to practise his profession, if he is properly qualified, in the way in which he honestly thinks is the best, and if a doctor does hold peculiar views, and honestly holds them, and works them out and follows them because in his judgment they are the best methods to apply, or his views lead to the best methods to apply, one cannot say to my mind that he is guilty of any misconduct or any culpable and wicked neglect even though one may think he is terribly sadly mistaken. But I think one can conceive a state of things in which a man whether he is a doctor or anybody else —I do not say this of Dr. Hadwen, of course, it is not for me to pass a judgment upon him; I am not doing or intending to do anything of the kind, but I say it as a proposition which I think is sound—can get his mind into such a state of prejudice in which he can let his judgment be so blinded that really his position is this, that he would rather sacrifice his patient than his prejudices. I do not say that is true of Dr. Hadwen at all. I only say it is a possible state of things, and if a man, whether he be a doctor or anybody else, allows his mind to be so prejudiced, and his judgment to be so blinded, that he is unwilling to avail himself of discoveries and learn things that are being taught by the profession of which he is a member, I can understand a jury saying of such a man that he is guilty of wilful neglect, just as one knows a parent may be guilty of wilful neglect of a child if he refuses to call in a doctor however bad he may be. If he says: "I do not believe in doctors; I do not believe they do any good; I prefer to have faith in his recovery," there comes a stage at which a man must be judged by what he does. If a man is acting honestly, not allowing his mind to be blinded, but is bona fide following out that which he believes to be best, in my opinion he cannot be convicted as being a man guilty of culpable and wicked neglect. It is only when he gets into that state of prejudice I have mentioned that a jury would be warranted in saying, "You have wilfully neglected your patient."

Now we come to this question, Was the child suffering from diphtheria? You have a very powerful body of evidence on the part of the prosecution upon that question. A swab taken, a positive result, and the presence of the bacillus found, and the fact that the bacillus theory is adopted and acted upon by almost every doctor in the land; the evidence you have had with regard to the membrane that came away, and the evidence of the positive diphtheritic result found with regard to the two other children; a strong body of evidence on the part of the prosecution upon this question. You have heard the evidence, of course, of Dr. Hadwen on the point, who, as I say, does hold strong views about the uselessness of this bacillus theory, and you have to ask yourselves whether the child was or was not suffering from this malady. If you come to the conclusion, as I said before, that she was not, of course, the criticism against Dr. Hadwen then all falls to the ground. If you come to the conclusion that she was, it does not in the least dispose of the question, but it is then a factor which, of course, must be put into the scale, and to which proper weight must be given, but even then you are thrown back upon this question of neglect which I have dealt with already, and also you are thrown back upon the question to which I have referred already, namely, did the neglect, if it existed, cause the child's death?

I have said what I have to say about what happened on the 1st August. Let me say a word or two, and this is the last subject I think I need deal with with regard to the question of pneumonia. If, as I have said, the child died from pneumonia, and the pneumonia was caused by a chill brought on by what the child did, it seems to be impossible for you to say that the neglect on the part of Dr. Hadwen to diagnose diphtheria in any way caused the death of the child, and if you think that is the true view then apart from all the other questions you will acquit him upon this charge of manslaughter. What has been proved with regard to pneumonia being the cause of death, and with regard to the pneumonia being caused by the chill and not by the diphtheria? I do not propose to go through the evidence again; you have heard it very carefully sifted. You have heard the powerful comments made upon it by Counsel on both sides. We have got the fact that the mother did not tell Dr. Hadwen of it and give him an opportunity of treating it. He never knew till after the child's death that this had happened, that the child had gone down with bare feet in order to get the water when her mother's back was turned. But what was it caused by, and there curiously enough you have a very strong difference of opinion between Sir William Willcox, that very distinguished bacteriologist and physician, and Dr. Washbourn. Dr. Washbourn's views were, as I follow them, although I think it may be right to say it is not unnatural that in deference to Sir William Willcox's opinion he does not hold them quite as strongly as he did, that at all events in the early stages of this inquiry the lung was lobar not lobular; that that was the natural indication not of secondary pneumonia brought on by diphtheria, but of an independent pneumonia caused by chill. That was his opinion, and he considered that was lobar and not lobular. He agrees in one or two other matters with the views put to him by Sir Edward Marshall Hall as being one side instead of both. The period of three days that elapsed all points, as I follow Dr. Washbourn, to the conclusion that this pneumonia was really the result of the chill the child caught. Sir William Willcox takes another view. He holds the other view. He thinks strongly it was a secondary consequence of the diphtheria. He will not have the view that it was lobar; he thinks it was lobular, and he feels, apparently strongly, that it was a sequela of the diphtheria, and not the result of the chill. But, and you will bear this " but " in mind, it is for the Crown to prove their case beyond reasonable doubt, and if you think, looking at the views entertained by these two distinguished gentlemen, that the Crown have left it in reasonable doubt as to whether the child's death was caused by pneumonia brought on by chill, then I should warn you to be very careful before you convict this Defendant of manslaughter, which you can only do if the child's death was, in fact, caused by the diphtheria, because the neglect alleged against him is not, of course, in allowing the pneumonia to supervene ; the neglect alleged against him is neglect in not discovering that there was diphtheria, and taking the proper steps to get rid of it. Therefore, if the Crown have left this question as to the cause of the child's death in doubt, then can you say that the Crown have proved beyond doubt that Dr. Hadwen is responsible for the death ? I hope you follow what I mean ? The importance of this pneumonia question in this case, to my mind, is very, very great, because, as I say, even though you may, I do not say you will, even though you were to blame Dr. Hadwen for his views, you cannot bring in a verdict of guilty of manslaughter against him, however strongly you may criticise his views, unless, as I have said, you are convinced that that child's death was caused through his neglect.

That is how the case stands. I cannot help saying I agree with Sir Edward Marshall Hall that in a case like this, when there was this strong step contemplated, a step not often taken, I do not in the least say it was not right to take it, but a step not often taken—of putting a practising doctor in the dock upon a charge of manslaughter, that it was unfortunate he was not allowed an opportunity of being present when the post-mortem examination was held, in order that he might see for himself what steps he ought to have taken in order to investigate the cause of the child's death. Unfortunately, he was not told. The microscopic examination of the membrane might, for aught one knows, have assisted him. It was never taken, and he was not there to have an opportunity of taking it. It is an unfortunate incident, and, as I say, I do not ask you to attach too much importance to it, but I did not think it right to pass it over without expressing my agreement with what Sir Edward Marshall Hall said about it.

I do not propose to trouble you with any other observations, or read over any of the evidence unless you wish it. You have heard it all, and followed it so carefully, that I am quite sure it is not necessary for me to remind you of it. If there is anything you want to ask me, and you will do so, I shall be glad to give you any assistance, but I think you are familiar with the evidence, and I hope I have not failed to make clear to you what your duty is when you come to consider your verdict.

May I repeat the salient points, and then I have done ? The burden of proof is upon the Crown. The Crown must establish that Dr. Hadwen was guilty of culpable, wicked, neglect in his treatment of the patient. They must prove that if he had not been guilty of that neglect he would have discovered, in the ordinary course, that the child was suffering from diphtheria. They must prove that the condition of the child at the time was such—I mean that the stage was so early—that by the use of antitoxin the child's life would have been, at all events, prolonged, and they must prove that he was guilty of culpable neglect, or would have been if he had discovered the cause of the malady, in not administering the antitoxin ; that is to say, they must show, in other words, that the death of that child must be laid at his door, because it was he who had undertaken the charge of the child ; that he had the means at his disposal of saving that child's life, and that he wilfully, I mean by that not intentionally, of course, but that he wickedly, and with gross neglect, refused to avail himself of the means at his disposal, and refused to make himself acquainted with what the child was suffering from, and with the remedy he had at hand. If the Crown has proved all those things then, without regard to the consequences, you will say so, and find him guilty. But if the Crown have failed to prove either of them, if the Crown has failed to prove the neglect, or even if they have proved it, and they have failed to prove that that neglect caused the death, then Dr. Hadwen is entitled to a verdict of acquittal. I will ask you now to consider the evidence, and tell me whether you find Dr. Hadwen guilty, or not guilty.

VERDICT.

The Jury retired at 4.40, and returned into Court at 5 o'clock.

The CLERK OF ASSIZE. Members of the Jury, are you all agreed upon your verdict ?

The FOREMAN OF THE JURY. Yes.

The CLERK OF ASSIZE. How say you, do you find the Prisoner Guilty, or Not Guilty ?

The FOREMAN OF THE JURY. Not Guilty.

(Applause in Court.)

MR. JUSTICE LUSH. I tell you this, you who have made that demonstration in this Court, that conduct like that makes one feel inclined to take very great care, in a case of this kind, how far people are to be allowed into a Court of Justice without taking some steps to see that they behave properly. You have no right to make a demonstration of that sort in Court. (To the Prisoner.) You may be discharged.

By FREDERICK W. PRICE, M.D., F.R.S.Edin.,
Senior Physician to the Royal Northern Hospital; Physician to the National Hospital for Diseases of the Heart, London.
DISEASES OF THE HEART.
THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.
With a Chapter on the Electro-Cardiograph.
Demy 8vo. 484 pp. With 245 Text-figures. 21s. net.

Lancet.—"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observation."

Dublin Med. Jour.—"It is probably destined to take the place in the library of the present day physician that was occupied some 20 or more years ago by Sir William Broadbent's well-known work."

Midland Medical Review.—"It is impossible to enumerate the many excellences of this book."

Oxford University Press,
Humphrey Milford, Amen House, London, E.C. 4.

Just Issued. DRAPER'S HUMAN CONSTITUTION. Just Issued.

Dr. Draper's method of evaluating differences in human constitution is rational. It is not a new method of diagnosis, but rather the development of its *application*. Pediatrists use mensuration to determine deviation from the normal. Psychiatrists have directed attention to certain physical characteristics. Cretinism, Mongolian idiocy, &c., have certain distinctive anatomic characteristics. Why should not other diseases have definite physical stigmata? Dr. Draper has found that they have. This book is observation scientifically controlled, and interpreted in clinical terms. It establishes landmarks for measurements; tells how to take measurements, tells how to interpret them clinically.

Octavo volume of 345 pages, illustrated. By George Draper, M.D., Associate in Medicine at Columbia University, New York City. With Foreword by Sir Arthur Keith.
Cloth, **37s. 6d.** net.

BOOKS SENT, CARRIAGE PAID, ON RECEIPT OF PRICE.

W. B. SAUNDERS COMPANY, Ltd., 9, Henrietta Street, London, W.C.2.

A fine product from the celebrated laboratories of E. SCHERING—a guarantee of purity and reliability.

TRADE **ATOPHAN** MARK.

Immediately soothes the pain and rapidly alleviates Acute and Chronic Rheumatism, Gout, Ischias, Neuralgia, Lumbago, Iritis, Pleuritis, etc. **The immediate use of Atophan for Acute Articular Rheumatism prevents cardiac complications** and its administration is not accompanied by the ill-effects associated with salicylic therapy.

Supplied also for Injection in the form of:

ATOPHANYL

Original Packings:

ATOPHAN: Tubes of 20 Tablets each of 7½ grs. **ATOPHANYL:** Cartons of 5 Ampoules each 5 c.cm.

Clinical Packings (for Hospitals and Clinics only): **ATOPHAN:** Bottles of 500 Tablets each of 7½ grs.

Samples and Literature on request from the Importers:—

THE STRAPPING THAT GRIPS.

LESLIES ZŌPLA Zinc Oxide Plaster

A tenaciously self-adhesive Plaster which will not slip, however great the strain. Antiseptic.

NON-IRRITATING AND THOROUGHLY RELIABLE.

On white and flesh colour cloths, also on holland, on spools and in rolls. SAMPLES ON REQUEST.

USE ALSO OUR HOLLAND STRAPPING. THE ORIGINAL AND STILL THE BEST.

LESLIES LTD., High Street, Walthamstow, LONDON, E.17.

VALENTINE'S PREPARATION
NUTRIO PERME
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Valentine's Meat-Juice

In **Hospital** and **Private Practice** during **Epidemics** and **in their own persons** when ill, **Physicians** have demonstrated the **Value** of **Valentine's Meat-Juice** in **Sustaining** and **Strengthening** the weakened **Vital Forces.**

Pneumonia *and* Influenza.

Cavalier Dr. Enrico Ballerini, *Late Surgeon to the Hospital of Rome, Italy:* "I have used VALENTINE'S MEAT-JUICE in the treatment of patients and also personally after having been ill with Influenza, and I must say it is an excellent tonic in conditions of great organic weakness. I have prescribed it with the greatest satisfaction for convalescents and invalids restricted to a liquid diet."

Edward C. Seufert, M.D., *Professor Histology and Pathology, Illinois Medical College, Chicago:* "I have always been a user of the valuable preparation, VALENTINE'S MEAT-JUICE. The best results that I have obtained from it have been in Typhoid Fever and Broncho-Pneumonia of Children. I believe that the samples sent helped to save the child of one of my students at the College."

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
RICHMOND, VIRGINIA, U.S.A.

SIMPLE MEDICAL YEAR BOOK.

Demy 8vo, strongly bound, **14s. 9d.** net, post free.

This Year Book is really a Private Annual Ledger, in that it contains a concise record of *all Professional Expenses*, as well as *Receipts*, in a most convenient form and can be adopted by all Practitioners, whatever their systems of book-keeping may be, *at any time of the year*.

A page is allotted to each week, and so apportioned that, besides indicating the daily Fees Earned, Cash and Ledger Receipts, *all the various sources of Professional Expenditure* are classified and tabulated, thus clearly showing in a systematic way at any moment during the year, the total *Receipts and Expenditure*, at a minimum outlay of time and trouble. It is interleaved with stout white blotting paper (for pencil notes, &c.), and at the end pages are reserved for Quarterly Abstracts, &c., Summary or Balance Sheet.

Many professional men—doctors especially—experience great difficulty in estimating their expenditure, and also their net income, whilst the *filling up of the Income Tax Assessment Form* is a task which involves considerable time. The Simple Medical Year Book provides an easy means of overcoming these difficulties and contains useful information on allowable Income Tax deductions, &c.

The Simple Medical Year Book will prove *invaluable* to all practitioners.

CANCER: Its Cause, Treatment and Prevention.

By **A. T. BRAND,** M.D., C.M., V.D., Physician, Driffield Poor Law Infirmary; late Major R.A.M.C. **8s. 6d.** net, post free 9s. 3d.

" Dr. Brand states his opinions with clearness and confidence . . . it is a strong presentment of the case, and the personal experiences of Dr. Brand are set forward in a convincing manner."—LANCET.

THE USE OF THE BRAKES

A good driver uses the brakes but little. Do not wait until the last minute to slow down. Take your foot off the accelerator beforehand. Let the car slow down of its own accord. Do *not* withdraw the clutch every time you brake. It should be disengaged only when about to stop, or when changing gear. Use the hand brake alternately with the foot brake. Attention to these points will spare the transmission and add to the life and efficiency of the car. Run on "BP," the British Petrol, and you will keep your engine clean and powerful, and your costs low.

Heard at the barber's

Yes, sir, I meet every type of man expressing every shade of opinion. This little shop becomes the forum for the weighing of evidence on every subject under the sun. We have heated arguments, too—of course, always in the right spirit, I see to that. But there's one subject on which opinion is absolutely unanimous. When the quality of razors is discussed, everyone agrees that you cannot better a Kropp. Naturally I only use a Kropp, and I know why my customers won't be shaved with any other razor. It's because the Kropp is manufactured from the very finest Sheffield steel and its keen edge will sweep smoothly, quickly, unerringly over the most stubbly chin ; it can make shaving a real pleasure.

In case, black handle, **10/6** ; ivory handle, **18/-**.

Intestinal Disinfection

No. 1.

In subsequent advertisements we shall discuss and indicate the various conditions in which KEROL Capsules have been proved successful.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession

KEROL LTD.
(Successors to Quibell Bros. Ltd.),
102, Castlegate,
NEWARK

ALIMENTARY TOXÆMIAS

Putrefactive bacteria increase in numbers in the intestine as age advances. They are relatively scanty in the young child, but after middle life are usually present in considerable numbers. Of the micro-organisms concerned, proteolytic anaerobes are probably the most important.

In individuals with a normal intestine and free evacuations they may do little harm, but in those subject to intestinal catarrh these putrefactive bacteria become more numerous and active, their products are formed in greater quantity and are more freely absorbed, and the condition of alimentary toxæmia results. The manifestations of this state are very protean; *e.g.*, 'rheumatic' conditions, digestive upset, neurasthenia and neuralgias, increased blood pressure and its complications, and many others. The treatment, in the first place, obviously should be *intestinal disinfection.* For this purpose nothing surpasses the use of KEROL CAPSULES. They have solved for years the question of disinfection of the alimentary tract. They definitely reduce the bacterial content of the intestine, as shown by the reduction in *B. coli* by 99% when the Capsules are regularly administered for a period of from seven to ten days.

We have from time to time published several Booklets containing clinical evidence as to their value, and these we will gladly forward on receipt of a postcard to any member of the Medical Profession.

KEROL CAPSULES

ANAPHYLACTINE

(In Boxes of 2 Ampoules of 1 c.c.)

FOR SUBCUTANEOUS INJECTION.

- A polyvalent protein extract containing active substances only, prepared from the formula and under the control of Dr. V. G. Brabant, of Brussels.
- Increased therapeutic activity is induced in anaphylaxis and in such diseases as **Asthma, Eczema, Psoriasis, Urticaria, Chronic Rheumatism, etc.** No local reactions have ever been reported.
- In eczema or psoriasis a notable improvement follows each injection, the lesions clearing gradually to finally disappear altogether.
- A large percentage of cases of Asthma respond to injections of Anaphylactine. The paroxysms decrease in frequency and severity, with corresponding improvement in other symptoms. In the major portion of cases the gradual improvement will finally result in complete cure.
- In chronic rheumatism and migraine satisfactory results have also been obtained.

O. & S

PETROLEUM

IN THE TREATMENT OF

INTESTINAL DISORDERS

Purified Petroleum in one form or another is becoming more and more widely employed in the treatment of intestinal disorders associated with toxaemia. To obtain the best results, the petroleum should be not only non-irritating and free from all impurities, but it should preferably be in the form of an emulsion. In this form, the minutely divided petroleum globules mingle freely with the intestinal contents, and are more widely and evenly distributed throughout the entire intestinal tract. Maximum lubrication is thus assured and the characteristic action of the oil obtained with greater uniformity.

Angier's Emulsion is made with a specially purified petroleum of just the right degree of viscosity. It is a perfect Emulsion of cream-like appearance and consistency, and mixes instantly with water and other liquids. Pleasant to the palate and remarkably well borne by sensitive stomachs, it can be administered either undiluted or in any suitable vehicle. It has been found that patients who cannot tolerate clear petroleum are able to take Angier's Emulsion without the slightest difficulty, and continue indefinitely without ever developing an antipathy to it. Angier's Emulsion will also be found most useful as a vehicle for the administration of intestinal antiseptics or astringents, for which purpose it is eminently suitable.

"After long experience of many forms of paraffin and petroleum, both in the character of emulsions and otherwise, I have found none so satisfactory to the patient as Angier's Petroleum Emulsion."—M.D., D.Sc., M.A.

Trade Mark **'BISMOSTAB'** Brand

METALLIC BISMUTH SUSPENSION

BOOTS

BISMOSTAB is a most potent spirillicide consisting of a suspension of metallic Bismuth in isotonic Glucose solution. Thorough clinical trials have shown that Bismostab is

1. WELL TOLERATED.
2. NON-IRRITANT.
3. THERAPEUTICALLY VERY ACTIVE.

The preparation is supplied in sterile rubber-capped vials *ready for use*—each cubic centimetre of solution containing 0·2 gm. of Bismuth Metal.

SPECIAL LITERATURE ON APPLICATION.

SOLE MANUFACTURERS:

BOOTS PURE DRUG CO. LTD.

STATION STREET,——NOTTINGHAM.

Telephone: Nottingham 7000.

ADEQUATE LACTATION OBTAINED BY A SIMPLE AND NATURAL MEANS.

OVALTINE

TONIC FOOD BEVERAGE

This delicious combination of choice food elements—ripe barley malt, creamy milk, fresh eggs and the purest cocoa—renders breast-feeding both easy and certain. Practical clinical experience proves that when " Ovaltine " is commenced during the 8th month of pregnancy a rich secretion of milk is assured. Continued throughout the nursing period " Ovaltine " maintains an ample flow of milk; the child thus enjoys the advantages which only breast-feeding can confer, whilst the health of the mother is protected against over-strain.

A Complete Food. Obtainable of all Pharmacists.

A liberal supply for Clinical Trial sent free on request.

A. WANDER, Ltd., 184, Queen's Gate, London, S.W. 7.

Works : KING'S LANGLEY, HERTS.

M 163

CRISTOLAX

" Cristolax " is a new, improved and entirely satisfactory method of administering liquid paraffin, eliminating the disadvantages of the uncombined oil, and adding to the efficacy of the treatment. It ensures natural and easy movement of the bowels and lubricates the whole digestive tract, enabling it to recover its normal tone, and thus obviating the disturbing after effects which follow the use of ordinary aperients.

" Cristolax " contains 50 per cent. liquid paraffin and 50 per cent. " Wander " Malt Extract and is presented in the form of granular crystals. Extremely pleasant to taste, it mixes freely with milk or water, without separation of the oil. The highly nutritive, digestive and milk-modifying properties of the " Wander " Malt Extract are retained unimpaired, thus making the preparation a valuable addition to infant feeds.

It mixes thoroughly with the intestinal content, preventing formation of Scybala, and does not cause over-lubrication. When added to cow's milk " Cristolax " prevents the formation of indigestible curds, and supplies the deficiency of carbohydrate. It can be administered to infants in the usual bottle feeds.

A liberal supply for Clinical Trial sent free on request.

PALLAS ATHENA

A. WANDER, Ltd., 184, Queen's Gate, London, S.W. 7.

Trufood is the only scientific alternative for human milk

Whatever claims are made for other infants' foods, none, when subjected to the test of analysis, can show the same close approximation to breast milk as Humanised Trufood. The latter, as the following figures clearly prove, makes available for the first time a product which, whilst containing nothing but the solids of milk, is practically identical in composition with human milk, when reconstituted with water.

ANALYSIS

	Breast Milk	*Cow's Milk*	*Humanised Trufood*
	%	%	%
Lactose	6.5	4.7	6.25
Fat	3.3	3.5	3.45
Casein	0.9	3.0	0.80*
Lactalbumen	0.4	0.3	0.60
Salts	0.2	0.8	0.65
Water	88.7	87.7	88.25
	100.00	100.00	100.00

Freedom from Starch.—No Starch or products of starch conversion occur in Trufood. The only carbo-hydrate present is milk sugar. This is of importance since all authorities are agreed that starch, whether free or converted, is harmful in infant feeding.

You are invited to apply for reproduction of actual photograph (in colours) of a recent incubation test of various milks. This is obtainable by post.

Samples adequate for full clinical trial together with descriptive literature on request.

TRUFOOD

THE ONLY SCIENTIFIC ALTERNATIVE
FOR BREAST FEEDING

TRUFOOD LTD., THE CREAMERIES, WRENBURY, nr. NANTWICH, CHESHIRE

"MARSHALL'S"

THE list of Antiseptic substances is a fairly comprehensive one. The number of antiseptics capable of practical and easy application are few.

First and perhaps foremost of these is undoubtedly LYSOL—a saponaceous preparation of the three cresols—*ortho*-cresol, *meta*-cresol, and *para*-cresol.

These cresols vary in their bactericidal activity, and much depends upon the right selection when used in manufacturing.

The production of antiseptics and disinfectants that shall fulfil all requirements is the outcome of lengthy research and skilful manufacture—they cannot be prepared and standardised by small inexperienced makers.

For this reason, and owing to the number of substitutes offered to Surgeons and Doctors, it is necessary to specify " MARSHALL'S " when ordering or prescribing " Lysol " to ensure the genuine original product, which is guaranteed free from causticity and the impurities which give rise to irritation and frequently cause intense pain.

MARSHALL'S LYSOL does not attack the skin or numb the hands. Its use generally will be found quite agreeable.

Marshall's Lysol can be obtained in all the Dominions and Dependencies.

A four-ounce Bottle will be sent upon request by the Sole Makers—

LYSOL LIMITED, LONDON, S.W. 20

CHATELAIN'S LABORATORIES

'BYNIN' Amara

"A Distinct Advance on Easton's Syrup."

——*The 'Lancet.'*

'Bynin' Amara is an analogue of the well-known Easton's Syrup, but it is therapeutically much superior to that preparation. The syrup is replaced by 'Bynin,' pure active Liquid Malt, which affords a far better vehicle than the former, as it is actively digestive and nutritive. An added advantage is that the nauseous flavour of Easton's Syrup is effectively masked, whilst there is no possibility of sugar crystallising out and carrying down with it the active alkaloidal principles.

DOSE FOR ADULTS—A dessertspoonful to a tablespoonful in twice the quantity of water twice or on occasion three times daily.

Further particulars and free sample will be sent on request.

Allen & Hanburys Ltd.
37 Lombard Street, LONDON, E.C. 3.

TRADE 'KEPLER' MARK

COD LIVER OIL WITH MALT EXTRACT

PREPARED from British winter-malted barley and cod liver oil, specially selected for its VITAMIN Content. Physiological tests show the presence of Vitamins A and B in active condition. Being entirely free from any fishy odour and taste, this palatable combination is taken with avidity by children and invalids. It is of particular value in convalescence, and is useful in all cases where there is impairment of appetite and tendency to lose flesh. Whenever a flesh-forming and tissue-repairing addition to the diet is required, 'KEPLER' COD LIVER OIL WITH MALT EXTRACT may be prescribed.

Some 'Fairchild' Products

'Panopepton'

AN IDEAL FOOD FOR INVALIDS

'PANOPEPTON' is the food par excellence for invalids; in all acute diseases, fevers, etc.; in convalescence, for the large class of persons who, from feebleness or deranged digestion, or antipathy to ordinary foods, require a fluid, agreeable, and quickly assimilable food.

Supplied in 12-oz. bottles.

'Pepsencia'

'PEPSENCIA' is an ever-ready digestive fluid, containing all the soluble constituents of the gastric juice, preserved in an agreeable aromatic menstruum. It represents both the peptic and milk curdling ferments obtained directly from the fresh peptic glands.

Supplied in 4-oz., 8-oz., 16-oz., and W. Qts.

'Zymine' Peptonising Tubes

FOR THE PREPARATION OF PEPTONISED MILK
AND OTHER PREDIGESTED FOOD FOR THE SICK

Peptonised Milk prepared with 'Zymine' Peptonising Tubes is a perfectly digestible and absorbable food. Its use precludes all accumulation of unassimilable matter in the intestinal tract.

Supplied in boxes containing 6 and 12 tubes.

Peptogenic Milk Powder

FOR MODIFYING AND HUMANISING COWS' MILK
FOR INFANT FEEDING

Humanised Milk prepared with PEPTOGENIC MILK POWDER is remarkably like mother's milk in all particulars; in physical properties, in colour and taste, and in the percentage of nutritive constituents; in its digestibility, its behaviour with acid, with rennet, and in the infant's stomach.

Supplied in Two Sizes.

To all Readers of "THE LANCET."

AT the close of the year may we refer to our privileged association with you during 1924. After introducing our "Unlimited Indemnity Policy," which was freely taken up, we brought out our "Comprehensive Policy" which included not only Unlimited Indemnity but full protection respecting contents of House and Surgery, Motor Car(s) and Sickness and Accident. We have hardly ever submitted the policy for consideration to enquirers without it having been taken up. It can be completed at any time and full rebates allowed on existing insurances, and the basis of the Premium is **£20.**

Lately the Policy has been improved in respect of the absence of restrictive conditions and premiums may now be paid quarterly or half-yearly. Owing to the large number of Doctors insured during 1924, every proposer will receive the fullest advantage of the co-operative and mutual principles introduced, and as other benefits may be offered may we say too that the Company's income has more than doubled during the year, and as instancing the value of the business underwritten the loss ratio for 1923 was lower than that of any composite Company.

We feel sure that the above will be satisfactory to you, and we beg you to call upon us, or to write for details.

The Food of Royal Infants

Robb's

NURSERY BISCUITS AND BISCUIT POWDER

ROBB'S NURSERY BISCUITS have been used in the British Royal Nurseries, and are recommended by the most eminent Accoucheurs and Physicians throughout the world as being *the most reliable food for infants over 6 or 7 months.* They are nourishing and invigorating and, *being rich in dextrine,* supply a valuable Food in a form that is most acceptable to the requirements of infantile digestion. They are especially recommended as a substitute for the ordinary Bread and Milk Diet for young children; also as a sustaining Food for Convalescents, the aged, and all persons of weak digestion.

ROBB'S NURSERY BISCUIT POWDER is recommended when a substitute is required *for use in feeding bottle.*

ROBB'S DIGESTIVE RUSKS, TOPS and BOTTOMS and CHARCOAL BISCUITS are also specially recommended.

SEND US A CARD,

and a generous Free Sample of ROBB'S Nursery Biscuits and Biscuit Powder will be forwarded, with descriptive Booklet, price list, etc.

FOR INTERNAL TREATMENT OF GONORRHŒA, URETHRITIS AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

Santal Midy Capsules have been prescribed with uniform success for over 30 years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations.

SANTAL MIDY

There is a marked absence of Gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permit its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-urinary Tract. The capsules contain [illegible] drops, and usually [illegible] to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Générale, 8, Rue Vivienne, Paris, and sold by most Chemists and wholesale Druggists throughout the world.

NONSPI

AN ANTISEPTIC LIQUID

Harmlessly Ends Armpit Perspiration

Is More Than a Mere Deodorant

Send for Free Testing Sample and make convincing personal test.

BY causing underarm perspiration to pass off through other pores where there is better evaporation, this pure, unscented antiseptic liquid acts as a harmless remedy for the perspiration itself, in addition to destroying all trace of perspiration odor.

NONSPI has for years been used by innumerable women everywhere. It is endorsed by many members of the medical profession.

Physicians, surgeons and nurses find the regular use of NONSPI insures immaculate underarm hygiene and personal comfort, so essential to those who come in contact with the ill and sensitive.

Those who perspire very little depend upon the occasional application of NONSPI as a preventive of perspiration odor, which so frequently exists, though perspiration is not excessive.

You can use it and recommend it to your patients with absolute confidence.

SAMPLES FREE to the MEMBERS of the MEDICAL PROFESSION WITHIN THE UNITED KINGDOM.

Until a very short time ago, the bottle-fed baby and his mother were at a distinct disadvantage. Feeding time was attended with various discomforts, then thought inseparable from the bottle method.

The new Cow & Gate Feeder—simple, efficient and hygienic—is the outcome of careful study of Baby's sucking power; no leakage, no hand-tiring, no guess-work.

There are numerous new and important features in the Cow & Gate Feeder The flow of food can be nicely regulated by the zig-zag groove in the octagonal glass-stopper (secured by a moveable rustless clip so that Baby cannot remove it.) Clearly marked for ounces and table-spoons. Patent pure rubber teat, internally ribbed so that it has only to be rolled between the fingers to be cleared of any secreted food, but cannot be slipped off by Baby. Bottle has a flat base, and can be stood without food reaching the teat.

Stopper, clip and teat can be removed by Mother in three seconds, and the bottle flushed from end to end. The whole Feeder is well-balanced, easily held, and cannot get out of order in any way. It realises the dream of thousands of Mothers and Nurses.

Cow & Gate STOPPERED Feeder

BOVRIL MEDICAL AGENCY, LIMITED,

ALDINE HOUSE, 10-13, Bedford Street, Strand, London, W.C. 2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. Telephone: GERRARD 3543 (Three Lines).

Established by BOVRIL, LIMITED, to provide an efficient and Reliable Transfer Service for the Profession at Minimum Charges.

Under the Personal Direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES.

An Accountant's Certified Report is required in respect of every Practice or Partnership the disposal of which is undertaken by the Agency.

The commission chargeable in respect of any Practice in Great Britain placed exclusively in the hands of the Agency for transfer has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50). In the case of Foreign and Colonial Practices similarly placed the maximum is seventy-five pounds (£75).

NO CHARGE IS MADE TO PRINCIPALS FOR THE INTRODUCTION OF LOCUM TENENS OR ASSISTANTS.

Accountancy and Legal Services furnished by the Agency, where desired, at moderate inclusive charges.

PRACTICES AND PARTNERSHIPS FOR SALE.

1. NORTH-EAST COAST. — Important Seaport Town. Growing Middle- and good Industrial class PRACTICE, held by Vendor 5½ years, and producing between £750 and £800. Panel of 420. Advice and medicine 3s., 3s. 6d., and 5s. Visits and medicine 3s. 6d. to 7s. 6d. About 20 cases of Midwifery a year at 2 to 5 guineas. A motor-car is not essential but advantageous. Good house with 2 reception-rooms, 5 bedrooms, bathroom, &c., excellent waiting- and consulting-rooms. Small garden back and front—both very open. Is the Vendor's own copyhold with a ground rent of £5 5s., and is estimated to be worth £1500. There are two Hospitals in the town, and every prospect of the purchaser securing an appointment on the Staff in the near future. Vendor has secured an appointment which he must take up shortly and is therefore prepared to accept £2000 for the house and practice.

2. DORSET. — Country Practice. — PARTNERSHIP. — A Half Share in a Country Practice producing for the last year about £950, but increasing and offering scope for development. Present panel only 400. Nearest opposition 6 miles. Advice and medicine 3s. 6d. to 6s. Visits and medicine 5s. to 12s. 6d. Lowest Midwifery 3 guineas. Small semi-detached house with 2 reception and 3 bedrooms, bathroom, 1½ acres of garden; rent £26. Larger house, on rental, will be vacant shortly. Hunting, shooting, fishing. Bracing climate. Premium £750.

3. PARTNERSHIP with SURGICAL SCOPE. — SOUTH MIDLANDS.—Pleasant Hospital Town. A One-third Share (with increase up to one-half later) is for disposal in a sound Better- and Middle-class non-dispensing Practice. Average income for last 3 years £3,570, including a panel of 1400. Fees for advice 3s. 6d. and 5s.; visits 5s., 7s., and a few at 1 guinea. About 50 Midwiferies a year at from 3 to 10 guineas. Choice of 2 good and well-situated houses, with gardens, and lit with electric light, on lease. There is an up-to-date hospital in the town, and the incoming partner would almost certainly be appointed to the Staff. The purchaser should be well qualified and experienced in major surgery. Excellent schools and exceptional social advantages. Sport of all kinds. Premium for the third share £2500.

4. WARWICKSHIRE.—Unopposed old-established PRACTICE, situated in the centre of hunting district, within 10 miles of a large town. Average receipts £1650, including appointments. Panel of 1100. Visits 3s. 6d. to 21s. Midwifery 2 to 5 guineas; 50 cases. Very good house, ample accommodation, bathroom, tennis lawn. Water laid on. Electric light. Freehold. Entirely redecorated. Price £2500. Premium £2000 cash, or £2200 by instalments. Plenty of social life.

5. LANCASHIRE (LAKE DISTRICT).—Unopposed very old-established PRACTICE, situated in a small Market Town in a delightful agricultural and residential district (population over 5000), close to the Sea. Cash receipts for the last three years average £2250, including appointments worth £150 and panel of 800. Held 8 years. Nearest opposition 3 miles. Railway station 2 miles. Visits 2s. 6d. to 21s. Midwifery 2 to 10 guineas; about 50 cases yearly. Pleasant house, containing waiting- and consulting-rooms, 2 reception and 6 bedrooms, bathroom (h. & c.), good garden, garage; rent £45 on lease. Premium £3375, £2000 down. Satisfactory reasons for selling.

6. PARTNERSHIP.—A One-half Share is offered in an old-established Practice, situated in a Hospital Town within 50 miles of London (North). The average income is about £2000, and there is a panel of nearly 800. Advice and medicine from 2s. 6d. Very little Midwifery. Double-fronted house, detached, and with ample accommodation. Price £2000, of which half can remain on mortgage. There is an up-to-date Hospital and an early vacancy on the Staff is probable. Premium 2 years' purchase.

7. NORTHERN CATHEDRAL CITY. — Old-established Middle- and Working-class PRACTICE. Average income for the last three years about £1400, including panel of 1000. Visits from 5s. to 7s. 6d. Midwifery 3 guineas upwards; about 30 cases yearly. 12 roomed house, with garden. Will be let on lease at £60 p.a., or sold for £1100. Premium £2100.

8. SOUTH LONDON.—Residential Suburb.—PARTNERSHIP.—A One-third Share (to commence with) is offered in a very old-established General Practice. Income for the last year just over £3000, with scope. Panel of about 700. Fees from 3s. 6d. to 10s. 6d. A few Midwifery cases from 3 guineas. A suitable house can be secured. Purchaser must be a Cambridge Graduate. Premium 2 years' purchase.

9. LONDON, S.W. (Riverside Suburb).—Old-established Better- and Middle-class PRACTICE, non-panel and mainly non-dispensing. Average income for the last three years £1656. Visits 3s. 6d. to 10s. 6d. About 10 cases of Midwifery yearly at from 3 to 10 guineas. Commodious house, with good garden, garage. Will be let on rental of £160, or the leasehold sold for £2500. Premium £3000, payable £1500 down.

10. LONDON, N.W.—Non-panel Middle-class PRACTICE, to which is attached a Nursing Home. Total average income for the last three years £1500. Advice and medicine 3s. 6d. to 5s. Visits and medicine 5s. to 10s. 6d. About 40 cases of Midwifery a year from 3 to 5 guineas. Large, well-situated non-basement house, held on lease with 60 years to run, with a ground rent of £10 per annum. Price £1500. Premium £2250, or near offer.

11. LONDON, NORTH.—Old-established PRACTICE, producing an income of £1400 a year, including appointments worth £320. Panel of 320, but this can be largely increased if desired. Visits and medicine 3s. 6d. to 7s. 6d. Practice is easily worked, with no conveyance. Nice house, in good decorative repair, with fair garden; rent £125. Garage can be let off at £26 or £54. Premium £2000.

12. WEST OF ENGLAND.— Residential Town.— A well-qualified and experienced man can secure a PARTNERSHIP, with ultimate Succession, in a good Consulting Practice. The present income is only about £1500 a year, but there is large scope for increase, particularly if general practice is also undertaken. Fees mainly 1 and 2 guineas and a few at 10s. 6d. Choice of houses, on rental and to purchase. Premium for the half share £1500.

13. EASTERN COUNTIES.—Within 4 hours' run of London. Practically unopposed PRACTICE, old established and situated in a very pretty Country Town with beautiful surroundings. Cash receipts for last financial year £2022, including appt. of £50 and panel of 500. Visits up to 21s. Very little Midwifery. Car optional. Railway station. Charming residence (with ample accommodation) in its own grounds of ¾ of an acre. Price £2900, all of which can remain on mortgage at 5 per cent. Premium for Practice £2500. Excellent prospects. Tennis, golf, hunting, shooting, &c.

14. SOUTH OF ENGLAND.—Coast Town.— A FOURTH PARTNER is required in an increasing Mixed-class Practice. Average income about £5000 per annum, including panel of nearly 3000 and various appointments. The share offered for disposal will produce about £800 per annum. Comfortable rooms at the Surgery are available for the ingoing partner; rent £60 p.a. Premium 2 years' purchase.

15. RESIDENTIAL TOWN, within 100 miles of London.—Non-dispensing, chiefly better-class PRACTICE, producing an income of about £2000 a year, including small panel of about 600. Fees from 2s. 6d. to 21s., mainly 7s. 6d. upwards. Only a few cases of Midwifery yearly at from 2 to 25 guineas. Attractive and commodious house (3 reception, 7 bedrooms, &c., garden) on rental at £100 p.a. Good society, and sport of all kinds. Premium £4000, payable £2000 cash and £2000 by instalments.

Profits accruing to Bovril, Ltd., from the Agency will be allocated amongst recognised Medical Charities

Full Schedule of Terms and Conditions will be forwarded on application.

PRINTED by HAZELL, WATSON & VINEY, LD., 52, Long Acre, W.C.2, and PUBLISHED by the PROPRIETORS, WAKLEY & SON (1912) LTD., at No. 423, Strand, and No. 1, Bedford Street, Strand, in the County of London.—Saturday, Dec. 27, 1924

THIS PREPARATION IS NOW OBTAINABLE IN 5-oz. BOTTLES.

MIST. HEPATICA CONC. (HEWLETT'S)

COMPOSITION.—Ext. Cascaræ, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.

This preparation does not come under the Dangerous Drugs Act.

THIS excellent compound, first introduced as a general **aperient** and **cholagogue**, has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. **In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.**

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease and in pregnancy, or in the constipation due to sedentary habits, to a deficiency of intestinal secretion and of peristalsis, the mixture can be prescribed with wonderful effect.

The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

Price in England, 12/6 per lb.

Please write: "Mist. Hepatica Conc. (HEWLETT'S)" to ensure obtaining this Preparation.

This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

Hyperchlorhydria and Associated Conditions

TRADE MARK **ALOCOL** BRAND

Colloidal Hydroxide of Aluminium

Modern medical experience has proven that while the usual alkalis and oxides possess power for neutralizing the normal or abnormal acids of the stomach their action is only symptomatic and transitory. They may give momentary relief to the painful condition, but they also have the effect of aggravating the morbid condition. For this reason they are distinctly contra-indicated, especially in stubborn cases.

"Alocol" does not neutralize acid; it absorbs the excess colloido-chemically and at the same time leaves a sufficiency for normal gastric digestion. The outstanding advantage of "Alocol" as an antacid is that it removes from the system the causative acid radicle (Cl), instead of merely temporarily neutralizing it. "Alocol" can be used for prolonged periods without the slightest harmful effect.

A supply for clinical trial with full descriptive literature sent free on request.

"Alocol" is indicated in all conditions in which diagnosis reveals high gastric acidity. It is particularly valuable in the treatment of chronic affections of the stomach, the dyspepsias, especially those of pregnancy, gastric and duodenal ulcer, gastrosuccorrhea and in conditions characterized by gastralgia, pyrosis, flatulence, acid eructation and other symptoms common to gastric disease.

When rheumatism grips, the *sustained* heat of Antiphlogistine soothes

AS far as is known to Medical Science there is no *real* cure for Rheumatism. Osler says "hot applications are soothing"—and when Rheumatism grips, especially in joints and muscles, the *self-generated* and *sustained* heat of Antiphlogistine brings blessed relief.

Apply Antiphlogistine hot and thick

—as hot as can be borne comfortably by the patient. Once in position and bound snugly with an outer bandage Antiphlogistine will *produce* and sustain heat upwards to 24 hours.

The scientific reason for this is that the large c. p. Glycerine content in Antiphlogistine, acting with the fluids of the tissues, especially when joint swelling is present, sets up a natural generation of heat.

We do not claim that Antiphlogistine will cure Rheumatism, but it does diminish pain and this is a great relief to the patient.

Let us send you *Free* Literature.

Buenos Aires, Barcelona, Montreal, Mexico City

Antiphlogistine
TRADE MARK
"Promotes Osmosis"

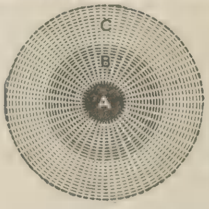

Diagram represents inflamed area. In zone "C" blood is flowing freely through underlying vessels. This forms a current away from the Antiphlogistine, whose liquid contents, therefore, follow the line of least resistance and enter the circulation through the physical process of endosmosis. In zone "A" there is stasis, no current tending to overcome Antiphlogistine's hygroscopic property. The line of least resistance for the liquid exudate is therefore, in the direction of the Antiphlogistine. In obedience to the same law exosmosis is going [illegible] in this zone, and the excess of moisture is thus accounted for.

Antiphlogistine poultice after application. Center moist. Periphery virtually dry.
